**Use of potassium stannochloride dihydrate  $\text{K}_2\text{SnCl}_4 \cdot 2\text{H}_2\text{O}$  in determination of iron.** E. VOYATZAKIS (Praktika, 1934, 9, 108—111; Chem. Zentr., 1935, i, 3317).—To the strongly acid ( $\text{HCl}$ )  $\text{Fe}^{+++}$  solution,  $\text{NaHCO}_3$  is added, and then an excess of  $\text{K}_2\text{SnCl}_4 \cdot 2\text{H}_2\text{O}$  (I) (prep. described). The excess of (I) is titrated back with 0.01N-I. J. S. A.

**Determination of iron in phosphorites and apatites.**—See B., 1936, 144.

**Oxidimetric determination of molybdenum. I. Vanadate method.** R. LANG and S. GOTTLIER (Z. anal. Chem., 1936, 104, 1—16).—A neutral  $\text{MoO}_4^{--}$  solution is acidified with 15—20 vol.-% of conc.  $\text{HCl}$ , and 0.2N- $\text{SnCl}_2$  is added until no further brown coloration occurs on each addition, reducing  $\text{Mo}^{\text{VI}}$  to  $\text{Mo}^{\text{V}}$ . The excess of  $\text{SnCl}_2$ , but not  $\text{Mo}^{\text{V}}$ , is oxidised by adding aq.  $\text{Br} + \text{KBr}$ ,  $\text{Br}$  being removed by an equal vol. of 0.3N- $\text{As}_2\text{O}_3$ .  $\text{NaF}$  is added, and then  $\text{NHPh}_2$  in  $\text{H}_3\text{PO}_4$  as indicator.  $\text{Mo}^{\text{V}}$  is oxidised by addition of 0.1N- $\text{NH}_4\text{VO}_3$  (I), the excess of which is titrated back with  $\text{FeSO}_4$ . Alternatively, after addition of  $\text{As}_2\text{O}_3$ , the  $\text{Mo}^{\text{V}}$  may be titrated directly with (I), previously oxidised diphenylamine-sulphonic acid being added as indicator shortly before the end-point. The acidity during reduction must be as stated to avoid reduction to  $\text{Mo}^{\text{III}}$  or  $\text{Mo}^{\text{IV}}$ , which oxidises directly to  $\text{Mo}^{\text{VI}}$  with  $\text{Br}$ . Neutral salts or non-reducible metals do not interfere. In presence of  $\text{Fe}$  and  $\text{V}$  the method is impracticable, due to oxidation of  $\text{Mo}^{\text{V}}$  by  $\text{Fe}^{\text{III}}$  and  $\text{V}^{\text{IV}}$ . Large amounts of  $\text{Cu}$  interfere similarly.  $\text{Mo}$  may be determined in presence of  $\text{W}$  by adding  $\text{NaF}$  before reduction to keep  $\text{WO}_3$  in solution; a trace of  $\text{Cu}$  is added to catalyse the reoxidation of  $\text{W}$  compounds by  $\text{Br}$ . J. S. A.

**Reduction of uranyl ion in the uranyl oxalate actinometer.** E. C. PITZER, N. E. GORDON, and

D. A. WILSON (J. Amer. Chem. Soc., 1936, 58, 67—70).—A method for determining  $\text{U}^{\text{IV}}$  in presence of  $\text{H}_2\text{C}_2\text{O}_4$  and  $\text{UO}_2^{++}$  is described. In the photolysis of actinometer solutions the complex undergoing unimol. decomp. is  $\text{UO}_2(\text{C}_2\text{O}_4)_2^{--}$ , and the source of  $\text{U}^{\text{IV}}$  is  $\text{UO}_2\text{C}_2\text{O}_4$ . The ionisation of the complex is discussed. E. S. H.

**Oxidation of stannous chloride by permanganate.** V. V. ZACHAROV and N. V. ZACHAROVA (J. Appl. Chem. Russ., 1935, 8, 1284—1286).— $\text{SnCl}_2$  may be titrated with  $\text{KMnO}_4$  in presence of  $\text{FeSO}_4$  and  $\text{H}_3\text{PO}_4$ . R. T.

**Determination of the thorium content of rocks.** W. D. URRY (J. Chem. Physics, 1936, 4, 34—40).—A method of measuring  $\text{Th}$  in quantities of the order of  $10^{-5}$ — $10^{-6}$  g. by determining the  $\alpha$ -particle activity of thoron ( $\text{Tn}$ ) in a streaming gas by a counter is described. It is possible to make a simultaneous determination of the  $\text{Pa/Ra}$  ratio in common rocks. M. S. B.

**Organic compounds as analytical reagents. II. Cinchonine iodide as reagent for determination of bismuth.** J. B. FICKLEN, I. L. NEWELL, and N. R. PIKE (Z. anal. Chem., 1936, 104, 30—34).—Cinchonine iodide is not strictly sp. for  $\text{Bi}$ . Data are given as to the interfering effect of other cations. J. S. A.

**Stable standardised gold solution.** W. C. WILLIAMS (J. Lab. Clin. Med., 1935, 80, 545—549).—Patterson's method (A., 1932, 225) is modified by use of 0.02N-KOH, the acid  $\text{Au}$  salt, and a solution of edestin for standardisation. CH. ABS. (p)

**Calorimetric apparatus.** W. A. ROTH (Chem. Fabr., 1936, 9, 10—12).—A summary of recent developments in calorimetry. J. W. S.

**Maquenne block.** R. P. JACQUEMAIN (Bull. Soc. chim., 1936, [v], 3, 142—143).—The disadvantages of the usual Maquenne block are reviewed. A Cr block is recommended. E. E. A.

**Combined hydrogen and helium liquefier.** B. V. ROLLIN (Proc. Physical Soc., 1936, 48, 18—27).—An apparatus needing only liquid air for the initial cooling, and designed for low-temp. laboratory experiments, is described. N. M. B.

**Semi-micro-Cottrell b.-p. apparatus.** M. L. WILLARD and D. E. CRABTREE (Ind. Eng. Chem. [Anal.], 1936, 8, 79—80).—The apparatus can be used with 5 c.c. of liquid and gives results accurate to  $0.1^\circ$ . E. S. H.

**Electrically-heated m.-p. apparatus.** E. DOWZARD and M. J. RUSSO (Ind. Eng. Chem. [Anal.], 1936, 8, 74—75).—The apparatus avoids the use of heating liquids and is suitable for substances with m.p.  $> 310^\circ$ , with a reproducibility of  $0.5^\circ$ . E. S. H.

**Stem correction for mercury thermometers.** M. EDENHOLM and G. OLSSON (IVA, 1935, 5—10; Chem. Zentr., 1935, i, 3692).—The formula  $\Delta t = n_1(t_a - t_c)/(k - n_1 + t_c)$ , where  $t_c$  = temp. of exposed stem, observed temp.,  $n_1$  = length of exposed stem in degrees, and  $1/k$  = apparent coeff. of cubical expansion, is proposed. H. N. R.

**General source of radiation for the visible and infra-red spectrum.** A. H. PFUND (Science, 1935, 82, 597—598). L. S. T.

**Curved quartz crystal X-ray spectrograph.** J. W. M. DuMOND and B. B. WATSON (Physical Rev., 1934, [ii], 46, 316—317). L. S. T.

**Large-aperture spectrograph suitable for the ultra-violet.** A. ARNULF and B. LYOT (Compt. rend., 1935, 201, 1480—1482).—A quartz spectrograph, aperture  $f/1$ , has been constructed using a spherical Al mirror in place of the usual objective.

T. G. P.

**Self-rectifying gas X-ray tube.** R. W. G. WYCKOFF and J. B. LAGSDIN (Rev. Sci. Instr., 1936, [ii], 7, 35—37).—An instrument previously described (Radiology, 1930, 15, 42) is improved. C. W. G.

**Simplified apparatus for fluorescence analysis.** A. KARSTEN (Zement, 1935, 24, 158—159; Chem. Zentr., 1935, i, 3315).—An apparatus, using activated metal electrodes, is described. H. N. R.

**Application of photo-electric methods to the Duboscq colorimeter.** G. BERNHEIM and G. REVILLON (Ann. Falsif., 1936, 29, 5—10).—The photo-electric cell described has a range of sensitiveness similar to that of the human eye, and consists of a small Fe plate supporting semi-conductors which are covered (by cathodic treatment) with a thin layer of an alloy of a precious metal. One of these is inserted under each of the eyepiece prisms of the Duboscq colorimeter, the two being connected through a milliammeter in opposition. Solutions tested and the corresponding max. relative matching errors are 0.6% 1.2, 0.05%  $\text{KMnO}_4$  10, 2%  $\text{CuSO}_4$  (in aq.  $\text{NH}_3$ ) 6, and 10 mg. per litre of methylene-blue 2.2%. J. G.

**Determinations with registering spherical cadmium cells.** M. BENDER (Physikal. Z., 1936, 37, 107—110).—Cd photo-cells can be used for determining the ultra-violet in sunlight. A. J. M.

**Differential refractometer.** D. RAU and W. E. ROSEVEARE (Ind. Eng. Chem. [Anal.], 1936, 8, 72—73).—The apparatus uses white light and has a sensitivity of  $5 \times 10^{-7}$ . It has been used to determine the concn. of aq. solutions with  $n=0.0004-0.002 > n$  for  $\text{H}_2\text{O}$ . The scale readings are nearly a linear function of the difference in  $n$ . E. S. H.

**Visual conductometry.** L. WOLF (Chem. Fabr., 1936, 9, 46—49).—Two galvanometer-Se-rectifier instruments are used, one in series with the titration cell and the other in parallel. The current in the main circuit is kept const. and the deflexion of the second galvanometer is observed after each addition of alkali. The accuracy can be increased by taking readings with different currents in the main circuit.

R. S.

**Directionally selective ion counter.** L. M. LANGER and R. T. COX (Rev. Sci. Instr., 1936, [ii], 7, 31—33).—A particle passing between a pair of parallel wire electrodes in a direction parallel to them produces a greater total discharge than one passing in another direction. C. W. G.

**Universal camera for electron diffraction at 10 100 kv.** H. J. YEARIAN and J. D. HOWE

(Rev. Sci. Instr., 1936, [ii], 7, 26—30).—Reflected or transmitted electron beams from a hot-filament cathode or from a discharge tube can be used. A wide range of temp. and exposures is available.

C. W. G.

**Ion sources for mass spectroscopy.** A. J. DEMPSTER (Rev. Sci. Instr., 1936, [ii], 7, 46—49; cf. A., 1935, 677).—A high-frequency alternating spark coupled inductively to a primary oscillating spark circuit is a more convenient source than a vac. vibrator or a large condenser discharge. C. W. G.

**Measurement of the breakdown and current-voltage characteristics of liquid dielectrics with direct potentials.** E. B. BAKER and H. A. BOLTZ (Rev. Sci. Instr., 1936, [ii], 7, 50—58).—Currents from  $10^{-16}$  to  $10^{-3}$  amp. can be measured. C. W. G.

**High-speed, high-sensitivity photo-electric potentiometer.** R. W. GILBERT (Rev. Sci. Instr., 1936, [ii], 7, 41—46).—The response to changes of input is instantaneous. C. W. G.

**Electro-ultra-filtration apparatus.** E. J. CZARNETZKY (Science, 1935, 82, 625—626).—An apparatus for the prep. of solutions of protein-Hg compounds is described. L. S. T.

**Mounting cell for the bulb type of glass electrode.** J. H. HIGHBERGER (J. Amer. Leather Chem. Assoc., 1936, 31, 32—34).—The apparatus described previously (A., 1935, 1097) is modified to permit the flushing of the saturated aq. KCl and the electrode chamber. D. W.

**Modified Gouy's balance for the accurate and quick measurement of diamagnetic susceptibilities.** M. B. NEVGI (Current Sci., 1935, 4, 403).—The modified instrument consists of two tubes, one of which is sealed and contains the paramagnetic substance and acts as a stopper to the other tube containing the diamagnetic specimen. An equation is deduced, and calc. results for nine org. substances are in good agreement with available data.

N. M. B.

**Utility of broken automatic pipettes.** B. N. SINGH and P. B. MATHUR (Science, 1935, 82, 626).

L. S. T.

**Apparatus for sugar and other titrations.** E. S. WEST (Ind. Eng. Chem. [Anal.], 1936, 8, 62).

E. S. H.

**Precision pycnometer for liquids.** S. T. YUSTER and L. H. REYERSON (Ind. Eng. Chem. [Anal.], 1936, 8, 61—62).—A modified apparatus is described.

E. S. H.

**Method of obtaining perfectly polished metallic surfaces.** P. JACQUET (Compt. rend., 1935, 201, 1473—1475; cf. B., 1935, 730).—The Cu specimen, polished in the ordinary way on fine emery, is made the anode in the electrolysis, at a suitable c.d., of aq.  $\text{H}_3\text{PO}_4$  or  $\text{H}_4\text{P}_2\text{O}_7$  containing at least 400 g. per litre, and maintained between  $15^\circ$  and  $25^\circ$ . T. G. P.

**Quick method of depositing polonium on silver.** M. D. WHITAKER, W. BJORKSTED, and A. C. G. MITCHELL (Physical Rev., 1934, [ii], 46, 629—630). L. S. T.

**Safety device for use with gas-heated Soxhlet.** J. C. MACRAE (Chem. and Ind., 1936, 53).—The device cuts off the gas supply if the  $H_2O$  supply to the condenser or bath begins to fail. E. S. H.

**Efficient fume hood [for laboratories].** G. W. MUHLEMAN (J. Chem. Educ., 1935, 12, 591).

L. S. T.

**Apparatus for producing vapours of constant concentration by evaporation of mixtures of liquids of different b.p.** E. V. ALEXEEVSKI and G. M. CHRAMOV (J. Appl. Chem. Russ., 1935, 8, 1319—1320).

R. T.

**Stirring apparatus for small amounts of liquid.** K. PACKENDORFF (J. pr. Chem., 1936, [ii], 144, 211—213).—An electrically operated plunger-stirrer, suitable for mixing small amounts of liquid in a gas-tight or evacuated tube, is described.

R. S. C.

**Low-pressure measurements.** W. GAEDE (Z. tech. Physik, 1934, 15, 664—668; Chem. Zentr., 1935, i, 3164).—A piece of Al foil is suspended by a quartz fibre in a glass vessel, the pressure and mol. wt. of the gas in the apparatus being deduced from observations of the vibration and damping of the Al. The range of operation is  $10$ — $10^{-7}$  mm. Hg. H. J. E.

**Laboratory hints.** A. VOSMAER (Chem. Weekblad, 1936, 33, 61—62).—The best methods for cutting different kinds of glass tubing and for cutting and boring glass plate are described.

D. R. D.

**Laboratory hints.** W. VAN TONGEREN (Chem. Weekblad, 1936, 33, 62).—A hole bored in the rubber ejector bulb of a wash-bottle is closed during use by means of a finger.

D. R. D.

**Ultramicrometer.** C. L. UTTERBACK and H. WIRTH (Physical Rev., 1934, [ii], 46, 323).—Changes in pressure of the order  $10^{-3}$  dyne per sq. cm. can be measured by the arrangement described. L. S. T.

**Organic liquids suitable for cloud expansion work.** D. D. LOUGHRIDGE and H. C. TRUEBLOOD (Physical Rev., 1934, [ii], 46, 323).—28 liquids have been studied with reference to their min. expansion ratio for condensation on  $\alpha$ -particle tracks.

L. S. T.

**Amplifier and recording apparatus for  $\alpha$ -particles, high-speed protons and neutrons.** M. C. HENDERSON (Physical Rev., 1934, [ii], 46, 324).

L. S. T.

**Measurement of very low relative humidities.** A. SIMONS (Proc. Physical Soc., 1936, 48, 135—144).—An apparatus for measuring dew points down to  $-40^\circ$ , corresponding with 0.5—10% R.H., and a hygrometer using wet and dry thermocouples are described. Calibration curves for the hygrometer for 0.5—10% R.H. and  $10$ — $90^\circ$  air temp. are given.

N. M. B.

**Automatic recording balance.** D. S. BINNINGTON and W. F. GEDDES (Ind. Eng. Chem. [Anal.], 1936, 8, 76—79).—The balance is electrically operated, fitted with oil damping, and counterbalanced for an initial load of 100 g. Wt. losses up to 17 g., with an accuracy of 0.01 g., are recorded without manual attention by an automatic device which places wts. on the pan. A continuous record is obtained on a paper chart by the use of a timed spark.

E. S. H.

**Micro-Dumas generation of carbon dioxide.** W. S. IDE (Ind. Eng. Chem. [Anal.], 1936, 8, 56).— $MgCO_3$  is introduced into the closed end of the micro-combustion tube. Before combustion, air is removed from the tube by heating the  $MgCO_3$ .

E. S. H.

**Check valve.** E. L. GREEN (Ind. Eng. Chem. [Anal.], 1936, 8, 40).—The device is designed to prevent the sucking back of liquids when passing a gas through them.

E. S. H.

**Ball mill.** L. L. QUILL (Ind. Eng. Chem. [Anal.], 1936, 8, 27).

E. S. H.

**Determination of the wall correction for the falling-sphere viscosimeter.** E. I. FULMER and J. C. WILLIAMS (J. Physical Chem., 1936, 40, 143—149).—Viscosity data have been obtained in the falling-sphere viscosimeter for castor oil, glycerol, solutions of colophony in turpentine, and two samples of honey. An equation has been derived giving the wall correction for vals. of  $r/R$  up to approx. 0.500.  $r$  and  $R$  are the radii of the sphere and the inside of the cylinder, respectively.

M. S. B.

**Surface tension by the ring method. Applicability of the Du Nouy apparatus.** R. MACY (J. Chem. Educ., 1935, 12, 573—576).—Methods by which data obtained by this method can be brought into line with those given in the International Critical Tables are described.

L. S. T.

**Practical application of lifting plate method to determination of surface tension.** W. DE KEYSER (Wis. nat. Tijds., 1934, 7, 107—118; Chem. Zentr., 1935, i, 3640—3641).—An expression is developed for the accurate determination of surface tension from the force required to lift a disc from the surface of a liquid.

J. S. A.

**Determination of surface tension of saturated aqueous solutions.** F. DE BLOCK (Wis. nat. Tijds., 1934, 7, 80—88; Chem. Zentr., 1935, i, 3641).—A lifting-disc method is applied to the determination of the surface tension of saturated solutions, and its dependence on temp.

J. S. A.

**Further applications of chemistry to archaeology.** W. FOSTER (J. Chem. Educ., 1935, 12, 577—579).—Ancient mortars and cements (Mayan), beeswax, and Pb are described.

L. S. T.

## Geochemistry.

**Temperature of atmospheric ozone.** J. DEVAUX (Compt. rend., 1935, 201, 1500—1501; cf. A., 1932, 108).—Infra-red spectra indicate a temp.  $< 0^\circ$ , which does not suffer appreciable diurnal or seasonal variation.

T. G. P.

**Penetration of solar and cosmic rays into fresh-water lakes.** G. A. LINHART (J. Physical Chem., 1936, 40, 113—119).—An equation previously deduced (Amer. Math. Month., 1935, 42, 224) is applied.

M. S. B.

**Origin of bore-hole water.** N. V. TAGEEVA (Nefit. Choz., 1934, 26, No. 7, 63—65).—Analyses are given. The  $H_2O$  originated from the ocean, and was later changed by contact with minerals.

CH. ABS. (e)

**Radium minerals.** V. CHARRIN (Rev. ind., 1935, 65, 19—20; Chem. Zentr., 1935, i, 3701).—A review of the occurrence and extraction of Ra. J. S. A.

**Occurrence of minerals in Hungary.** R. REICHERT (Foldtani Kozlony., 1934, 64, 348—356; Chem. Zentr., 1935, i, 3651).—Microscopic, chemical, and crystallographic data are given concerning Hungarian occurrences of marcasite, quartz in pyroxene andesite, hornblende and biotite, and phillipsite. J. S. A.

**Crystallographic data for Hungarian copper pyrites.** SZÁVA-KOVÁTS and K. RESCH (Foldtani Kozlony, 1934, 64, 334—341; Chem. Zentr., 1935, i, 3651).—Measurements on Cu pyrites from four sources are given. J. S. A.

**Granodiorite deposit of Štěnovic (near Pilsen) and its relation to neighbouring massifs.** A. ORLOV (Věst. stát. Geol. Ust. Česk. Repub., 1934, 10, 97—103; Chem. Zentr., 1935, i, 3651).—The oligoclase granodiorite of Štěnovic contains plagioclase (of oligoclase type, with zoned structure) 50%, quartz 20%, and orthoclase 10%, with amphibole and biotite. J. S. A.

**Chemical-mineralogical investigation of eruptive rocks of the central Sahara and the Sudan.** M. E. DENAEYER (Bull. Soc. franç. Min., 1934, 57, 284—337; Chem. Zentr., 1935, i, 3651).—A comprehensive résumé of chemical and mineralogical data. J. S. A.

**Bohmite and bayerite.** H. LEHL (J. Physical Chem., 1936, 40, 47—54).—Four definite crystalline forms of Al hydroxide are known. Diaspore gives  $\alpha$ -corundum on removal of  $H_2O$ . The other three forms, on losing  $H_2O$ , give cubic  $\gamma$ - $Al_2O_3$ . They are, in order of increasing stability, bohmite,  $Al_2O_3 \cdot H_2O$ , bayerite,  $Al_2O_3 \cdot 1.5H_2O$ , and gibbsite,  $Al_2O_3 \cdot 3H_2O$ . M. S. B.

**Helium content of minerals not emitting  $\alpha$ -rays and its explanation.** H. J. BORN (Naturwiss., 1936, 24, 73—76).—The origin of He in beryl and in alkali halides, particularly sylvine, is discussed. The He content of beryl is probably due to the action of  $\gamma$ -rays on  ${}^4Be^9$  giving  ${}^4Be^8$  and  ${}_0^1n$ , the  ${}^4Be^8$  breaking down to  ${}^2He^4$ . Sylvine and rock-salt often contain Pb, and the difference in He content of these minerals may depend on the concn. of U, Ra, and Ra-D in the  $H_2O$  from which they were originally deposited. Primary rock-salts contain only minute amounts of He. Those containing greater amounts have all been in contact with  $H_2O$  at some later period, and the high He content is connected with the high [Ra] in deep waters. A. J. M.

**Thermal decomposition of talc.** R. H. EWELL, E. N. BUNTING, and R. F. GELLER (J. Res. Nat. Bur. Stand., 1935, 15, 551—556).—Wt. losses and X-ray data are given. No change in crystal structure occurs up to 800°. At 800—840°, enstatite (I), amorphous

$SiO_2$ , and  $H_2O$  are formed. (I) forms clinoenstatite at 1200°, and amorphous  $SiO_2$  forms cristobalite at 1300°. H. J. E.

**Ejected blocks of the Laacher See district.** G. KALB (Tsch. Min. Petr. Mitt., 1936, 47, 185—210).—The sanidinites derived from crystalline schists are of two types: aegirine-augite-sanidinite (fenite) formed by pneumatolytic injection metamorphism with a phonolitic magma; and biotite-sanidinite formed by pneumatolytic contact metamorphism with an alkali-trachyte magma. L. J. S.

**Aphrosiderite from the granite of the Tatra Mts.** B. MAURITZ (Mat. Term. Ért., 1935, 53, 238—247, and Tsch. Min. Petr. Mitt., 1936, 47, 262—269).—Analysis of a chloritic mineral coating a block of granite identifies it with aphrosiderite. L. J. S.

**Yellow rock-salt from Hall in Tirol.** K. PRZIBRAM (Nature, 1936, 137, 107—108).—The discovery by Schaubberger of light-sensitive yellow rock-salt from this locality supplies the link, hitherto missing, in the formation of natural blue rock-salt. The absorption spectrum is the same as for rock-salt coloured artificially by Ra rays. The salt shows thermoluminescence, and on exposure to Ra rays it colours quickly; the artificial colour is likewise sensitive to light. L. S. T.

**Petrology of common volcanic rocks of Japan.** S. TSUBOI (Proc. V Pacific Sci. Congr., 1934, 3, 2271—2273).—The alkali-lime index for the Japanese volcanic rock series is 65.5. The compositions of pyroxenes are plotted. CH. ABS. (e)

**Chemical composition of the Deccan trap flows of Linga, Chhindwara District, Central Provinces.** L. L. FERMOR (Rec. Geol. Surv. India, 1934, 68, 344—360).—The minerals are described. Analyses are given. CH. ABS. (e)

**Occurrence of sphalerite at Ellsworth, Ohio.** G. U. GREENE (Amer. Min., 1935, 20, 882—883).—Sphalerite associated with barite or calcite is described. L. S. T.

**Morphology of phenacite from two new occurrences [at Klein-Spitzkopje, South West Africa, and the Morefield mine, Winterham, Amelia Co., Virginia].** F. H. POUGH (Amer. Min., 1935, 20, 863—874). L. S. T.

**Vectorial chemical alteration of crystals.** C. FRONDEL (Amer. Min., 1935, 20, 852—862).—Vectorial chemical alteration of crystals occurring in nature is described for pyrite (to hematite), enargite, stibnite (probably to wurtzite), and tourmaline. With barite and celestite, a partial overgrowth of a white opaque substance of later generation may simulate a vectorial alteration. Chemical changes in crystals may be affected by twinning, zoning in composition, and the physical nature of the bounding surface. Nucleation on crystal edges or surface imperfections is described for the topochemical alteration of azurite to malachite. L. S. T.

**Monticellite from San Bernardino County, California, and the monticellite series.** W. T. SCHALLER (Amer. Min., 1935, 20, 815—827).—Small

grains of monticellite (I) disseminated throughout a dolomite from the Dewey mine are the purest samples of (I) so far described. The FeO and MnO replacing MgO is < 1.50%.  $\alpha$  1.641,  $\beta$  1.649, and  $\gamma$  1.655 are < any other recorded vals. The components of the series  $\text{MgO}, \text{CaO}, \text{SiO}_2$  (I)— $\text{FeO}, \text{CaO}, \text{SiO}_2$ — $\text{MnO}, \text{CaO}, \text{SiO}_2$  (glaucochroite) are discussed and their refractive indices given. L. S. T.

**Experimental study of the porosity and permeability of clastic sediments.** H. J. FRASER (J. Geol., 1935, 43, 910—1010). L. S. T.

**Biotite system.** A. N. WINCHELL (Amer. Min., 1935, 20, 773—779).—A revision of data and diagrams (cf. A., 1925, ii, 592; 1926, 494). L. S. T.

**Occurrence and origin of celestite and fluorite at Clay Centre, Ohio.** R. B. MORRISON (Amer. Min., 1935, 20, 780—790).—Descriptive. L. S. T.

**Enargite and plumbojarosite at Picher, Oklahoma.** A. L. RANSOME (Amer. Min., 1935, 20, 799—805).—Crystals of enargite and plumbojarosite in a specimen from the Barr mine are described. L. S. T.

**Thulite in New Mexico.** S. A. NORTHPROP (Amer. Min., 1935, 20, 805—807).—Thulite,  $d$  3.15, occurs in quartz, associated with some actinolite, at Pilar Post Office, Taos Co., New Mexico. An analysis is given. L. S. T.

**Quartz paramorphs after tridymite and cristobalite.** R. S. MOEHLMAN (Amer. Min., 1935, 20, 808—810).—Abnormal forms of quartz, probably the result of inversion from tridymite and cristobalite, have been observed in Miocene volcanic rocks southwest of Ouray, Colorado. L. S. T.

**Composition of asbestos and other fibres of Thetford district, Quebec.** H. C. COOKE (Trans. Roy. Soc. Canada, 1935, [iii], 29, IV, 7—19).—Several analyses are given of carefully selected chrysotile of different degrees of softness and harshness, and these are interpreted as mixtures of serpentine ( $\text{H}_4\text{Mg}_3\text{Si}_2\text{O}_9$ ), chlorite, talc, brucite, periclase, etc. Harshness seems to be connected with excess of  $\text{SiO}_2$  and the presence of more talc and periclase and less  $\text{H}_2\text{O}$ . Analyses of fibrous materials occurring on slickensided surfaces and in faults show that these may range from serpentine to brucite. L. J. S.

**Manganese concretions in Nova Scotia lakes.** E. M. KINDLE (Trans. Roy. Soc. Canada, 1935, [iii], 29, IV, 163—180).—The nodular or more often disc- or saucer-shaped concretions (3—6 in. across) are formed around pebbles on the bottom of the lakes, and contain  $\text{MnO}_2$  35.29,  $\text{Fe}_2\text{O}_3$  16.56%. They have probably been formed by the action of algae extracting Mn and Fe from the lake water. L. J. S.

**Role of manganese in minerals.** H. OTTO (Tsch. Min. Petr. Mitt., 1935, 47, 89—140).—Several new chemical analyses together with optical data are given of various manganese-bearing minerals (phosphates and silicates), and the results are plotted, together with data from the lit., showing a decrease in  $n$  with isomorphous replacement of  $\text{Fe}^{II}$  by  $\text{Mn}^{II}$  and an increase with replacement of Zn, Mg, Li,

Ca by  $\text{Mn}^{II}$  and of Al by  $\text{Mn}^{III}$ . The varied coloration of Mn minerals and the occurrence of Mn in different kinds of rocks are discussed. L. J. S.

**Pyrometasomatic vein deposits at Tepezala, Aguascalientes, Mexico.** A. WANDKE and T. G. MOORE (Econ. Geol., 1935, 30, 765—782).—The rock types and ore deposits are described. CaO-silicate minerals occur both as products of wall rock alteration and as gangue minerals in the veins proper. The sulphide ore, chiefly chalcopyrite with minor amounts of pyrite, sphalerite, and galena, is associated with abundant diopside (I), hedenbergite (II), garnet, epidote (III), fluorite, quartz (IV), etc. as vein gangue minerals. The marginal alteration associated with the veins consists of an intergrowth of (I), (II), (III), and (IV). This alteration affects both intruded and intrusive rock and is probably the first work of the solutions as they rose in the fractures. The sequence of mineral deposition is discussed, and a comparison with other pyrometasomatic districts is made. The deposits are considered to be of Tertiary age. L. S. T.

**Iron ore deposits of the Ilmpeia River, Eastern Siberia.** V. SOBOLEV (Econ. Geol., 1935, 30, 783—791).—The geology and petrology of the district are briefly discussed. The Fe ore deposits, which present a new instance of a special type of magnetite deposits, are described and analyses are given. Their origin also is discussed. L. S. T.

**Kaldurga conglomerates and the iron ore series of the Bababudans, Kadur district, Mysore.** (A) M. B. R. RAO. (B) C. S. PICHAMUTHU (Current Sci., 1935, 4, 415—417, 417—418).—(A) A criticism of Pichamuthu (cf. A., 1935, 1479). (B) A reply. N. M. B.

**Some deposits of lead ores in the state of Minas Geraes.** B. A. WENDEBORN (Bol. Min. Agric. [Brazil], 1935, 24, 35—77).—The geology of the region studied (a zone of 1100 km. from Sete Lagoas through Pirapora to Montes Claros, and about 10—20 km. wide) is described with especial reference to, and analyses of, the Pb ores found. E. L.

**Lead-bismuth ores in Bleka, Svartdal, Norway.** C. BUGGE (Econ. Geol., 1935, 30, 792—799).—The ore (analyses given) occurring at Bleka in quartz (I) veins in a gabbro dyke is mainly galenobismutite with small amounts of bismutite ( $\text{Bi}_2\text{S}_3$ ) and traces of galena. Emplectite has also been found. Au-bearing veins also occur and the gangue consists of dominant (I), barite, brown spar, tourmaline, and traces of fluor spar. Chalcopyrite is also important. L. S. T.

**Spectrographic evidence on origin of ores of Mississippi Valley type.** L. C. GRATON and G. A. HARCOURT (Econ. Geol., 1935, 30, 800—824).—Spectrographic examination shows that sphalerites from many deposits of the so-called Mississippi Valley type appear to contain amounts of Fe, Cu, and Pb, and of the less common elements, especially Cd, Ga, Ge, and In, commensurate with those found in deposits formed by solutions of magmatic origin. The geochemistry of the latter group of elements

in this connexion is discussed. A definite and systematic serial relationship between these sphalerites and those of hydrothermal sphalerites of a magmatic group is indicated. L. S. T.

**Steigerite, a new vanadium mineral.** E. P. HENDERSON (Amer. Min., 1935, 20, 769—772).—Steigerite (I),  $\text{Al}_2\text{O}_3 \cdot \text{V}_2\text{O}_5 \cdot 6.5\text{H}_2\text{O}$ , similar to fervanite (II), has been found in the U-V deposits of the Gypsum Valley, San Miguel Co., Colorado. (I),  $n$  1.71  $\pm$  0.005, has  $\text{V}_2\text{O}_5$  44.44,  $\text{Al}_2\text{O}_3$  25.14,  $\text{Fe}_2\text{O}_3$  1.50,  $\text{H}_2\text{O}$ —8.08,  $\text{H}_2\text{O} +$  21.04, total 100.20%. It is bright canary-yellow in colour, insol. in  $\text{H}_2\text{O}$ , and is easily decomposed by mineral acids. X-Ray examination shows that (I) is cryst. giving a pattern different from that of (II). L. S. T.

**Pegmatite minerals from near Amelia, Virginia.** J. J. GLASS (Amer. Min., 1935, 20, 741—768).—31 mineral species have been identified from the pegmatites of Amelia and eight of these, viz., bertrandite, biotite, chalcopyrite, phenacite, pyro-lusite, topaz, triplite, and zinnwaldite, are described in detail for the first time. The physical and optical properties of the two varieties of microlite which occur are compared, and several varieties of sericite (with analyses) are described. The zinnwaldite has  $\text{SiO}_2$  43.70,  $\text{Al}_2\text{O}_3$  22.96,  $\text{Fe}_2\text{O}_3$  0.59,  $\text{FeO}$  11.67,  $\text{TiO}_2$  0.32,  $\text{MgO}$  0.03,  $\text{CaO}$  0.02,  $\text{Na}_2\text{O}$  0.74,  $\text{K}_2\text{O}$  9.58,  $\text{H}_2\text{O}$ —0.08,  $\text{H}_2\text{O} +$  1.35,  $\text{MnO}$  1.95,  $\text{F}$  5.52,  $\text{Li}_2\text{O}$  1.92,  $\text{Rb}_2\text{O}$  1.04,  $\text{Cs}_2\text{O}$  0.10, total 101.58, (less O 2.32) 99.26%. New optical determinations and other properties of nearly all the minerals which occur at Amelia are tabulated. The less common elements, identified by spectrographic analyses in many of these minerals, are recorded. L. S. T.

**Lithology of the precipitation of "domanic" shales from the upper Devonian of the western**

**slope of the Ural mountains.** A. A. VAROV (Nef't Choz., 1934, 26, No. 7, 32—37).—The shales contain  $\text{TiO}_2$  0.2–0.3,  $\text{Mn} > 2.23$ ,  $\text{Fe}_2\text{O}_3 > 2$ , total S 2—3,  $\text{SO}_4^{2-}$  0.2—0.3%. The  $\text{P}_2\text{O}_5$  (0.1—0.5%) is higher in the carbonate shales than in the siliceous shales. CH. ABS. (e)

**Lithology of the clay facies of the carboniferous in the Samara U-bend of the Volga river.** L. A. GULJAEVA (Nef't. Choz., 1934, 26, No. 7, 26—31).—The clay from various depths ( $> 1000$  m) contained alkalis 6—10,  $\text{CO}_2 < 6$ ,  $\text{Mg}$  1—3%. It was low in Mn, Cl, and  $\text{H}_2\text{SO}_4$ . CH. ABS. (e)

**Enrichment of titania in clays.** A. SALMINEN (Suomen Kem., 1936, 9, A, 1—4).—The average  $\text{TiO}_2$  content of 27 Finnish clays was 0.68%; that of 12 sands was 0.40%. S. M. N.

**Geological aspects of recent research on coal.**—See B., 1936, 82.

**Geology and presence of petroleum in northern Ferghana.** G. I. SCHATOV (Nef't. Choz., 1934, 26, No. 10, 21—22). CH. ABS. (e)

**Geological characterisation of the Tschikischlyar oil-bearing district in Turkmenia.** A. I. KOSUIGN (Nef't. Choz., 1934, 26, No. 7, 49—55).—Analytical data are given for various volcanic, and other, gas and oil producers, on the east shore of the Caspian Sea. CH. ABS. (e)

**Athabasca oil sands: apparent example of local origin of oil.** M. W. BALL (Bull. Amer. Assoc. Pet. Geol., 1935, 19, 153—171).—The oil occurs as a film around each grain of sand. It is of asphaltic base, very heavy, high in S, and is readily cracked at  $<$  the normal temp., yielding 20—35% of gasoline. It is probably a young oil, which has not been geologically cracked. CH. ABS. (e)

## Organic Chemistry

**Comparison and critical analysis of physical properties of homologues and isomerides. Molecular volume of alkanes.** G. CALINGAERT and J. H. HLADKY (J. Amer. Chem. Soc., 1936, 58, 153—161).—A series of parallel curves is obtained by plotting  $\log V$  against no. of C atoms in the longest chain;  $n$  on a rare scale is used. Certain irregularities and the need of new data are discussed. H. B.

**Combustion of hydrocarbons I, II.**—See this vol., 294.

**Occurrence of radicals in the thermal decomposition of molecules and the reaction  $\text{CH}_3 + \text{H}_2$ .**—See this vol., 293.

**Formation of condensation products from simple hydrocarbons.** M. W. TRAVERS (Trans. Faraday Soc., 1936, 32, 236—246).—Work previously (A., 1935, 40) on the pyrolysis of  $\text{C}_2\text{H}_6$  and condensation of  $\text{C}_2\text{H}_4$  is reviewed. In presence of  $\text{H}_2$  at  $50^\circ$   $\text{CHMe} \cdot \text{CH}_2$  yields  $\text{C}_2\text{H}_4$  and  $\text{CH}_4$ , whilst at the same time condensation proceeds from initial reactions  $2\text{C}_3\text{H}_6 = (\text{C}_3\text{H}_6)_2$  and  $\text{C}_3\text{H}_6 + \text{C}_2\text{H}_4 = \text{C}_5\text{H}_{10}$ . Preliminary experiments with  $\text{C}_2\text{H}_2$  indicate

that the state of the  $\text{SiO}_2$ -glass surface influences the nature of the reaction. F. L. U.

**Development of the intermolecular and intramolecular chains in oxidation of  $n$ -hexane.** W. M. ZAIKOVSKY (Physical Rev., 1934, [ii], 46, 329). Analytical data of the oxidised air- $n$ -hexane mixture are discussed. L. S. T.

**Isomerisation of  $n$ -heptane.** G. CALINGAERT and H. A. BEATTY (J. Amer. Chem. Soc., 1936, 58, 51—54; cf. A., 1935, 843).— $n\text{-C}_7\text{H}_{16}$  heated with  $\text{AlCl}_3$  gives pentanes (+lower hydrocarbons) 64.6% (of  $\text{C}_7\text{H}_{16}$  reacting),  $\beta$ - and  $\gamma$ -methylpentane 3.4 and 2%, respectively,  $n\text{-C}_6\text{H}_{14}$  0.4%,  $\beta\delta$ -dimethylpentane 1.5%,  $\beta\gamma$ -trimethylbutane 0.5%,  $\gamma\gamma$ -dimethylpentane 0.4%,  $\beta$ - and  $\gamma$ -methylhexane 1.2 and 1.6%, respectively, and polymerisation products 24.4%. The above % are deduced from vals. of  $n$ , b.p., and crit. solution temp. in  $\text{NH}_2\text{Ph}$ . H. B.

**Highly polymerised compounds. [Viscosity of solutions of aliphatic hydrocarbons.]** H. STAUDINGER (Ber., 1936, 69, [B], 203—208).—A reply to Meyer *et al.* (A., 1935, 1318). H. W.

**Paraffin hydrocarbon from urine of pregnancy.**—See this vol., 362.

**Mechanism of addition of halogens to ethylenic linkings.** R. A. Ogg, jun. (J. Amer. Chem. Soc., 1935, 57, 2727—2728).—The following mechanism, which applies to reactions in solution and in the dark, is suggested:  $\text{CHR}:\text{CHR} + \text{Br}^- \rightarrow \text{CHRBr}:\text{CHR}^-$   $\xrightarrow{\text{Br-Br}}$   $\text{CHRBr}:\text{CHRBr} + \text{Br}^-$ . Addition is thus catalysed by  $\text{Br}^-$ ; evidence (lit.) supporting this view is given. Since the intermediate carbanion has a stable configuration, stereoisomerides should be formed from *cis*- and *trans*-isomerides; the theories of Carothers (A., 1924, ii, 814) and Ingold (Chem. Reviews, 1934, 15, 225) lead to identical additive products. The above theory also explains the generally observed *trans* addition of Hal. H. B.

**Mechanism of polymerisation.**—See this vol., 295.

**Polymerides and polyfunctionality.**—See this vol., 295.

**Formation of high polymerides of unsaturated substances.**—See this vol., 295.

**Polymerisation of unsaturated hydrocarbons.** H. I. WATERMAN and J. J. LEENDERTSE (Trans. Faraday Soc., 1936, 32, 251—257; cf. A., 1935, 480).—A review of work previously published.

F. L. U.

**Peroxide effect in addition of reagents to unsaturated compounds. XI. Solvent effect in addition of hydrogen bromide to isobutene.** M. S. KHARASCH and W. M. POTTS (J. Amer. Chem. Soc., 1936, 58, 57—59; cf. A., 1934, 792).—Addition of HBr to isobutene in a vac. in presence of antioxidants and solvents (pentane,  $\text{CS}_2$ ,  $\text{EtCO}_2\text{H}$ ,  $\text{EtBr}$ ,  $\text{PhCN}$ ,  $\text{PhNO}_2$ ,  $\text{H}_2\text{O}$ ) gives 80—92% yields of  $\text{Bu}^\gamma\text{Br}$ . In presence of ascaridole (0.03—0.04 mol.) and the same solvents a mixture of  $\text{Bu}^\beta\text{Br}$  (75—87% except in  $\text{CS}_2$  when 100%) and  $\text{Bu}^\gamma\text{Br}$  (13—25%) results. The data now obtained confirm the conclusion (*loc. cit.*) that solvents affect the velocity, but not the direction, of addition. H. B.

**Photoiodination of ethylenic linking at low temperatures.** G. S. FORBES and A. F. NELSON (J. Amer. Chem. Soc., 1936, 58, 182—183).—Illumination (through 10 cm.  $\text{H}_2\text{O}$ ) of an equimol. mixture of  $\Delta^a$ -butene (0.01M in  $\text{CHCl}_3$ ) and I at  $-70^\circ$  to  $-60^\circ$  with light from incandescence lamps causes 98% disappearance of I after 3 hr. (90% in  $\text{CH}_2\text{Cl}_2$  at  $90^\circ$  to  $-60^\circ$ ); I does not react with the solvent. Subsequent exposure of the solution in quartz to light from a W-steel spark causes quant. elimination of the I within 1 hr.; when the solution is kept at  $20^\circ/100$  hr., 84% elimination of I occurs. H. B.

**Dibromide method of determination of butene mixtures.** W. G. YOUNG and S. WINSTEIN (J. Amer. Chem. Soc., 1936, 58, 102—104).—Contrary to Pines (A., 1933, 1138) and Komarewsky *et al.* (A., 1935, 192), the reaction rate-dibromide method (A. 1930, 888) is trustworthy. Conversion of mixtures into dibromides (composition not altered by distillation at atm. pressure) does not cause an appreciable change in composition. Differences in composition

of the  $\text{C}_4\text{H}_8$  prepared by catalytic decomp. of  $\text{Bu}^\alpha\text{OH}$  are ascribed to the effects of catalyst and temp. rather than to analytical procedure. H. B.

**Application of the structure theory of reactions to Lebedev's synthesis of butadiene from alcohol and to Rice's theory of pyrolysis.**—See this vol., 167.

**Polymerisation of  $\Delta^a$ -butadiene in presence of metallic sodium.**—See this vol., 296.

**Induced substitution of pentene by chlorine.** T. D. STEWART and B. WEIDENBAUM (J. Amer. Chem. Soc., 1936, 58, 98—100).—The following reactions occur between  $\Delta^a$ -pentene and  $\text{Cl}_2$  in  $\text{CCl}_4$  at  $-10$  or  $25.1^\circ$ :  $\text{CH}(\text{Et}):\text{CHMe} + \text{Cl}_2 \rightarrow \text{CH}(\text{Et})\text{Cl}:\text{CHMeCl}$ ;  $\text{CH}(\text{Et}):\text{CHMe} + \text{Cl}_2 \rightarrow \text{CH}(\text{Et})\text{CH}:\text{CH}_2\text{Cl}$  (I) + HCl. Substitution is favoured by decreasing the  $[\text{Cl}_2]$ ; addition of  $\text{H}_2\text{O}$ , HCl, or powdered glass has no effect. Substitution also occurs, but to a smaller extent, with  $\text{CH}_2:\text{CH}:\text{CH}_2\text{Ph}$  but not with  $\text{CH}_2:\text{CMeCl}$  (II). A reaction mechanism is discussed. The pseudo-unimol. velocity coeffs. (mols. per litre at  $25^\circ$ ) of quaternary salt formation between  $\text{NMe}_3$  (ten-fold excess) and (I),  $\text{CH}_2:\text{CH}:\text{CH}_2\text{Cl}$  (II), and  $\text{CCl}_4$  are 0.109, 0.045, 0, and 0, respectively. H. B.

**Dicrotyl [ $\Delta^a$ -octadiene].** R. LESPIEAU and P. HEITZMANN (Bull. Soc. chim., 1936, [v], 3, 273—277).— $\text{CHMe}:\text{CH}:\text{CH}_2\text{MgBr}$  and  $\text{H}_2\text{O}$  give a mixture of dicrotyls [ $\Delta^a$ -octadienes], b.p.  $122$ — $125^\circ$  [does not add I; hydrogenated to  $n\text{-C}_8\text{H}_{18}$ ; oxidised to  $\text{AcOH}$  and  $(-\text{CH}_2\text{CO}_2\text{H})_2$ ], *trans-trans-dicrotyl*, b.p.  $124^\circ/747$  mm., m.p. about  $-76^\circ$  (*tetra-bromide*, m.p.  $84$ — $84.5^\circ$ , and *-iodide*, decomp. about  $100^\circ$ ), and *trans- $\gamma$ -methyl- $\Delta^a$ -heptadiene*, b.p.  $115^\circ$ , m.p. about  $-57^\circ$  (*di-iodide*, m.p.  $155$ — $156^\circ$ ; oxidised to  $\text{H}_2\text{C}_2\text{O}_4$  and  $\text{CO}_2\text{H}:\text{CH}_2:\text{CHMe}:\text{CO}_2\text{H}$ ; hydrogenated to  $\gamma$ -methylheptane, b.p.  $118.5^\circ$ ). R. S. C.

**Mercury-photosensitised polymerisation of acetylene.**—See this vol., 299.

**Peroxide effect in addition of reagents to unsaturated compounds. X. Addition of hydrogen bromide to methylacetylene (allylene).** M. S. KHARASCH, J. G. McNAB, and M. C. McNAB (J. Amer. Chem. Soc., 1935, 57, 2463—2465).—“Normal addition (in a vac. in absence or presence of antioxidant) of HBr to  $\text{CH}_3\text{CMe}$  (I) gives  $\text{CMe}_2\text{Br}_2$ . In presence of ascaridole (II),  $\text{CHMeBr}:\text{CH}_2\text{Br}$  is formed; the HBr must be passed into the (I)+(II) at  $-40^\circ$  to  $-33^\circ$ . (I) is not very sensitive to  $\text{O}_2$ . H. B.

**Divinylacetylene and its derivatives.** P. V. SHAVERONKOV, A. P. ALECHINA, and R. S. SCHTER (Sintet. Kautschuk, 1934, No. 2, 12—14; cf. A., 1933, 694).—Divinylacetylene (I), b.p.  $46$ — $47^\circ/200$  mm., obtained as a by-product in the prep. of chloroprene from  $\text{C}_2\text{H}_2$ , polymerises in 7—8 days in air to a gel which explodes on drying and cannot be used in the production of protective films. Antioxidants retard the formation of explosive films, whilst chlorination gives “safety” films. (I) yields *vinyl allyl ketone*, b.p.  $85$ — $86^\circ/20$  mm., by the addition of  $\text{H}_2\text{O}$ .

CH. ABS. (r)

**Reaction of butylacetylene with oxygen.** C. . . YOUNG, R. R. VOGT, and J. A. NIEUWLAND (J. Amer. Chem. Soc., 1936, 58, 55—56; cf. A., 1935, 325).—

CH<sub>3</sub>CBu, freed from olefine by regeneration from CBr<sub>4</sub>:C<sub>6</sub>H<sub>5</sub>AgNO<sub>3</sub> with aq. NaCN, forms a peroxide (attempted isolation by distillation caused decomp.); when kept in O<sub>2</sub> at 35–45°/3 months, valeric acid (8 g. from 123 g.) and polymeric material are produced.

H. B.

**Catalytic dechlorination of tetrachloroethane.** I. Decomposition by active carbon. II. Order of the decomposition reaction of tetrachloroethane. S. YAMAGUCHI (J. Chem. Soc. Japan, 1934, 55, 1227–1231, 1232–1235).—I. The effect of temp. and of various added materials is described.

II. The reaction  $2C_2H_2Cl_4 \xrightarrow{C} 2C_2H_2Cl_2 + HCl$  is of the second order in the presence of active C.

CH. ABS. (r)

**Constitution of the  $\alpha\beta$ -halogen derivatives of ethane.**—See this vol., 269.

**Allylic rearrangements.** I. Crotyl and methylvinylcarbinyl bromides. S. WINSTEIN and W. G. YOUNG (J. Amer. Chem. Soc., 1936, 58, 104–107).—Largely a more detailed account of work previously reviewed (A., 1935, 1480). Mixtures of CHMe:CH:CH<sub>2</sub>Br, b.p. 2°/5 mm., and CH<sub>3</sub>:CH:CHMeBr (I), b.p. –2°/14 mm., 31°/93 mm., are separated by fractional distillation at low temp. in a vac.; higher temp. cause rearrangement. Slow distillation/atm. pressure of a mixture [13% (I)] gives a product containing 87.5% of (I) (cf. loc. cit.).

H. B.

**Mechanism of the catalytic conversion of alcohols into diethylene hydrocarbons.** S. V. LEBEDEV, J. A. GORIN, and S. N. CHUTORETZKAJA (Sintet. Kautschuk, 1935, 4, No. 1, 8–27).—Catalytic decomp. of a mixture of EtOH and MeCHO affords butadiene (I). The influence of varying conditions on the yield of (I) is described. Catalytic decomp. of a mixture of EtOH and Et<sub>2</sub>O yields (I), together with C<sub>2</sub>H<sub>4</sub> and (CHMe)<sub>2</sub>, the proportions depending on the conditions. Mixtures of EtOH with H<sub>2</sub>O, H<sub>2</sub>, and BuOH behave similarly; the influence of varying conditions on the yield of (I) is described.

CH. ABS. (r)

containing  $\beta\gamma$ -dimethyl- $\Delta^{\beta}$ -butene (about 70%)  $\gamma\gamma$ -dimethyl- $\Delta^{\alpha}$ -butene (about 3%), and  $\beta\gamma$ -dimethyl- $\Delta^{\alpha}$ -butene (about 27%). The formation of a radical and its immediate isomerisation,  $CH_3\cdot C^*\cdot CMe_2 \rightarrow CH_2\cdot CMe_2\cdot C^*\cdot Me$ ,  $C^*\cdot H_2\cdot CMe_2\cdot CMe_2$ , is assumed, hydrogenation at the expense of Bu<sup>2</sup> occurring at C\* atoms. The dehydration of methyltert.-butylcarbinol is explained similarly.

H. W.

**Fission and isomerisation of olefines which contain a tertiary radical.** I. N. NASAROV (Ber. 1936, 69, [B], 21–24).—Methylisopropyltert.-butylcarbinol (I) is transformed by distillation with a trace of I into  $\gamma$ -methylene- $\beta\beta\delta$ -trimethylpentane smoothly transformed by 1:4-C<sub>10</sub>H<sub>6</sub>Br·SO<sub>3</sub>H into  $\beta$ -methyl- $\Delta^{\alpha}$ -propene and  $\beta$ -methyl- $\Delta^{\beta}$ -butene, also obtained directly from (I). Ethylisopropyltert.-butylcarbinol, b.p. 188–191°, is dehydrated by I to  $\delta\delta$ -dimethyl- $\gamma$ -isopropyl- $\Delta^{\beta}$ -butene, b.p. 153–158°, which is transformed by 1:4-C<sub>10</sub>H<sub>6</sub>Br·SO<sub>3</sub>H into  $\beta$ -methyl- $\Delta$ -propene and, apparently,  $\beta$ -methyl- $\Delta^{\beta}$ -pentene and  $\beta$ -methyl- $\Delta^{\alpha}$ -pentene.

H. W.

**Pyrolysis of geraniol and citral.** J. DÈUVRE and R. DESMULE (Bull. Soc. chim., 1936, [v], 3, 196–206).—In presence of Pt or glass wool at 505–510° geraniol (p-xenylurethane, m.p. 69°) gives much isoprene and CMe<sub>2</sub>:CH:CHO [semicarbazone, m.p. 240° (block)]; p-nitro-, m.p. 161°, and 2:4-dinitro-phenylhydrazones, m.p. 187–188°, with CH<sub>3</sub>O, MeCHO. CHMe:CH:CO<sub>2</sub>H, (?) CMe<sub>2</sub>:CH:CH<sub>2</sub>:OH, and a mixture of (? $\beta\eta$ - and  $\beta\zeta$ -)dimethyl- $\Delta^{\beta\delta}$ -octadienes, b.p. 67–68°/20 mm., all of which arise by fission of the  $\delta\epsilon$ -linking or formation and fission of an internal  $\gamma$ -oxide. Citral gives much CH<sub>3</sub>:CHMe and other gases with a complex mixture containing  $\beta\zeta$ -dimethyl- $\Delta^{\alpha}$ -nonadiene, b.p. 141–143° (corr.)/750 mm., a hydrocarbon, C<sub>10</sub>H<sub>18</sub>, b.p. 66°/19 mm., a little isoprene, and a trace of CMe<sub>2</sub>:CH:CHO.

R. S. C.

(A) Hexadecenol and tetradecenol in sperm head oil. Y. TOYAMA and T. TSUCHIYA. (B) Hexadecenol in sperm blubber oil. Y. TOYAMA and G. AKIYAMA (Bull. Chem. Soc. Japan, 1935, 10, 572–579, 579–584).—(A) Fractionation of the Ac derivatives of the unsaponifiable matter, b.p. < 180°/15 mm., of sperm head oil, conversion of the unsaturated acetates into their bromides, debromination, and refractionation of the unsaturated acetates affords the Ac derivative, b.p. 195–198°/15 mm. (oxidised by KMnO<sub>4</sub>-AcOH to *n*-C<sub>6</sub>H<sub>13</sub>·CO<sub>2</sub>H and OAc[CH<sub>2</sub>]<sub>8</sub>·CO<sub>2</sub>H), of  $\Delta^1$ -hexadecen- $\alpha$ -ol (I) (zoomaryl alcohol), I val. 98.6, and the Ac derivative, b.p. 165–170°/15 mm. (oxidised to *n*-C<sub>8</sub>H<sub>17</sub>·CO<sub>2</sub>H and  $\gamma$ -hydroxyvaleric acid), of  $\Delta^1$ -tetradecen- $\alpha$ -ol (physeteryl alcohol), I val. 111.2.

(B) The isolation (by similar methods) of (I) (16 g.) from the unsaponifiable portion (10 kg.; 36.1% of the oil) of sperm blubber oil, is described. J. W. B.

**Lipins of tubercle bacilli.** XLI. 1. Composition of timothy bacillus wax. 2. Isolation of  $\alpha$ -eicosan- $\beta$ -ol and  $\alpha$ -octadecan- $\beta$ -ol from the unsaponifiable matter of timothy bacillus wax. M. C. PANGBORN and R. J. ANDERSON (J. Amer. Chem. Soc., 1936, 58, 10–14).—The wax (A., 1931, 526), purified by repeated pptn. from Et<sub>2</sub>O with

**Action of sulphuric acid on sec.-butyl alcohol.** N. L. DRAKE and F. P. VEITCH, jun. (J. Amer. Chem. Soc., 1935, 57, 2623–2625).—sec.-BuOH and 75% H<sub>2</sub>SO<sub>4</sub> at 80°/48 hr. under pressure give a mixture of (sec.-Bu)<sub>2</sub>O and  $\gamma\delta$ -dimethyl- $\Delta^{\beta}$ -hexene (I) [ozonolysis products, MeCHO, AcOH, and Me sec.-Bu ketone (II) (2:4-dinitrophenylhydrazones, m.p. 71.2°)]. Distillation of (I) with a trace of acid gives substances of higher mol. wt. (II) is oxidised (NaOBr) to  $\alpha$ -methylbutyric acid (p-phenylphenacyl ester, m.p. 70.6°). Whitmore's mechanism of polymerisation by acids explains the production of (I) better than that of Kline and Drake (A., 1935, 192).

H. B.

**Dehydration of methyltert.-butylcarbinol.** Fission and isomerisation of ditert.-butylethylene. I. N. NASAROV (Ber., 1936, 69, [B], 18–21; cf. Whitmore et al., A., 1933, 1140).—Distillation of methyltert.-butylcarbinol with I affords essentially  $\gamma$ -methylene- $\beta\beta\delta$ -tetramethylpentane, which readily suffers fission when heated with 1:4-C<sub>10</sub>H<sub>6</sub>Br·SO<sub>3</sub>H into  $\beta$ -methyl- $\Delta^{\alpha}$ -propene and a liquid mixture

COMe., has m.p. 45°, I val. 20.5, sap. val. 66.9,  $[\alpha]_D +10.1^\circ$  in  $\text{CHCl}_3$ . Hydrolysis (5% EtOH-KOH in  $\text{N}_2$ ) gives glycerol, trehalose, optically active higher fatty acids, and a dibasic OH-acid,  $\text{C}_{70}\text{H}_{138}\text{O}_6$ , m.p. 56–57°,  $[\alpha]_D +6.1^\circ$  in  $\text{CHCl}_3$  [Ac derivative, m.p. 40–41°; Me ester, m.p. 49° (Ac derivative, m.p. 41°)]. The unsaponifiable matter consists almost entirely of higher alcohols since treatment with  $\alpha\text{-C}_6\text{H}_4(\text{CO})_2\text{O}$  gives nearly quant. conversion into H phthalates. Fractional crystallisation of the alcohols (from MeOH) and their phenylcarbamates affords d-eicosan- $\beta$ -ol (I), m.p. 62.5–63°,  $[\alpha]_D +4.2$  in  $\text{CHCl}_3$  (acetate, m.p. 35–37°; benzoate, m.p. 39–40°; m.p. 78–78.5°, solidifies at 76° and remelts at 81°;  $\bar{H}$  m.p. 60–61), and d-octadecan- $\beta$ -ol (II), m.p. 56°,  $[\alpha]_D +5.7$  in  $\text{CHCl}_3$  (phenylcarbamate, m.p. 72–73°, solidifies at 66° and remelts at 76–77°). (I) is oxidised ( $\text{CrO}_3\text{-AcOH}$ , 30–40°) to eicosan- $\beta$ -one, m.p. 58–59° (oxime, m.p. 73–74°; semicarbazone, m.p. 128°), which is also prepared by alkaline hydrolysis of the product from n-heptadecyl bromide and  $\text{CHNaAc}\cdot\text{CO}_2\text{Et}$ . (II) is similarly oxidised to octadecan- $\beta$ -one, m.p. 52° (semicarbazone, m.p. 127.5°), also synthesised from n-heptadecoyl chloride and  $\text{ZnMeI}$ . H. B.

**Stability of pinacolates in liquid ammonia solution.** C. B. WOOSTER and D. S. LATHAM (J. Amer. Chem. Soc., 1936, 58, 76–78).— $(\text{CMe}_2\cdot\text{OH})_2$  (I) and  $(\text{CPhMe}\cdot\text{OH})_2$  (II) with  $\text{NaNH}_2$  (or  $\text{CNaPh}_2$ ) in liquid  $\text{NH}_3$  give the colourless  $(\text{CRMe}\cdot\text{ONa})_2$ , which are hydrolysed ( $\text{NH}_4\text{Cl}$ ) to the pinacols but no  $\text{CORMe}$ ; ketyl formation [as with  $(\text{CPh}_2\cdot\text{OH})_2$  (cf. Kraus and Bien, A., 1933, 1120)] does not occur. (I) and (II) can be titrated with  $\text{NaNH}_2$  using  $\text{CHPh}_3$  as indicator. (I) and Na in liquid  $\text{NH}_3$  give  $\text{OH}\cdot\text{CMe}_2\cdot\text{CMe}_2\cdot\text{ONa}$ ; (II) undergoes fission to  $\text{CHPhMe}\cdot\text{ONa}$ . Hydrobenzoin is too insol. in liquid  $\text{NH}_3$  to react with  $\text{NaNH}_2$ . H. B.

**Compounds of bivalent carbon.** XIV. Bromodimethoxymethane (formyl bromide dimethyl acetal) and its reaction with sodium triphenylmethyl. H. SCHEIBLER and H. J. SCHMIDT (Ber., 1936, 69, [B], 12–15; cf. this vol., 66).— $(\text{OMe})_2\text{CH}\cdot\text{CO}_2\text{H}$  is readily converted by Br in warm  $\text{CHCl}_3$  in direct sunlight into bromodimethoxymethane (I) b.p. 55°/12 mm., and Me H oxalate, b.p. 75°/12 mm. (K salt). (I) and  $\text{CNaPh}_3$  in  $\text{Et}_2\text{O}$  under  $\text{N}_2$  yield the unstable triphenylacetaldehyde Me., acetal, which immediately decomposes into  $\text{CHPh}_3$  and (not-isolated) dimethoxymethylene ( $\text{CO Me}_2$  acetal). H. W.

**Small-scale experiments on the autoxidation of ether.** A. RIECHE and R. MEISTER (Angew. Chem., 1936, 49, 101–103).— $\text{PhCHO}$  treated with  $\text{H}_2\text{O}_2$ , followed by  $\text{CH}_2\text{Ph}\cdot\text{OH}$  and  $\text{P}_2\text{O}_5$ , yields dibenzyl ether peroxide,  $(\text{CH}_2\text{Ph}\cdot\text{O})_2$ , m.p. 11°.  $\text{OH}\cdot\text{CHMe}\cdot\text{O}\cdot\text{H}$  (I) dehydrated with  $\text{P}_2\text{O}_5$  in  $\text{Me}_2\text{O}$  at low temp. yields the compound  $(\text{CHMe}\cdot\text{O}\cdot\text{H})_2\text{O}$ . (I) treated with  $\text{MeCHO}$  and  $\text{H}_2\text{O}_2$  in  $\text{Et}_2\text{O}$  at 20°, the mixture cooled in  $\text{Et}_2\text{O}$ -solid  $\text{CO}_2$ , and MeCl added followed by  $\text{P}_2\text{O}_5$  yields  $\alpha$ -ethoxyethyl H peroxide, which under appropriate conditions of decomp. gives EtOH, MeCHO, AcOH,  $\text{H}_2\text{O}_2$ , and polymerised

ethylidene peroxide. A complete mechanism for the autoxidation of  $\text{Et}_2\text{O}$  is suggested. T. G. P.

**Preparation of ketals of alkylacetylenes with higher alcohols.** D. B. KILLIAN, G. F. HENNING, and J. A. NIEUWLAND (J. Amer. Chem. Soc., 1936, 58, 80–81; cf. A., 1934, 867).—Addition of  $\text{CH}_2\text{CBu}$  to ROH ( $\text{R}=\text{Et}$ -hexyl) containing small amounts of  $\text{CCl}_3\cdot\text{CO}_2\text{H}$  and a catalyst (prepared from red HgO and  $\text{BF}_3\cdot\text{Et}_2\text{O}$  in MeOH) at  $\geq 70^\circ$  gives  $\text{CMeBu}(\text{OR})_2$ , which are hydrolysed (dil.  $\text{H}_2\text{SO}_4$ ) to  $\text{COMeBu}$ .  $\beta\beta$ -Diethoxy-, b.p. 68–69°/18 mm.,  $\beta\beta$ -dipropoxy-, b.p. 95–97°/18 mm.,  $\beta\beta$ -dibutoxy-, b.p. 115–117°/18 mm.,  $\beta\beta$ -diamyloxy-, b.p. 141–143°/18 mm., and  $\beta\beta$ -dihexyloxy-, b.p. 143–144°/8 mm., -hexanes are described.  $\beta\beta$ -Diethoxy-, b.p. 81–83°/18 mm.,  $\beta\beta$ -dipropoxy-, b.p. 107–109°/18 mm.,  $\beta\beta$ -dibutoxy-, b.p. 134–136°/18 mm., and  $\beta\beta$ -diamyloxy-, b.p. 148–150°/17 mm., -heptanes are similarly prepared from  $\Delta^2$ -heptinene. Ketals could not be prepared from branched-chain AlkOH. H. B.

**Thermal decomposition of methyl hydrogen peroxide.**—See this vol., 164.

**Monoalkyl phosphites and their hydrolysis.** P. NYLÉN (Svensk Kem. Tidskr. 1936, 48, 2–22). The following monoalkyl phosphites, prepared by the action of NaOH on the appropriate dialkyl phosphite, are isolated as their Na salts: Me, m.p. 125 (decomp.); Et, m.p. 183–185°;  $\text{Pr}^\alpha$ , m.p. 195–196°;  $\text{Pr}^\beta$ , m.p. 132–133°; Bu $^\alpha$ , m.p. 177.5–178.5°. K for these H esters is determined in 3.98M-NaCl at 25°. Only the undissociated H ester is oxidised by acid 1; the anion is stable towards I. A method for following the hydrolysis of the esters by acids and alkalis is described, and the equilibrium of the system  $\text{H}_3\text{PO}_4\text{-EtOH-EtH}_2\text{PO}_3\text{-Et}_2\text{HPO}_3\text{-H}_2\text{O}$  is determined. The structure of the mono- and di-alkyl phosphites is discussed. J. N. A.

**Hydrolysis of the phosphoric ester of starch and glycogen.**—See this vol., 243.

**Formation of high polymerides by condensation between metal polysulphides and dihalogenated hydrocarbons and ethers.** J. C. PATRICK (Trans. Faraday Soc., 1936, 32, 347–357). Aliphatic hydrocarbons and ethers having a halogen on each of the terminal C condense with metal polysulphides, e.g.,  $\text{Na}_2\text{S}_4$ , to form linear polymerides of high mol. wt. with the respective empirical formulae  $\text{C}_2\text{H}_4\text{S}_4$  and  $\text{C}_4\text{H}_8\text{OS}_4$ . Both types frequently exhibit rubber-like properties. By treatment with NaOH half the S is removed, the residual substance losing its rubbery nature if formed from a hydrocarbon, but retaining it if formed from an ether. S can be re-introduced, and (in the former case) rubbery properties restored, by a process analogous to the vulcanisation of rubber. Theories of chemical structure and of the mechanism of the heat-vulcanisation are advanced. F. L. U.

**Preparation of lower alkanesulphonic acids.** D. L. VIVIAN and E. E. REID (J. Amer. Chem. Soc., 1935, 57, 2559–2560).—Anhyd. Alk $\cdot\text{SO}_3\text{H}$  are obtained from conc. aq. solutions after 4–5 distillation at 1 mm.; the pure acids soon darken even in a vac. The following are described: n-propane,

b.p. 136°/1 mm., m.p. 7.5°, *n*-butane-, b.p. 147°/0.5 mm., -15.2°, *n*-pentane-, b.p. 163°/1 mm., m.p. 15.9, and *n*-hexane, b.p. 174°/1 mm., m.p. 16.1°, -sulphonic acids. The alternation in m.p. resembles that for  $\text{Alk}\cdot\text{CO}_2\text{H}$ . H. B.

**Interaction of diazonium salts and acetone-sulphonic acid.** G. D. PARKES and S. J. M. FISHER (J.C.S., 1936, 83—85).—Diazotised  $p\text{-C}_6\text{H}_4\text{Br}\cdot\text{NH}_2$  and Na acetonesulphonate give Na methylglyoxal-*p*-bromophenylhydrazone- $\omega$ -sulphonate, m.p. 224° (decomp.). The following are similarly obtained: Na methylglyoxal-phenyl-, m.p. 195° (decomp.), -*p*-chlorophenyl-, m.p. 228° (decomp.), -2:4-dichlorophenyl-, m.p. 210° (decomp.), -2:4-dibromophenyl-, m.p. (decomp.), -*o*-nitrophenyl-, m.p. 256° (decomp.), -*m*-nitrophenyl-, m.p. 251° (decomp.), and -*p*-nitrophenylhydrazone- $\omega$ -sulphonate, m.p. 265° (decomp.). Na methylglyoxalphenylhydrazone- $\omega$ -sulphonate with 1 or 2 mols. yields  $\alpha$ -bromomethylglyoxal-*n*-bromophenylhydrazone, with 3 mols. of Br gives  $\beta\omega$ -dibromo- $\alpha$ -ketopropaldehyde-*p*-bromophenylhydrazone, and with excess of Br forms  $\beta\beta\omega$ -tribromo- $\alpha$ -ketopropaldehyde-2:4-dibromophenylhydrazone.

**Esterification as a gas reaction.**—See this vol.,

**Hydrolysis rates of some monoacid triglycerides under the influence of pancreas extract.** I.—See this vol., 297.

**Catalytic hydrogenation of acid chlorides in the vapour phase at atmospheric pressure.** N. and C. G. DANOV (J. pr. Chem., 1936, 217—224).—Hydrogenation (Pd-asbestos) of the appropriate acid chloride at the b.p. gives some  $\text{CHPr}\cdot\text{CHEt}\cdot\text{CHO}$ , isovaleryl-butyrolactone (54%), from succinyl chloride,  $\text{PhCHO}$  (89%),  $\text{CH}_2\text{Ph}\cdot\text{OH} + \text{PhEt}$ , and  $n\text{-C}_6\text{H}_{13}\text{COCl}$ . S and P compounds must be entirely absent. Raney Ni cannot be used. R. S. C.

**Catalysis in organic chemistry. V. Decompositions of esters and acids by anhydrous zinc chloride.** H. W. UNDERWOOD, jun., and O. L. BARN (J. Amer. Chem. Soc., 1935, 57, 2729—2730).— $\text{Alk}\cdot\text{CO}_2\text{H}$  (I) and their Me, Et, Pr, and Bu esters are unaffected by anhyd.  $\text{ZnCl}_2$  (II) (cf. A., 1930, 321; 1931, 1034); the amyl esters undergo slow decomposition (I) and unsaturated hydrocarbon (III). The rate of decomp. of  $\text{Alk}\cdot\text{CO}_2\text{Alk}'$  increases with the no. of C atoms in  $\text{Alk}'$ . The esters of aliphatic dibasic acids (IV) give the Zn salt of (IV) and HCl [which reacts with (III) to form  $\text{AlkCl}$ ].  $\text{ArCO}_2\text{R}$  decompose to (III) and  $\text{ArCO}_2\text{H}$  (which then gives  $\text{CO}_2$  and  $\text{ArH}$ ). All the (III) produced undergo polymerisation; the amount increases with the no. of C atoms. When (II) is insol. in the hot acid or ester no decomp. occurs. Numerous examples are given.  $\text{CH}_2\text{Cl}\cdot\text{CO}_2\text{H}$  gives  $\text{CO}$ ,  $\text{CH}_2\text{O}$ , and HCl;  $\text{CCl}_3\cdot\text{CO}_2\text{H}$  affords  $\text{CO}$ ,  $\text{COCl}_2$ , and HCl. H. B.

**Preparation of acetylenecarboxylic acids with sodamide. Synthesis of ethylpropionic acid.** A. E. FAVORSKI and V. O. MOCHNATSK (Bull. Far. Eastern Branch Acad. Sci. U.S.S.R., 1934, No. 9,

3 6; cf. A., 1888, 1168).—Treatment of  $\alpha\beta\text{-C}_4\text{H}_8\text{Br}_2$  with  $\text{NaNH}_2$  in kerosene, followed by passage of  $\text{CO}_2$ , gives a 46% yield of  $\Delta^2$ -pentenoic acid, b.p. 81—m.p. 50–6°. The prep. from  $\text{COMeEt}$  and  $\text{PCl}_5$ , followed by  $\text{NaNH}_2$  and  $\text{CO}_2$ , gave only poor yields. CH. ABS. (r)

**Tetradecenoic and dodecenoic acids in sperm oil.** I. Tetradecenoic and dodecenoic acids in sperm blubber oil. II. Dodecenoic acid in head oil. Y. TOYAMA and T. TSUCHIYA (Bull. Chem. Soc. Japan, 1935, 10, 563—569; 570—573).—I. After fractionation of their Me esters and hydrolysis, the fatty acids (2.4%) of sperm blubber oil (from *Physeter macrocephalus*, L.) are separated into fractions (i) b.p. 172—177°/15 mm., and (ii) b.p. 192 197°/15 mm. By the Pb-soap method (i) affords  $\Delta^8$ -dodecenoic acid (I), termed *denticetic acid*, converted into a Me dihydroxylaurate which gives  $n\text{-C}_6\text{H}_{13}\cdot\text{CO}_2\text{H}$  and glutaric acid (II) when oxidised with  $\text{KMnO}_4$  in  $\text{COMe}_2$ . Similarly (ii) gives  $\Delta^8$ -tetradecenoic acid (identical with physeric acid from sperm head oil), converted into a Me dihydroxy-myristate, oxidised ( $\text{KMnO}_4$ ) to  $n\text{-C}_8\text{H}_{17}\cdot\text{CO}_2\text{H}$  and (II). Neither  $\Delta^8$ -tetradecenoic nor  $\Delta^8$ -dodecenoic acid (Hilditch *et al.*, B., 1928, 307) could be detected.

II. (I) is isolated from the unsaturated fatty acids, b.p. 172 177°/15 mm., obtained by usual methods from sperm head oil, and its structure is established as above. J W

**Drying of oils and related unsaturated compounds.** R. S. MORRELL and W. R. DAVIS (Trans. Faraday Soc., 1936, 32, 209—215; cf. this vol., 298).—Of the possible combinations between maleic anhydride and  $\alpha$ - and  $\beta$ -elaeostearic acids, only one is formed with each, viz., at the pair of conjugated double linkings remote from the  $\text{CO}_2\text{H}$  in the  $\alpha$ - and nearer the  $\text{CO}_2\text{H}$  in the  $\beta$ -acid. The former (I) does not, and the latter (II) does, exhibit "drying" properties at room temp. Changes occurring in both compounds have been studied by measurements of the  $\text{O}_2$  absorbed, peroxide val., I val., and viscosity, and by examination of the chemical structure of the products. In (I) only the ethenoid linking in the aliphatic chain is oxidised, yielding a product with  $\cdot\text{CO}\cdot\text{CH}(\text{OH})\cdot$ , which undergoes no further change. In (II) a similar oxidation occurs at the ring ethenoid linking, whilst the remote aliphatic linking gives rise to a peroxide which is solely responsible for the ensuing polymerisation. Polymerisation in this, and in similar materials such as tung oil, is shown by a steady increase of viscosity which is accompanied by a concomitant disappearance of the peroxide radical. A chemical interpretation, supported by structural evidence, is put forward. The influence of polar and non-polar solvents is discussed.

F. L. U.

**Polymerisation in monolayers.**—See this vol., 298.

**Relative rates of ozonisation of unsaturated compounds.** C. R. NOLLER, J. F. CARSON, H. MARTIN, and K. S. HAWKINS (J. Amer. Chem. Soc., 1936, 58, 24—27).—The  $\text{O}_3$ -absorption curves (cf. Brus and Peyresblanques, A., 1930, 449, 588) for

oleic and elaidic acids, Me oleate, 1-phenyl- $\Delta^1$ -cyclohexene, and stilbene show that rapid addition of 1 mol. to the C:C occurs. The rate of addition decreases considerably with CHPh.CPh<sub>2</sub> and compounds containing  $\cdot\text{CH}:\text{CH}\cdot\text{CO}\cdot$  (e.g., vinylacetic, crotonic, cinnamic, and itaconic acids; CHMe:CH $\cdot$ CHO); a further decrease is observed with CPh<sub>2</sub>.CPh<sub>2</sub> and CHCl:CHCl. With compounds containing 2 or 3 double linkings (e.g., diphenylbutadiene; sorbic and elaeostearic acids), rapid addition of 1 mol. occurs; the rate then decreases. With geometrical isomerides which undergo relatively slow addition (e.g., Me fumarate and maleate; mesaconic and citraconic acids), the *trans*-form reacts more rapidly. H. B.

**Lipins of tubercle bacilli. XLII. Phthioic acid.** M. A. SPIELMAN and R. J. ANDERSON (J. Biol. Chem., 1936, **112**, 759—767; cf. this vol., 24).—Phthioic acid, C<sub>26</sub>H<sub>52</sub>O<sub>2</sub>, m.p. 20—21° (best purified by way of the Me ester, b.p. 158°/0.003 mm., [ $\alpha$ ]<sub>D</sub><sup>20</sup> +12.2° in Et<sub>2</sub>O, and characterised as *amide*, m.p. 45°), with CrO<sub>3</sub>-AcOH gives only a branched-chain acid, C<sub>11</sub>H<sub>20</sub>O<sub>2</sub> (p-C<sub>4</sub>H<sub>9</sub>CO $\cdot$ CH<sub>2</sub> ester, m.p. 49—50°; tribromoanilide, m.p. 111°). The *methylamide*, m.p. 27°, with PCl<sub>5</sub>-C<sub>6</sub>H<sub>6</sub> gives indefinite Cl nos. of no constitutive val. Grignard-CrO<sub>3</sub> degradation of the ester gives a mixture (impure *semicarbazone*, m.p. 55—65°). The acid is a polymethylated long-chain acid and probably has at least one Me close to the CO<sub>2</sub>H since [ $\alpha$ ]<sub>D</sub><sup>20</sup> +12.56° in Et<sub>2</sub>O, is high. The very pure acid retains the physiological properties previously reported. R. S. C.

**$\epsilon$ -Hexolactone.** F. J. VAN NATTA, J. W. HILL, and W. H. CAROTHERS (J. Amer. Chem. Soc., 1936, **58**, 183).—Partly a reply to Stoll and Rouvé (A., 1935, 1351). Further details (cf. A., 1934, 392) for the prep. of  $\epsilon$ -hexolactone are given. H. B.

**Highly polymerised compounds. CXXXIII. Viscosity of solutions of glycol esters and dicarboxylic esters.** H. STAUDINGER and H. MOSER (Ber., 1936, **69**, [B], 208—213).—The observed sp. viscosities of C<sub>6</sub>H<sub>6</sub> and CHCl<sub>3</sub> solutions of esters of higher fatty acids and decane- $\alpha\kappa$ -diol and of esters of sebacic and thapsiaic acid agree with those calc. from the formula  $\eta_{sp.}/c = 1.4\%$  and the temp. coeff. is the same as that observed with other aliphatic compounds of similar structure, thus showing that  $\eta_{sp.}$  of a solution depends essentially on the length of the mol. and is independent of its special structure. With derivatives of propane- $\alpha\gamma$ -diol the observed  $\eta_{sp.}$  is lower than the calc. but the temp. effect is normal. A shortening of the chain due to inter-attraction of the O atoms appears to be indicated. The following are incidentally described: *dilaurate*, m.p. 47—48°, *dimyristate*, m.p. 56—57°, and *dipalmitate*, m.p. 62—63°, of decane- $\alpha\kappa$ -diol; *dicetyl sebacate*, m.p. 53.5—54.5°; *dicetyl*, m.p. 62.5—63°, and *dioleyl*, m.p. 35—35.5°, *thapsiate*; *dilaurate*, m.p. 38—39°; *dimyristate*, m.p. 49.0—49.5° and *dipalmitate*, m.p. 54.5—55.5°, of propane- $\alpha\gamma$ -diol. H. W.

**Influence of heat and of the presence of various cations on oxalic acid solutions.** A. M. VASILIEV and N. I. PANOVA (Trans. Kirov Inst. Chem. Tech. Kazan, 1935, No. 3, 79—82).—H<sub>2</sub>C<sub>2</sub>O<sub>4</sub> is volatile

from conc. aq. solution on boiling. Most salts are stable but Mn causes loss of acid even in dil. solution.

CH. ABS. (7)

**Oxidation of ethyl hydrogen methylmalonate and of ethyl hydrogen succinate with potassium persulphate.** F. FICHTER and J. HEER (Helv. Chim. Acta, 1936, **19**, 149—154).—CO<sub>2</sub>K $\cdot$ CHMe $\cdot$ CO<sub>2</sub>Et and CO<sub>2</sub>K $\cdot$ CH<sub>2</sub>CH<sub>2</sub>CO<sub>2</sub>Et behave when oxidised with KSO<sub>4</sub> in the same manner as when electrolysed according to Crum Brown and Walker, EtCO<sub>2</sub>Et and CH<sub>2</sub>:CH $\cdot$ CO<sub>2</sub>Et being obtained in addition to ( $\cdot$ CHMe $\cdot$ CO<sub>2</sub>Et)<sub>2</sub> from the former and Et<sub>2</sub> adipate from the latter. Electrosynthesis is therefore an oxidation in the sense 2CO<sub>2</sub>H $\cdot$ CHMe $\cdot$ CO<sub>2</sub>Et + O = 2CO<sub>2</sub> + H<sub>2</sub>O + ( $\cdot$ CHMe $\cdot$ CO<sub>2</sub>Et)<sub>2</sub> and 2CO<sub>2</sub>H $\cdot$ CH<sub>2</sub>CH<sub>2</sub>CO<sub>2</sub>Et + O = ( $\cdot$ CH<sub>2</sub>CH<sub>2</sub>CO<sub>2</sub>Et)<sub>2</sub> + 2CO<sub>2</sub> + H<sub>2</sub>O. The yields of Et<sub>2</sub> esters are less by the oxidative than by the electrolytic method and decrease with increasing mol. wt. of the initial material. Et H methylmalonate has b.p. 111°/1 mm. H. W.

**Carbon dioxide cleavage from dibromomalonic acid. II.**—See this vol., 295.

**Formation of succinic acid by *B. coli*.**—See this vol., 247.

**Lichen substances. LXII. Components of *Cetraria islandica*, Ach.** Y. ASAHINA and M. YANAGITA (Ber., 1936, **69**, [B], 120—125).—*C. islandica*, Ach., from Hokkaido contains about 4% of a mixture of fatty acids which affords *d-protolichesteric acid* (I), m.p. 106°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> +12.07 in CHCl<sub>3</sub> when crystallised from AcOH, and *l-allo-protolichesteric acid* (II), m.p. 88°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> -56.34° in EtOH, [ $\alpha$ ]<sub>D</sub><sup>20</sup> -49.53° in CHCl<sub>3</sub>. Since (II) is transformed by warm Ac<sub>2</sub>O into *l*-lichesteric acid and converted by CH<sub>3</sub>N<sub>3</sub> into a *pyrazoline* derivative. C<sub>22</sub>H<sub>36</sub>O<sub>4</sub>N<sub>2</sub>, m.p. 68—69°, [ $\alpha$ ]<sub>D</sub><sup>18</sup> -73.69° in CHCl<sub>3</sub>, it is structurally identical with *protolichesteric acid*. It is oxidised by alkaline KMnO<sub>4</sub> to myristic acid. Treatment of the mixture of fatty acids with Ac<sub>2</sub>O at 100° gives *dl-lichesteric acid*, m.p. 115°, also obtained from its components. Catalytic hydrogenation (Pd in AcOH) of (II) affords *dihydro-l-allo-protolichesteric acid*, m.p. 92—93°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> -7.41 in CHCl<sub>3</sub>. Similarly, (I) gives *dihydro-d-protolichesteric acid*, m.p. 106°, [ $\alpha$ ]<sub>D</sub><sup>15</sup> +34.60° in CHCl<sub>3</sub>, transformed by CH<sub>3</sub>N<sub>3</sub> into a *pyrazoline* derivative, m.p. 54—55°, [ $\alpha$ ]<sub>D</sub><sup>18</sup> +190.60° in CHCl<sub>3</sub>. Extraction of the thall of Japanese *C. tenuifolia*, Retz, with H<sub>2</sub>O yields *d-protolichesteric acid*, m.p. 106°, [ $\alpha$ ]<sub>D</sub><sup>18</sup> -12.12° in CHCl<sub>3</sub>, hydrogenated to *dihydro-l-protolichesteric acid*, m.p. 106°, [ $\alpha$ ]<sub>D</sub><sup>18</sup> -30.96°, whence the *pyrazoline* derivative, m.p. 54—55°, [ $\alpha$ ]<sub>D</sub><sup>18</sup> -183.1° in CHCl<sub>3</sub>. H. W.

**Action of periodic acid on tartaric acid.** P. FLEURY and (MLLE.) G. BON-BERNATETS (J. Chim., 1936, [viii], 23, 85—99; cf. A., 1933, 591, Malaprade, A., 1934, 1090).—In the first stage of the reaction, which is complete in 5—10 min., H<sub>2</sub>O<sub>2</sub> gives up O, 2CHO $\cdot$ CO<sub>2</sub>H (I) being produced; in the second, which is complete in 36—48 hr. at room temp. (2 hr. at 37°), (I) is oxidised to HCO<sub>2</sub>H and CO<sub>2</sub>, taking O from HIO<sub>4</sub>. Hence each mol. of tartaric acid requires 3HIO<sub>4</sub> for completion of the reaction.

**Constitution of isopropylidenefurtondicarboxylic acids.** H. OHLE and N. SENGEL (Ber., 1936, 69, [B], 160—170; cf. A., 1929, 913; 1931, 72; 1932, 144, 148).—Oxidation of  $\beta$ -diisopropylidene-fructose (I) with  $\text{KMnO}_4$  ( $\equiv 4\text{O}$ ) gives  $K_2$   $\beta$ -isopropylidene-*l*-furtondicarboxylic acid, ( $+\text{H}_2\text{O}$ ) (II),  $[\alpha]_D^{25} +53.2^\circ$  in  $\text{H}_2\text{O}$  [corresponding  $\text{Ag}_2$  ( $+\text{H}_2\text{O}$ ),  $\text{Ba}$  ( $+\text{H}_2\text{O}$ ), and  $\text{Ca}$  ( $+\text{H}_2\text{O}$ ) salts]. (II) is transformed by pyridine-*l*-sulphonic acid in  $\text{C}_5\text{H}_5\text{N}$  into  $K_2$   $\beta$ -isopropylidene-*l*-furtondicarboxylate *l*-sulphate (III) (*loc. cit.*), so that (II) is the parent of (III). Methylation of the  $\text{Ag}$  salt of (II) affords  $\alpha$ -isopropylidenedioxy- $\beta$ -carbomethoxymethoxy- $\gamma$ -butyrolactone (IV) m.p.  $89.5^\circ$ ,  $[\alpha]_D^{25} +56.6^\circ$  in  $\text{MeOH}$ ,  $+64.2^\circ$  in  $\text{C}_6\text{H}_6$ , which regenerates (II) when hydrolysed by alkali, and *Me*  $\gamma$ -methoxy- $\alpha$ -isopropylidenedioxy- $\gamma$ -carbomethoxymethoxy-*n*-butyrate, b.p.  $140^\circ$  (bath)/0.05 mm.,  $[\alpha]_D^{25} +33.8^\circ$  in  $\text{MeOH}$ , hydrolysed by  $\text{KOH-MeOH}$  to  $K_2$   $\gamma$ -methoxy- $\alpha$ -isopropylidenedioxy- $\gamma$ -carbomethoxy-*n*-butyrate (V),  $[\alpha]_D^{25} +45.85^\circ$  in  $\text{H}_2\text{O}$  (corresponding  $\text{Ag}_2$  contains an active  $\text{H}$  of unknown location. When hydrolysed by acid it evolves  $\text{CO}_2$  with much greater difficulty than does (II). When treated with boiling  $\text{HCl-MeOH}$  it gives (in about 90% yield) hydroxyketonic acid, identified by dehydrogenation with  $p\text{-O:C}_6\text{H}_4\text{:O}$  and coupling with  $o\text{-C}_6\text{H}_4(\text{NH}_2)_2$  to the quinoxaline derivative,  $\text{C}_{16}\text{H}_9\text{O}_4\text{N}_2$ . Analogously (IV), (V) decomposes into  $\text{COMe}_2$ ,  $\text{CO}_2$ , and  $\text{OH}\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$ , but the expected dihydroxymethylacetone could not be detected with certainty. (III) therefore the structure shown and the analogy between fermentative and

Oxidative fission is purely formal. Examination of the graphs of the oxidation of (III) by  $\text{KMnO}_4$  in alkaline and neutral solution together with previous observations (*loc. cit.*) show that oxidation of (I) proceeds in two fundamentally different manners determined by  $[\text{H}^+]$  and  $[\text{OH}^-]$ , respectively. In alkaline solution the oxidant at first attacks almost exclusively the  $\text{OH}$  of  $\text{CH}_2\cdot\text{OH}$ . In neutral solution oxidation takes place preferentially at the  $\text{CH}$  linkings of the etherified  $\text{OH}$  groups.

H. W.

**Synthesis of vitamin-C from starch.** P. P. T. SAH (Ber., 1936, 69, [B], 158—159).—The synthesis of *l*-ascorbic acid (I) through the following steps is announced; the details will follow.  $\text{Starch} \rightarrow d\text{-saccharic acid} \rightarrow l\text{-gulonic acid} \rightarrow l\text{-gulonolactone} \rightarrow l\text{-glucose} \rightarrow l\text{-gulosazone} \rightarrow l\text{-gulosone} \rightarrow \alpha\text{-keto-}l\text{-gulonic acid} \rightarrow \text{Me } \alpha\text{-keto-}l\text{-gulonate} \rightarrow \text{(I)}$ .

H. W.

**Starch as a starting material for the synthesis of vitamin-C.** P. P. T. SAH (Sci. Rep. Nat. Tsing Hua Univ., 1935, C, 3, 265—277).—A detailed account of the work already reviewed (cf. preceding abstract). The possible, similar use of lactose is suggested.

H. W.

**Reactions of vitamin-C.**—See this vol., 255.

**Constitution of glauconic acids.** IV. H. SUTTER, F. ROTTMAYR, and H. PORSCH (Annalen, 1936, 521, 180—197; cf. A., 1935, 1224).—Proof that the thermal decomp. product of glauconic acid (A., 1933, 1143) is  $\text{CH}_2\text{Et}\cdot\text{CET}\cdot\text{CHO}$  is obtained by its oxidation with  $\text{Ag}_2\text{O}$  to the acid, b.p.  $116^\circ/13$  mm. (chloride,

b.p.  $62^\circ/13$  mm.; *amide*, m.p.  $117^\circ$ ), identical with a specimen synthesised by condensation of  $\text{CH}_2\text{EtBr}\cdot\text{CO}_2\text{Et}\cdot\text{Zn}\cdot\text{EtCHO}$  to give the *OH*-ester b.p.  $107\text{—}122^\circ/18$  mm., converted by  $\text{PCl}_5$  and subsequent hydrolysis with  $\text{KOH-EtOH}$  into  $\text{CH}_2\text{Et}\cdot\text{CET}\cdot\text{CO}_2\text{H}$ . The *amides* of tiglic, m.p.  $77^\circ$ , and of  $\beta\beta$ -dimethylacrylic acid, m.p.  $108^\circ$ , were prepared for comparison. Glauconic acid (I) m.p.  $188^\circ$ ,  $[\alpha]_D^{25} +189.6^\circ$  in  $\text{CHCl}_3$ , has equiv. 83, and gives a  $\text{Ag}_4$  salt which, with  $\text{MeI-MeOH}$  affords only a *Me*<sub>2</sub> ester, m.p.  $145^\circ$ . (I) gives a compound,  $\text{C}_{18}\text{H}_{21}\text{O}_6\text{N}$ , m.p.  $207\text{—}208^\circ$ , with  $\text{NH}_2\text{OH}$ , and a compound,  $\text{C}_{20}\text{H}_{22}\text{O}_4\text{H}_4$ , m.p.  $122^\circ$ , with  $\text{NHPh}\cdot\text{NH}_2$ . Reduction of (I) with  $\text{Zn-AcOH}$  affords (mainly) a dicarboxylic acid,  $\text{C}_{18}\text{H}_{27}\text{O}_7$ , m.p.  $209^\circ$  (*Me*<sub>2</sub> ester, m.p.  $161^\circ$ ), and traces of an acid,  $\text{C}_{20}\text{H}_{24(26)}\text{O}_7$ , m.p.  $201^\circ$  (*Me* ester, m.p.  $193\text{—}194^\circ$ ), and a neutral substance,  $\text{C}_{18}\text{H}_{22}\text{O}_6$ , m.p.  $192^\circ$ . (I) is stable to most oxidising agents, but with  $\text{NaOCl-NaOH}$  it gives a substance,  $\text{C}_{16}\text{H}_{20(22)}\text{O}_4\text{Cl}_2$ , m.p.  $200^\circ$ . The structure of (I), which probably contains the system  $\text{OH}\cdot\text{C}\cdot\text{C}\leq\text{C}\cdot\text{CO}\cdot\text{O}$  reduced to  $>\text{C}\cdot\text{C}\leq\text{C}\cdot\text{CO}$ , is briefly discussed.

J. W. B.

**Possibility of ring-chain mesomerism.** II. **Properties of  $\Delta^{\alpha\alpha}$ -hexadiene- $\alpha\gamma\gamma\delta\zeta\zeta$ -octacarboxylic esters.** C. K. INGOLD, M. M. PAREKH, and C. W. SHOPPEE (J.C.S., 1936, 142—153).—The work of Guthzeit and Hartmann (A., 1910, i, 386) on the ester obtained from Et sodiodicarboxyglutaconate and I has been repeated, without complete confirmation. The *Me* series has also been prepared and the constitution of the compounds is discussed. The observations do not support the *dicyclobutane* formula for the ester nor a structure with fused *cyclobutane* rings, but are in favour of (a) or (b). The corresponding

*Me* compounds are given in brackets. Oxidation of Et  $\Delta^{\alpha\alpha}$ -hexadiene- $\alpha\gamma\gamma\delta\zeta\zeta$ -octacarboxylate (I) [*Me*<sub>8</sub> ester (II), m.p.  $139^\circ$ ] with  $\text{KMnO}_4$  gives Et<sub>6</sub> H<sub>2</sub>  $\Delta^{\alpha\alpha}$ -hexadiene- $\alpha\gamma\gamma\delta\zeta\zeta$ -octacarboxylate [*Me*<sub>6</sub> ester m.p.  $218^\circ$  (decomp.)], which with  $\text{SOCl}_2$  yields the Et<sub>6</sub> ester dichloride,  $\text{C}_6\text{H}_2(\text{CO}_2\text{Et})_6(\text{COCl})_2$ , m.p.  $65\text{—}66^\circ$ . (I) and  $\text{HCl}$  afford Et<sub>4</sub> H<sub>2</sub> 3-hydroxy-2:4:4:5:5-pentacarboxycyclopentane-1-acetate, m.p.  $152^\circ$ , and its *anilide*, m.p.  $152^\circ$  [*Me* ester, m.p.  $245^\circ$  (decomp.)], converted into the neutral Et<sub>6</sub> ester, m.p.  $71^\circ$  [*Me*<sub>6</sub> ester, m.p.  $168^\circ$ ]. 3-Hydroxy-2:4:5-tricarboxycyclopentane-1-acetate, prepared by hydrolysis of the foregoing esters, has m.p.  $193^\circ$ , is stable to  $\text{KMnO}_4$ , and gives *Me* and *Et* esters; the constitution of this substance was given incorrectly by previous authors. Ozonolysis of (I) and (II) gives Et and *Me* ethane-tetracarboxylate, respectively. (II) and  $\text{NaOMe}$  afford *Me* 3-methoxy-2:2:4:4:5:5-hexacarboxycyclopentane-1-malonate, m.p.  $193^\circ$ , whilst thermal decomp. of (II) leads to *Me* 6-methoxy- $\alpha$ -pyrone-3:5-dicarboxylate. Electrolysis of (II) in  $\text{H}_2\text{SO}_4$  gives *Me*<sub>8</sub> dihydro-2:2:4:4:5:5-hexacarboxycyclopentane-1-malonate, m.p.  $149^\circ$ , which with  $\text{HCl}$  forms the *Me*<sub>6</sub> H<sub>2</sub> ester, m.p.  $252^\circ$  (decomp.), hydrolysed to 2:4:5-tricarboxycyclopentane-1-acetic acid, m.p.  $225^\circ$  [*Ag*

salt; *amide*, m.p. 280° (decomp.). The red  $\text{Na}_4$  salt of Guthzeit does not exist. *Me* 3-hydroxy-2:4:5-tricarboxycyclopentane-1-acetate is dehydrated ( $\text{KHSO}_4$ ) to a mixture of isomeric -pentene-1-acetates, reduced to a mixture of acids. F. R. S.

**Photochemical reactions of SH-compounds in solution.**—See this vol., 171.

**Derivatives of  $\beta$ -sulphopropionic acid.** L. A. BIGELOW, H. W. SIGMON, and D. H. WILCOX, jun. (J. Amer. Chem. Soc., 1935, 57, 2521—2524).—*Me*<sub>2</sub>, b.p. 132—133° (slight decomp.)/1 mm., m.p. 17°, *Et*<sub>2</sub>, m.p. 4°, *Pr*<sup>a</sup><sub>2</sub>, m.p. -7°, *Bu*<sup>a</sup><sub>2</sub>, m.p. -25°, and *di*-(phenylethyl), m.p. 59°,  $\beta$ -sulphopropionates are prepared from the anhyd.  $\text{Ag}_2$  salt (cf. Rosenthal, A., 1886, 866) and  $\text{RI}$ . The dry  $\text{K}_2$  salt and  $\text{PCl}_5$  in  $\text{C}_6\text{H}_6$  afford the unstable acid chloride ( $\text{I}$ ),  $\text{COCl}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{SO}_2\text{Cl}$ , m.p.  $-9\pm 1^\circ$  (cf. *loc. cit.*); the normal *dianilide*, m.p. 161°, is prepared. ( $\text{I}$ ) and dry  $\text{NH}_3$  in  $\text{C}_6\text{H}_6$  give (probably)  $\text{NH}_4$   $\beta$ -sulphopropionimide,  $\begin{matrix} \text{CH}_2\cdot\text{SO}_2 \\ \text{CH}_2\cdot\text{CO} \end{matrix} \text{N}\cdot\text{NH}_4$ , m.p. 164—168° (decomp.); the corresponding *Ba* salt and  $\text{H}_2\text{SO}_4$  (1 equiv.) do not give the imide, but afford some ( $\text{NH}_4$ )<sub>2</sub>  $\beta$ -sulphopropionate, m.p. 175—176° (shrinks at 170°), which passes at 111°/3—4 mm. into the  $\text{NH}_4$  *H* salt. H. B.

**Kinetics of reaction between peracetic acid and aldehydes.**—See this vol., 165.

**Reduction of aldehydes with aluminium isopropoxide.** W. G. YOUNG, W. H. HARTUNG, and F. S. CROSSLEY (J. Amer. Chem. Soc., 1936, 58, 100—102).— $\text{CHMe}\cdot\text{CH}\cdot\text{CH}_2\cdot\text{OH}$  is best prepared (58—60% yield) by reduction of  $\text{CHMe}\cdot\text{CH}\cdot\text{CHO}$  with  $\text{Al}(\text{OPr}^i)_3$  ( $\text{I}$ ) (from  $\text{Al}$  and  $\text{HgCl}_2$  in  $\text{Pr}^i\text{OH}$ ) in  $\text{Pr}^i\text{OH}$  at 110° (bath);  $\text{COMe}_2$  is removed continuously. Citronellal and  $\text{CHPh}\cdot\text{CH}\cdot\text{CHO}$  similarly give citronellol (32%) and  $\text{CHPh}\cdot\text{CH}\cdot\text{CH}_2\cdot\text{OH}$  (68%), respectively.  $\text{PrCHO}$  in  $\text{EtOH}$  at 25° or  $\text{C}_6\text{H}_6$  (b.p.) with ( $\text{I}$ ) gives 30 or 28%, respectively, of  $\text{Bu}^a\text{OH}$ ;  $\text{Al}(\text{OEt})_3$  and  $\text{OEt}\cdot\text{MgCl}$  (Meerwein and Schmidt, A., 1925, i, 1239) are much less efficient. The reaction mechanism is considered not to be a simple adaptation of the Cannizzaro reaction (cf. *loc. cit.*). H. B.

**Constitution of bisulphite additive compounds of aldehydes and ketones.** W. M. LAUER and C. M. LANGKANIMERER (J. Amer. Chem. Soc., 1935, 57, 2360—2362).— $\text{CH}_2\text{I}\cdot\text{SO}_3\text{K}$  ( $\text{I}$ ) (from  $\text{CHI}_3$  and aq.  $\text{K}_2\text{SO}_3$ ) and  $\text{KOAc}$  at 200—205° give *K* acetoxymethanesulphonate ( $\text{II}$ ) (crystallographic data given), also formed by acetylation ( $\text{Ac}_2\text{O}\cdot\text{AcOH}$ ) of the  $\text{KHSO}_3$  additive compound ( $\text{III}$ ) of  $\text{CH}_2\text{O}$ . ( $\text{III}$ ) is, therefore, *K* hydroxymethanesulphonate. ( $\text{I}$ ) is reduced ( $\text{Zn}$  dust,  $\text{EtOH}\cdot\text{AcOH}$ ) to  $\text{MeSO}_3\text{K}$  and with aq.  $\text{K}_2\text{SO}_3$  gives  $\text{CH}_2(\text{SO}_3\text{K})_2$ . ( $\text{II}$ ) and  $\text{NH}_2\text{Ph}$  afford *K* anilino-methanesulphonate ( $+\text{H}_2\text{O}$ ), converted by aq.  $\text{KCN}$  into  $\text{NHPh}\cdot\text{CH}_2\cdot\text{CN}$  (hydrolysed to  $\text{NHPh}\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$ ). ( $\text{II}$ ) and aq.  $\text{KCN}$  give  $\text{OAc}\cdot\text{CH}_2\cdot\text{CN}$ . Hydrolysis (dil.  $\text{H}_2\text{SO}_4$ ) of ( $\text{II}$ ) affords  $\text{CH}_2\text{O}$ .  $\text{CH}_2\text{I}\cdot\text{SO}_3\text{Na}$  ( $+\text{H}_2\text{O}$ ) is prepared as ( $\text{I}$ ). H. B.

**[Asymmetric] catalysis with organic fibres.**—See this vol., 170.

**Polymerisation of gaseous formaldehyde and acetaldehyde.**—See this vol., 298.

**Polymerides of acetaldehyde.** M. W. TRAVERS [in part with R. G. SOLLERS] (Trans. Faraday Soc., 1936, 32, 246—249).—By distilling dry air-free  $\text{MeCHO}$  into a bulb cooled in liquid air, a viscous or gelatinous product is obtained, the v.p. of which is, however, not measurably < that of the ordinary mobile liquid. On exposure to a vac., the product froths and ultimately becomes glassy. It slowly regenerates  $\text{MeCHO}$  in a sealed tube at 100°. Treatment of  $\text{MeCHO}$  with  $\text{H}_2\text{SO}_4\cdot\text{EtOH}$  at temp. not below -105° produces rapid polymerisation, a liquid compound, b.p. 73—75°, being formed. Its mol. wt., determined cryoscopically, corresponds with  $(\text{MeCHO})_n$ . It dissociates rapidly at 100°. F. L. U.

**Synthesis of deuteroacetaldehyde.** J. E. ZANNETTI and D. V. SICKMAN (J. Amer. Chem. Soc., 1935, 57, 2735).—Deuteroacetaldehyde (v.p. 327 mm. at 0°), prepared from  $\text{C}_2\text{D}_2$  and  $\text{D}_2\text{O}$ -acid-Hg salt, shows the usual aldehyde reactions. H. B.

**Decomposition of acraldehyde catalysed by iodine.**—See this vol., 167.

**Aldehyde condensations with secondary amines (Knoevenagel reaction).** R. KUHN, W. BADSTURNER, and C. GRUNDMANN (Ber., 1936, 69, [B], 98—107; cf. A., 1931, 1273).—The apparent discrepancy between the authors' results and those of Bernhauer *et al.* (A., 1932, 834) are explained by the observations that homogeneous crotonaldehyde ( $\text{I}$ ) is unchanged by piperidine ( $\text{II}$ ), whereas, after insolation, discoloration and separation of  $\text{H}_2\text{O}$  occur readily. The change is due to crotonic acid ( $\text{III}$ ) formed by autoxidation of ( $\text{I}$ ).  $\text{AcOH}$ ,  $\text{BzOH}$ , citric or cholic acid can replace ( $\text{III}$ ), but phenols are less efficient. It is therefore probable that the Knoevenagel reaction is generally catalysed by salts of *sec.* bases rather than by the bases themselves and an equimol. mixture of ( $\text{II}$ ) and glacial  $\text{AcOH}$  diluted with a little abs.  $\text{EtOH}$  is found very serviceable. Decatetraenal,  $\text{Me}\cdot[\text{CH}\cdot\text{CH}]_4\cdot\text{CHO}$ , m.p. 107—107.5° (hydrazone, complete decomp. 280° after softening and darkening at 190°), is thus derived from ( $\text{I}$ ) and sorbaldehyde or from  $\text{MeCHO}$  and octatrienal. It condenses with  $\text{CH}_2(\text{CO}_2\text{Et})_2$  to decatetraenalmalonic acid, which gradually decomposes when heated and is decarboxylated, best by boiling  $\text{AcOH}\cdot\text{Ac}_2\text{O}$ , to dodecapentaenoic acid, m.p. 247° (decomp.); the *Me* ester, m.p. 190.5°, becomes polymerised and autoxidised when exposed to air. Citrylideneacetaldehyde,  $\text{CMe}_2\cdot\text{CH}\cdot[\text{CH}_2]_2\cdot\text{CMe}\cdot\text{CH}\cdot\text{CH}\cdot\text{CH}\cdot\text{CHO}$ , b.p. 93—94/0.02 mm., obtained from citral and excess of  $\text{MeCHO}$  in presence of ( $\text{I}$ )- $\text{AcOH}$  but not of ( $\text{I}$ ), can be preserved unchanged in vac. in the dark, but rapidly resinifies when exposed to air; it has a strong odour of over-ripe pears, and differs in this respect and in its physical consts. from the product of von Braun *et al.* (A., 1934, 1335). The possibility of *cis-trans*-isomerism is not supported by attempted isomerisation by irradiation,  $\text{I}$ , etc. It gives a semicarbazone, m.p. 166—167°, and a 2:4-dinitrophenylhydrazone, m.p. 132—133°. It is transformed by boiling 10%  $\text{K}_2\text{CO}_3$  into  $\text{MeCHO}$  and methylheptenone. When

heated with  $\text{Ag}_2\text{O}$  it is oxidised (with partial hydrolysis) to *citrylideneacetic acid*, b.p. 115—120°/0.002 mm., hydrogenated ( $\text{PtO}_2$ ) to *dl-80-dimethyldecoic acid*, b.p. 160—162°/12 mm. (*p*-bromophenacyl ester, m.p. 56°). Treatment of it with  $\text{Al}(\text{OPr}^i)_3$  affords *citrylidene-ethyl alcohol* ( $\epsilon\epsilon$ -dimethyl- $\Delta^{8,10}$ -decatrienyl alcohol), b.p. 102—105°/0.03 mm. H. W.

**Detection of methylglyoxal and fission of caoutchouc by ozone.** R. PUMMERER, G. MATTHÄUS, and W. SOCIAS-VINALS [with, in part, F. BRAUN] (Ber., 1936, 69, [B], 170—183).—The possibility of recognising  $\text{AcCHO}$  in presence of laevulaldehyde (I),  $\text{MeCHO}$ , and  $\text{CH}_2\text{O}$  (as products of ozonisation of caoutchouc) is impeded by the impossibility of separating (I) and  $\text{AcCHO}$  by means of  $(\text{NO}_2)_2\text{C}_6\text{H}_3\cdot\text{NH}\cdot\text{NH}_2$ . The pptn. of Ni methylglyoxime is not sufficiently complete in dil. solution. The most suitable reagent is  $\text{NH}_2\cdot\text{CO}\cdot\text{NH}\cdot\text{NH}_2$ , which in very dil. solution gives 91% yields of methylglyoxaldisemicarbazone (II) without co-pptn. of laevulaldehydesemicarbazone. (II) is subsequently transformed by 17%  $\text{H}_2\text{SO}_4$  into methylglyoxal-2 : 4-dinitrophenylosazone (yield 95%). A more complex separation of  $\text{AcCHO}$  and (I) is effected by *p*- $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{NH}\cdot\text{NH}_2$ . Comparative experiments with  $\text{O}_3$  and mesityl oxide in  $\text{CCl}_4$  and  $\text{H}_2\text{O}$  give only 7.4% and 18% yields of  $\text{AcCHO}$ , which are increased to 29% in  $\text{CHCl}_3$  at 0° followed by very cautious fission of the ozonide by  $\text{SO}_2$ . The mean yield of  $\text{MeCHO}$  from caoutchouc is 1%, but this is observed only after over-ozonisation. If the action of  $\text{O}_3$  is interrupted as soon as the  $\text{CHCl}_3$  solution has become stable to Br, the production of  $\text{AcCHO}$  is  $\approx 0.1\%$  in any case. The view that  $\text{AcCHO}$  is a secondary product is discounted by the observation that, after a certain period, further over-ozonisation does not affect the yield of  $\text{AcCHO}$ . If aq.  $\text{SO}_2$  is used for fission of the ozonide,  $\text{AcCHO}$  is not detected even after prolonged ozonisation. A terminal isoprene group with a conjugated system is therefore not present in 1000 isopentene groups of caoutchouc. *Uttapercha* behaves similarly, giving no  $\text{AcCHO}$  without over-ozonisation if  $\text{SO}_2$  is used for fission of the ozonide and about 1% of  $\text{AcCHO}$  if  $\text{H}_2\text{O}$  at 0° is employed. The occurrence of  $\text{MeCHO}$  among the products of ozonisation is unexplained. Methylglyoxaldehyde when ozonised or over-ozonised and then treated with  $\text{SO}_2$  does not give  $\text{AcCHO}$ . Over-ozonisation and subsequent treatment with  $\text{H}_2\text{O}$  at 0° gives 0.6—0.8% of the C skeleton as  $\text{AcCHO}$  and an almost equiv. amount of  $\text{H}_5\text{C}_2\text{O}_4$ . H. W.

**Enolisation as directed by acid and basic catalysts. III. Acid-catalysed enolisation of sec.-butyl ketones.** P. D. BARTLETT and C. H. STAUFFER (J. Amer. Chem. Soc., 1935, 57, 2580—2583).—The rates of racemisation ( $k_R$ ) and iodination ( $k_I$ ) of *d*-COPh-CHMeEt in AcOH containing  $\text{HNO}_3$  (1.19N) (catalyst) at 36.75° are identical. Similarly,  $k_R$  and  $k_I$  are determined for *d*-COR-CHMeEt ( $\text{R} = \text{Me, Et, CH}_2\text{Ph, and cyclohexyl}$ ) at 25° (and other temp.); the competitive rates of the enolisations involving the H of CHMeEt and R are calc. The mechanism previously advanced (A., 1934, 607) does not permit an explanation of the relationship

between enolisation and alkyl substitution. The vals. of  $k_R$  and  $k_I$  for menthone (*ibid.*, 153) are revised.

H. B.

**Reactions of tagetone. I.** T. G. H. JONES (Proc. Roy. Soc. Queensland, 1934, 45, 45—49; cf. A., 1926, 72).—Tagetone (I) is represented as a tautomeric mixture:  $\text{COBu}^s\cdot\text{CH}_2\cdot\text{C}(\text{CH}_3)_2\cdot\text{CH}\cdot\text{CH}_2\cdot\text{OH}$ ,  $\text{OH}\cdot\text{CBu}^s\cdot\text{CH}\cdot\text{C}(\text{CH}_3)_2\cdot\text{CH}\cdot\text{CH}_2$ ,  $\text{COBu}^s\cdot\text{CH}\cdot\text{CMe}\cdot\text{CHMe}$ ,  $\text{CH}\cdot\text{CH}_2$ . Reduction of (I) with Na-EtOH yields *dihydrotagetol*,  $\text{C}_{10}\text{H}_{20}\text{O}$ , b.p. 197°/760 mm., which is not  $\gamma$ -0-dimethyl- $\Delta^8$ -octen- $\epsilon$ -ol. Reduction of (I) with Zn dust and EtOH- $\text{NH}_4\text{Cl}$  yields a non-homogeneous *dihydrotagetone* (II),  $\text{C}_{10}\text{H}_{18}\text{O}$ , b.p. 186—190°, with two dimeric products,  $\text{C}_{20}\text{H}_{36}\text{O}$ , b.p. 115—120°/4 mm., and  $\text{C}_{20}\text{H}_{34}\text{O}_2$ , b.p. 140—150°/4 mm. (II) on oxidation yields  $\text{Bu}^s\text{CO}_2\text{H}$  and a *CO-acid*,  $\text{C}_9\text{H}_{16}\text{O}_3$ ; it is, therefore,  $\text{COBu}^s\cdot\text{CH}_2\cdot\text{CMe}\cdot\text{CHMe}$  containing a little  $\text{COBu}^s\cdot\text{CH}_2\cdot\text{CHMe}\cdot\text{CH}\cdot\text{CH}_2$ . Reduction of (I) with Zn and EtOH-NaOH yields a *monoketone*,  $\text{C}_{10}\text{H}_{18}\text{O}_2$ , b.p. 140—150°/4 mm. (*monoxime*), and an isomeric *diketone*, b.p. 160—170°/4 mm. (*dioxime*), together with a little low-boiling liquid (*semicarbazone*, m.p. 92.5°). Reduction of (I) with Na-Hg and EtOH or with Al-Hg and EtOH affords intractable mixtures of pinacols. Treatment of (I) with  $\text{H}_2\text{S}$  in  $\text{NH}_3$ -EtOH yields a S-containing substance b.p. 90°/4 mm. With  $\text{Ba}(\text{OH})_2$  in MeOH (I) affords a *CO-alcohol*,  $\text{C}_{10}\text{H}_{18}\text{O}_2$ , b.p. 75—80°/4 mm., with  $\text{COMeBu}^s$ . (I) with  $\text{MgMeI}$  yields a substance, b.p. 66°/3 mm., and two *polymerides*,  $\text{C}_{10}\text{H}_{32}\text{O}_2$ , b.p. 130—140°/4 mm., and 150—160°/4 mm. With  $\text{NH}_2\text{OH}$  in alkaline solution an oxime is formed, whilst in dil.  $\text{H}_2\text{SO}_4$  an *oximinoketone*, b.p. 100—102°/4 mm., is produced.

CH. ABS. (r)

**Steric transformation of sugars.** F. JUST (Z. Spiritusind., 1936, 59, 25, 33—34).—A review of the methods used in effecting steric transformation of sugars leads to the conclusion that Walden inversion during fission of the O bridge in anhydro-sugars is more promising preparatively than treatment of the sugars with alkali or  $\text{C}_2\text{H}_5\text{N}$  or of unsaturated sugar derivatives with  $\text{BzO}_2\text{H}$ .

H. W.

**Structure of *d*-xylomethylose.** P. A. LEVENE and J. COMPTON (J. Biol. Chem., 1936, 112, 775—783).—*iso*Propylidene-*d*-xylomethylose and  $\text{MeI}-\text{Ag}_2\text{O}$  at 50° give the 3-*Me ether*, b.p. 58—60°/0.3 mm.,  $[\alpha]_D^{25} -49.4^\circ$ , hydrolysed by hot 1%  $\text{H}_2\text{SO}_4$  to 3-methyl-*d*-xylomethylose, b.p. 101—102°/0.8 mm.,  $[\alpha]_D^{25} +8.1^\circ$  (*phenylosazone*, m.p. 128—130°), which with  $\text{HCl}-\text{MeOH}$  affords  $\alpha$ -, b.p. 58—62°/0.3 mm.,  $[\alpha]_D^{25} +124.5^\circ$ , and  $\beta$ -methyl-3-methyl-*d*-xylomethyloside, b.p. 72—75°/0.3 mm., m.p. 48—50°,  $[\alpha]_D^{25} -127.9^\circ$ . These with  $\text{MeI}-\text{Ag}_2\text{O}$  at 50° yield  $\alpha$ -, m.p. 34—35°, b.p. 39—41°/0.5 mm.,  $[\alpha]_D^{25} +154^\circ$ , and  $\beta$ -methyl-2 : 3-dimethyl-*d*-xylomethyloside, b.p. 38—40°/0.5 mm.,  $[\alpha]_D^{25} -102.4^\circ$ , respectively, both oxidised by conc.  $\text{HNO}_3$  to *d*-[CH(OMe) $\cdot\text{CO}_2\text{H}$ ] $_2$ . *d*-Xylomethylose (I) and  $\text{Ag}_2\text{O}-\text{H}_2\text{O}$  at 80° give only  $\text{AgOAc}$ . The rate of lactonisation of *d*-gulomethylonic acid indicates formation of  $\gamma$ - and  $\delta$ -lactones. The structure of (I) is thus confirmed.  $[\alpha]$  are in  $\text{H}_2\text{O}$ . R. S. C.

**Ring closure in sugar benzoates.** M. L. WOLFROM and C. C. CHRISTMAN (J. Amer. Chem. Soc.,

1936, 58, 39—43).—Successive treatment of *l*-arabinose  $\text{Et}_2$  mercaptal with  $\text{CPh}_3\text{Cl}$  and  $\text{BzCl}$  in  $\text{C}_5\text{H}_5\text{N}$  at room temp. gives 5-triphenylmethyl-*l*-arabinose  $\text{Et}_2$  mercaptal tribenzoate, m.p. 111—112°,  $[\alpha]_D^{25} -25^\circ$  in  $\text{CHCl}_3$ , converted by  $\text{AcOH-HBr}$  followed by  $\text{CdCO}_3 + \text{HgCl}_2$  in aq.  $\text{COMe}_2$  into *l*-arabinose 2:3:4-tribenzoate (I), m.p. 162—163°,  $[\alpha]_D^{25}$  (in  $\text{C}_5\text{H}_5\text{N}$ )  $+143^\circ \rightarrow +196^\circ$ . Equilibration of *l*-arabinose in  $\text{C}_5\text{H}_5\text{N}$  and subsequent treatment with  $\text{BzCl}$  affords  $\alpha$ -*l*-arabinose tetrabenzoate (II), m.p. 160—161°,  $[\alpha]_D^{25} +112.5^\circ$  in  $\text{CHCl}_3$  [also prepared by benzylation of (I)], converted by cold  $\text{AcOH-HBr}$  into benzobromo-*l*-arabinose, m.p. 144—145°,  $[\alpha]_D +203^\circ$  in  $\text{CHCl}_3$ , which is hydrolysed (method: Fischer and Noth, A., 1918, i, 225) to (I).  $\beta$ -*l*-Arabinose tetrabenzoate has m.p. 173—174°,  $[\alpha]_D +325^\circ$  in  $\text{CHCl}_3$  (cf. Gehrke and Aichner, A., 1927, 544). The above reactions are considered to support the pyranose structure of (II). *d*-Galactose  $\text{Et}_2$  mercaptal tetrabenzoate, m.p. 127—128°,  $[\alpha]_D^{25} -16.5^\circ$  in  $\text{CHCl}_3$  [from the 6-CPh<sub>3</sub> ether (III) (A., 1935, 734) and  $\text{AcOH-HBr}$ ], with  $\text{CdCO}_3 + \text{HgCl}_2$  in aq.  $\text{COMe}_2$ , gives *d*-galactose tetrabenzoate (+MeOH), m.p. 112—113°,  $[\alpha]_D^{25}$  (in  $\text{CHCl}_3$ )  $-10^\circ \rightarrow +6.5^\circ$ .  $\text{HBr}$  converts (III) (in  $\text{CHCl}_3$ ) into 6-bromo-*d*-galactose  $\text{Et}_2$  mercaptal tetrabenzoate, m.p. 103—104°,  $[\alpha]_D^{25} -1.4^\circ$  in  $\text{CHCl}_3$ ,  $\alpha$ -*d*-Galactose pentabenzoate, m.p. 128—129°,  $[\alpha]_D +187^\circ$  in  $\text{CHCl}_3$ , is prepared by Levene and Meyer's method (A., 1928, 398). Triphenylmethyl-*d*-mannose  $\text{Et}_2$  mercaptal tetrabenzoate, m.p. 105—106°,  $[\alpha]_D^{25} 0^\circ$ ,  $[\alpha]_D^{50} -10.5^\circ$  in  $\text{CHCl}_3$  (corresponding tetraacetate, m.p. 133.5—134.5°,  $[\alpha]_D^{25} +36^\circ$  in  $\text{CHCl}_3$ ), is converted [as for (III)] into *d*-mannose  $\text{Et}_2$  mercaptal tetrabenzoate, m.p. 116—117°,  $[\alpha]_D^{25} -5^\circ$  in  $\text{CHCl}_3$ , and thence into *d*-mannose tetrabenzoate,  $[\alpha]_D^{25} -115^\circ$  in  $\text{CHCl}_3$ . Glucose  $\text{Et}_2$  mercaptal pentabenzoate (Brigl and Muchschlegel, A., 1930, 1022) with  $\text{CdCO}_3 + \text{HgCl}_2$  in aq.  $\text{COMe}_2$  gives aldehydoglucose pentabenzoate, m.p. 81—82°,  $[\alpha]_D^{25} +40^\circ$  in  $\text{EtOH}$  (cf. *loc. cit.*). Kunz and Hudson's method of hydrolysis (A., 1926, 941) is applicable to sugar benzoates provided they are appreciably sol. in  $\text{H}_2\text{O}$ . H. B.

**Esters of aldehydol form of sugars.** M. L. WOLFROM (J. Amer. Chem. Soc., 1935, 57, 2498—2500).—aldehydoGalactose penta-acetate  $\text{Et}$  hemiacetal (A., 1930, 1023) with  $\text{AcHal}$  gives aldehydo-1-chloro-, m.p. 174—175°,  $[\alpha]_D^{25} -44^\circ$  in  $\text{CHCl}_3$ , -1-bromo-, m.p. 179—181°,  $[\alpha]_D^{25} -79^\circ$  in  $\text{CHCl}_3$ , and -1-iodo-, m.p. 152—153°,  $[\alpha]_D^{25} -111^\circ$  in  $\text{CHCl}_3$ , -*d*-galactose hexa-acetates; these compounds are the open chain analogues of the cyclic halogenosugar acetates. Acetylation ( $\text{Ac}_2\text{O}$  and  $\text{C}_5\text{H}_5\text{N}$  or  $\text{ZnCl}_2$  at room temp.) of aldehydo-*d*-glucose penta-acetate affords the hepta-acetate, m.p. 118.5—119.5°,  $[\alpha]_D^{25} +8^\circ$  in  $\text{CHCl}_3$ ; aldehydo-*l*-arabinose tetra-acetate gives the hexa-acetate, m.p. 89.5°,  $[\alpha]_D^{25} -27^\circ$  in  $\text{CHCl}_3$ . These  $\text{C}_5\text{H}(\text{OAc})_2$  derivatives are much more stable than the aldehydo-forms. H. B.

**Action of hot alkali solutions on carbohydrates.** R. S. HILPERT and A. WOLTER (Angew. Chem., 1936, 49, 54—55).—Carbohydrates are heated with aq.  $\text{Na}_2\text{CO}_3$ , and the amount of acid produced is determined from the  $\text{CO}_2$  evolved. This varies from zero for gum arabic to 0.18 g. of  $\text{CO}_2$  per g. of mono-

saccharide at 100°. The amount increases rapidly with rise of temp. up to 0.3 at 170°. Sucrose is stable up to 130°.  $\text{OH}\cdot\text{CHMe}\cdot\text{CO}_2\text{H}$  was not found in the liquors. S. M. N.

**Constitution of osazones.** L. L. ENGEL (J. Amer. Chem. Soc., 1935, 57, 2419—2423).—The absorption spectra of the osazones (I) of various sugars (e.g., glycerose, glucose, lactose, 3:4:6-trimethyl-, tetra-acetyl- and -benzoyl-glucose) are all markedly similar; the group responsible for the sp. absorption is considered to be

$\text{NHPh}\cdot\text{N}\cdot\text{CH}\cdot\text{C}(\text{N}\cdot\text{NHPh})\cdot\text{CH}\cdot\text{OR}$  ( $\text{R}=\text{H}$ , alkyl, or acyl). The difference between the curves for (I) and the osazones of  $\text{AcCHO}$  and  $\text{Ac}_2$  (both of which are almost identical) is ascribed to the  $\text{C}_3\cdot\text{O}$  in (I). The mutarotation of (I) may be due to the establishment of an equilibrium between (I) and their hydrolysis products. A related equilibrium appears to be established between 3:4:6-trimethylglucosephenylosazone,  $[\alpha] -48.8^\circ \rightarrow +61.5^\circ$  (after 188 hr.) (in  $\text{EtOH-C}_5\text{H}_5\text{N}$ ), and  $\text{NHPh}\cdot\text{NH}_2$  (16.3 mols.); the change  $[\alpha] -50.6^\circ \rightarrow +30^\circ$  (after 155 hr.) being observed.

Acetylation ( $\text{Ac}_2\text{O}$ ,  $\text{C}_5\text{H}_5\text{N}$ ) of glucosephenylosazone (II) and fructosephenylmethylosazone (III) gives the  $\text{Ac}_4$  derivatives, m.p. 102—104° (corr.),  $[\alpha]_D^{25} -58.5^\circ$  in 95%  $\text{EtOH}$ , and m.p. 126—127° (corr.),  $[\alpha]_D^{27} -184.8^\circ$  in 95%  $\text{EtOH}$ . (III) and  $\text{NHPh}\cdot\text{NH}_2$  in  $\text{MeOH}$  at room temp. afford glucosephenylphenylmethylosazone; the *p*-nitrophenylphenylmethylosazone, m.p. 223.5—224.5° (corr.), is similarly prepared using *p*- $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{NH}\cdot\text{NH}_2$ . isoPropylidene-galactosephenylosazone, m.p. 183.5—184.5° (corr.), is formed from the galactosazone,  $\text{COMe}_2$ , and  $\text{P}_2\text{O}_5$  at 0°. Acetylglucose-2:4-dinitrophenylosazone, m.p. 196—197° (corr.), is obtained from  $\text{CO}(\text{CH}_2\cdot\text{OAc})_2$  [prep. by oxidation ( $\text{Na}_2\text{Cr}_2\text{O}_7$ ,  $\text{AcOH-H}_2\text{SO}_4$ ) of diacetin described]. Methylation (various conditions) of (II) gives non-homogeneous products. Votoček and Valentin's results (A., 1931, 1274) on the mutarotation of (III) could not be confirmed. H. B.

**Photolysis of fructose in ultra-violet light.**—See this vol., 299, 300.

**Hydrolysis of glucosides and of certain organic compounds by ultra-violet rays.**—See this vol., 171.

**Synthesis and properties of  $\beta$ -alkylglucosides.** S. VEIBEL and F. ERIKSEN (Bull. Soc. chim., 1936, [v], 3, 277—283).— $\beta$ -Methyl-, -ethyl-, m.p. 81—83°,  $[\alpha]_D^{20} -38.6^\circ$  in  $\text{H}_2\text{O}$  (tetra-acetate, m.p. 105—106°,  $[\alpha]_D^{20} -29^\circ$  in  $\text{C}_5\text{H}_5$  or  $\text{EtOH}$ ), -propyl-, forms, m.p. 77—78° (I) and 102—103° (II), respectively,  $[\alpha]_D^{20} -39.3^\circ$  in  $\text{H}_2\text{O}$  [(I)  $\rightarrow$  (II) at 90—95°; (II)  $\rightarrow$  (I) in  $\text{PhMe}$  slowly at 30° and rapidly if boiled and then cooled to 70°; tetra-acetate, m.p. 102—103°,  $[\alpha]_D^{25} -27^\circ$  in  $\text{EtOH}$ ], and -isopropyl-glucoside, m.p. 128—129°,  $[\alpha]_D^{20} -40.9^\circ$  in  $\text{H}_2\text{O}$  (tetra-acetate, m.p. 136—137°,  $[\alpha]_D^{25} -30.6^\circ$  in  $\text{EtOH}$ ), are prepared (a) from penta-acetylglucosidyl bromide and subsequent hydrolysis by a trace of  $\text{NaOMe}$  and (b) by emulsin from glucose with removal of the excess of glucose  $\gamma$  yeast. M.p. are corr. R.

**Synthesis of 1-*d*-glucosidocytosine.** G. E. HILBERT and E. F. JANSEN (J. Amer. Chem. Soc., 1936, 58, 60—62).—2:4-Diethoxypyrimidine and acetobromoglucose at 65° give 2-*keto*-4-ethoxy-1-tetra-acetyl-*d*-glucosido-1:2-dihydropyrimidine, m.p. 206° (corr.),  $[\alpha]_D^{25} + 36.1^\circ$  in CHCl<sub>3</sub>, converted by EtOH-HCl into 1-*d*-glucosidouracil (I) (A., 1931, 100) and by EtOH-NH<sub>3</sub> at 80°/96 hr. in sealed tube into 1-*d*-glucosidocytosine (II) (+ $\frac{1}{3}$ EtOH), m.p. 197—199° (sinters at 192°) [picrate, m.p. 216—218° (decomp.); nitrate (+H<sub>2</sub>O), m.p. 143° (decomp.)], which when kept in a moist atm. passes into a hydrate, m.p. about 128° (decomp.). Crystallisation from 90—95% EtOH gives a hydrate-alcoholate, m.p. 194—195° (decomp.). Anhyd. (II) is hygroscopic and has  $[\alpha]_D^{25} + 25.6^\circ$  in H<sub>2</sub>O. (II) with 25% H<sub>2</sub>SO<sub>4</sub> at 150° gives (probably) a mixture of (I) and (II). 7-Acetyl-1-tetra-acetylglucosidocytosine has m.p. 225°,  $[\alpha]_D^{25} + 38.1^\circ$  in CHCl<sub>3</sub>. H. B.

**Influence of crystalloids on the state of amyloses.**—See this vol., 288.

**Plant colloids. XLIII. Influence of chlorine dioxide on the chemical reactions of potato- and wheat-starch.** M. SAMEC [with F. ULM] (Kolloid-Beih., 1936, 43, 287—294).—When treated with ClO<sub>2</sub> solutions, starch loses P and N. A considerable amount of P in potato- (but not wheat-) starch resists this action. The treatment also renders the starch more sol., and in some cases causes feeble oxidation. E. S. H.

**Kinetics of long chain disintegration applied to cellulose and starch.**—See this vol., 295.

**Origin of nitrous oxide and hydrogen cyanide formed by certain methods of decomposition of cellulose nitrate.** H. MURAUOR (Bull. Soc. chim., 1936, [v], 3, 265—267).—Decomp. of cellulose nitrate leads to HNO, which at low temp. gives N<sub>2</sub>O and at high temp. reacts with CH<sub>4</sub> to produce HCN. R. S. C.

**Highly polymerised compounds. CXXIII. Measurements of the viscosity of aliphatic amines with long chains.** H. STAUDINGER and K. RÖSSLER (Ber., 1936, 69, [B], 49—60).—Determinations of the viscosity of long-chained aliphatic nitriles and primary and *sec.*-amines show the compounds to be unimol. in C<sub>6</sub>H<sub>6</sub> and CCl<sub>4</sub>, since the observed  $\eta_{sp}$ . (1.4%) vals. agree with those calc. from the expression  $\eta_{sp}$ . (1.4%) =  $\eta\eta$ . The temp. coeff. is the same as that of hydrocarbons. With short-chain compounds the observed vals. are < the calc., since the abs. viscosity of the dissolved substance is not sufficiently high in comparison with that of the solvent. The amine mol. has therefore the form R-NH-R, not NHR<sub>2</sub>. *tert.*-Amines with three long chains have the mol. structure  $\begin{matrix} R & R & R \\ & \diagdown & / \\ R-N & -N- & N-R \\ & / & \diagdown \\ R & R & R \end{matrix}$ , not  $\begin{matrix} R & R \\ & \diagdown & / \\ R-N & -N- & N \\ & / & \diagdown \\ R & R \end{matrix}$ , and are thus comparable with the glyceryl esters. The viscosity of long-chained amines in heteropolar solvents is quite irregular and is little affected by the addition of electrolytes. Since micelle formation is not involved, an adequate explanation of the high sp. viscosity in AcOH is not forthcoming. Amines

and nitriles, like hydrocarbons and esters, exist in solution as thread mols. with the most extended form; from these the crystals are formed and m.p. and solubility of the solids depend greatly on the length of the chains. Nitriles have a somewhat higher m.p. (about 9°) than hydrocarbons with the same no. of chain links. Primary amines and primary alcohols have the same m.p. (20—30° > that of the corresponding hydrocarbons); their mols. are therefore coordinatively united but so weakly that the union is broken in solution. The very low m.p. of *tert.*-amines is explained by their branched structure. *sec.*-Amines with two long chains have m.p. slightly < the corresponding hydrocarbons due to the slightly less regular structure, whilst Me-substituted *tert.*-amines have m.p. similar to that of hydrocarbons containing Et attached to the central C. The following compounds are incidentally described: *dimyristylamine*, m.p. 56—58.5°; *dicetylamine*, m.p. 65—66°; *dimethylmyristylamine*, liquid at 0°; *dimethylcetylamine*, m.p. about 12°; *dimethylstearylamine*, m.p. about 25°; *methylmyristylamine*, m.p. 24—25°; *methylcetylamine*, m.p. 34—35°; *methylstearylamine*, m.p. 40°; *trimyristylamine*, m.p. 33—34°; *tricyetylamine*, m.p. 42—43.5°; *tristearylamine*, m.p. 54—55°. H. W.

**Possible rearrangement reactions of monochloroamine and Grignard reagents.** G. H. COLEMAN and R. A. FORRESTER (J. Amer. Chem. Soc., 1936, 58, 27—28).—CH<sub>2</sub>Ph·MgCl and NH<sub>2</sub>Cl give 92% of CH<sub>2</sub>Ph·NH<sub>2</sub>;  $\alpha$ -C<sub>10</sub>H<sub>7</sub>·CH<sub>2</sub>·MgCl affords 47% of  $\alpha$ -C<sub>10</sub>H<sub>7</sub>·CH<sub>2</sub>·NH<sub>2</sub>; CHPh·CH·CH<sub>2</sub>·MgCl (at -20°) yields 14% of CHPh·CH·CH<sub>2</sub>·NH<sub>2</sub>. No indication of the formation of rearrangement products (viz., *o*-C<sub>6</sub>H<sub>4</sub>Me·NH<sub>2</sub>, 1:2-C<sub>10</sub>H<sub>6</sub>Me·NH<sub>2</sub>, and NH<sub>2</sub>·CHPh·CH·CH<sub>2</sub>, respectively) was obtained. H. B.

**Kinetics of ring formation and polymerisation in solution.**—See this vol., 296.

**Reduction of organic compounds by ethanolamines.** M. MELTSNER, C. WOHLBERG, and M. J. KLEINER (J. Amer. Chem. Soc., 1935, 57, 2554).—Reduction of anthraquinone, (NPh)<sub>2</sub>, and COMe<sub>2</sub> occurs when these are heated with N(CH<sub>2</sub>·CH<sub>2</sub>·OH)<sub>3</sub> (I); anthranol, NH<sub>2</sub>Ph, and Pr<sup>2</sup>OH, respectively, are formed. Mixtures of the azo-, azoxy- (II), and NH<sub>2</sub>-derivatives are similarly produced from PhNO<sub>2</sub> and *o*-C<sub>6</sub>H<sub>4</sub>Me·NO<sub>2</sub> with (I), NH<sub>2</sub>·CH<sub>2</sub>·CH<sub>2</sub>·OH, or, preferably, NH(CH<sub>2</sub>·CH<sub>2</sub>·OH)<sub>2</sub> in presence of aq. NaOH; (II) is not formed in absence of NaOH. Chrysoidine is reduced [? by (I)] to 1:2:4-C<sub>6</sub>H<sub>3</sub>(NH<sub>2</sub>)<sub>3</sub>. Aq. solutions of Ag, Pb, Hg, and other metal salts are also reduced. H. B.

**Mixed molybdates.**—See this vol., 302.

**[Derivatives of] ruthenium-red.**—See this vol., 302.

**Preparation and properties of  $\beta$ -*n*-alkylcholine chlorides and their acetyl esters.** R. T. MAJOR and H. T. BONNETT (J. Amer. Chem. Soc., 1936, 58, 22—24).—OH·CHR·CH<sub>2</sub>·NMe<sub>2</sub> (from OH·CHR·CH<sub>2</sub>Cl and NHMe<sub>2</sub> in C<sub>6</sub>H<sub>6</sub> at 115—120°) are converted (MeI followed by AgCl) into OH·CHR·CH<sub>2</sub>·NMe<sub>2</sub>Cl (R=Et—*n*-C<sub>7</sub>H<sub>15</sub>), which are acetylated (method:

A., 1932, 257) to  $\text{OAc}\cdot\text{CHR}\cdot\text{CH}_2\cdot\text{NMe}_3\text{Cl}$ . The following are described:  $\alpha$ -chlorononan- $\beta$ -ol, b.p. 114.5—116.5°/13 mm. (prep.: Levene and Haller, A., 1928, 737);  $\alpha$ -dimethylamino- $\beta$ -hydroxybutane, b.p. 142—144°/760 mm., -hexane, b.p. 89—90°/25 mm., -octane, b.p. 99—101°/10 mm., and -nonane, b.p. 104—106°/5 mm.;  $\beta$ -ethylcholine chloride, m.p. 174—176° (acetate, m.p. 144—146°), and iodide, m.p. 162—163°;  $\beta$ -n-propylcholine chloride, m.p. 115—117° (acetate, m.p. 168—169°), and iodide, m.p. 198—200°;  $\beta$ -n-butylcholine chloride, m.p. 100.5—102° (acetate, m.p. 186—187°), and iodide, m.p. 90—92°;  $\beta$ -n-amylcholine chloride, m.p. 72—74° (acetate, m.p. 182—184°), and iodide, m.p. 98—100° (lit. 106—108°);  $\beta$ -n-hexylcholine chloride, m.p. 69—71° (acetate, m.p. 169—171°), and iodide, m.p. 109—110°;  $\beta$ -n-heptylcholine chloride, m.p. 97—99° (acetate, m.p. 176—177°), and iodide, m.p. 122.5—123.5°. Pharmacological data are given; none of the acetates is as active as  $\text{OAc}\cdot\text{CHMe}\cdot\text{CH}_2\cdot\text{NMe}_3\text{Cl}$  (cf. Simonart, A., 1932, 1284).

H. B.

**Equilibrium of amino-acids, carbon dioxide, and carbamates in aqueous solution.**—See this vol., 289.

**Feeding experiments with purified amino-acids.** VIII.—See this vol., 233.

**Synthesis of  $\alpha$ -amino- $\beta$ -hydroxy- $n$ -butyric acids.** H. E. CARTER (J. Biol. Chem., 1936, 112, 769—773).—The mixture of isomerides,  $\text{OH}\cdot\text{CHMe}\cdot\text{CH}(\text{NH}_2)\cdot\text{CO}_2\text{H}$  (I), of Abderhalden *et al.* (A., 1934, 638) has no physiological activity. Formylation gives  $\alpha$ -formamido- $\beta$ -methoxy- $n$ -butyric acid, m.p. 173—174°, which after epimerisation by hot  $\text{Ac}_2\text{O}$ -NaOH and hydrolysis with HBr yields a mixture of stereoisomerides of (I), which has about 25% of the activity of the natural acid.

R. S. C.

**Canavanine.** VI. M. KITAGAWA and A. TAKANI (J. Agric. Chem. Soc. Japan, 1935, 11, 1077—1082).—The similarity in properties of  $\text{ONH}_2\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$  and canaline confirms the structure of  $\text{ONH}_2\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{CH}(\text{NH}_2)\cdot\text{CO}_2\text{H}$ . Guanidation of  $\alpha$ -benzoylcanaline with methylisocarbamide followed by hydrolysis yields (as flavianate) canavanine, which therefore is  $\text{NH}_2\cdot\text{C}(\text{NH})\cdot\text{N}(\text{OH})\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{CH}(\text{NH}_2)\cdot\text{CO}_2\text{H}$  (cf. A., 1934, 993).

F. O. H.

**Specific rotation of *l*-cystine in relation to degree of neutralisation and  $p_H$ .** G. TOENNIES, T. F. LAVINE, and (MISS) M. A. BENNETT (J. Biol. Chem., 1936, 112, 493—496).— $[\alpha]_{25}^{25}$  at  $p_H$  0—10.6 are recorded for 0.005*M*-*l*-cystine, prepared from 98—99% pure Li cystinate by adding varying amounts of LiOH and/or HCl.  $[\alpha]_{H_2O}$  is  $-225^\circ$  at  $p_H$  about 0.1,  $-97^\circ$  at  $p_H$  11.6, and  $-325^\circ$  at  $p_H$  3—7 (the isoelectric range).  $d[\alpha]/dt$  is  $+1.5^\circ$  between 19.3° and 32.05°.

R. S. C.

**New synthesis of methionine and a scheme relating certain  $\alpha$ -amino-acids.** E. M. HILL and W. ROBSON (Biochem. J., 1936, 30, 248—251).—*Et*  $\gamma$ -chloro- $\alpha$ -benzamidobutyrate, m.p. 45°, prepared by treatment of  $\alpha$ -benzamido- $\gamma$ -butyrolactone with HCl in EtOH, gave benzoylmethionine on treatment with NaSMe and subsequent alkaline hydrolysis.

Acid hydrolysis gave methionine (carbamide, m.p. 171—172°; hydantoin, m.p. 117—118°). H. D.

**Determination of the stereochemical purity of *l*-cysteine.** G. TOENNIES and (MISS) M. A. BENNETT (J. Biol. Chem., 1936, 112, 497—502).—*l*-Cysteine (modified prep.),  $[\alpha]_{D}^{20} + 9.68 \pm 0.05^\circ$ ,  $[\alpha]_{D}^{15} + 7.6 \pm 0.1^\circ$  (*M* solution in *N*-HCl;  $d\alpha/dt = -1\%$  between 23° and 33°), is determined within  $\pm 0.25\%$  by oxidation with  $\text{H}_2\text{O}_2$  (2% excess) in *N*-HCl in presence of 0.003*M*- $\text{CuSO}_4$  and determination of the max.  $[\alpha]$  (due to cystine) during 1 hr.

R. S. C.

**Detection of cysteine in presence of cystine.** C. B. DI CAPUA (Boll. Soc. ital. Biol. speriment., 1935, 10, 428—429).—Grothe's reagent can be used for detection of cysteine, but the supposed blue cystine (I) coloration appears in acid solution without (I) and is probably due to formation of Prussian-blue.

R. N. C.

**Highly polymerised compounds. CXXIV.** Measurements of the viscosity of amides and anilides of fatty acids. H. STAUDINGER and K. ROSSLER (Ber., 1936, 69, [B], 61—73).—The m.p. of the normal fatty amides is considerably  $>$  that of the corresponding acids; the lower m.p. of *sec.*- and *tert.*-amides may be caused by the presence of branched chains. Correspondingly the methylamides and more particularly the dimethylamides are more freely sol. in  $\text{C}_6\text{H}_6$ ,  $\text{CCl}_4$ , or  $\text{CHCl}_3$  than the simple amides. The relatively high m.p. of primary amides depends on peculiarities of structure as well as on the formation of co-ordinative mols. Measurements of  $\eta_{sp}$ , dimethylamides in  $\text{C}_6\text{H}_6$  gives vals.  $>$  expected, which do not depend on concn. Since the temp. effect is normal the  $\text{CO}\cdot\text{NH}_2$  group causes exaltation; this view is confirmed by the behaviour of the piperidides. Similarly,  $\eta_{sp}$  of amides and methylamides in  $\text{CHCl}_3$  is  $>$  expected. Methylanilides in  $\text{C}_6\text{H}_6$ ,  $\text{CCl}_4$ , or  $\text{CHCl}_3$  behave similarly to the dimethylamides. On the hypothesis that mols. in solution assume the longest possible form, the normal mols. of anilides have

the structure  $\text{Me}\cdot[\text{CH}_2]_n\cdot\overset{\text{O}}{\text{C}}\cdot\text{NHPh}$ . Co-ordinative mols. can have the structure  $\text{Me}\cdot[\text{CH}_2]_n\cdot\text{C}(\text{O})\cdot\text{NH}\cdot\text{Ph}\cdot\text{HN}(\text{O})\text{C}(\text{O})\cdot[\text{CH}_2]_n\cdot\text{Me}$  or

$\text{PhNH}\cdot\text{COR}\cdot\text{HN}\cdot\text{Ph}\cdot\text{COR}$  dependent on whether or not

$\text{Me}\cdot[\text{CH}_2]_n\cdot\text{CO}$  is longer than Ph. Support for this view is found in the observation that the m.p. of fatty acid anilides passes through a min. at octoanilide.  $\eta_{sp}$  of anilides in  $\text{C}_6\text{H}_6$ ,  $\text{CHCl}_3$ , or  $\text{C}_5\text{H}_5\text{N}$  shows progression similar to that of the m.p. In AcOH the viscosity of anilides appears to depend on the ionogenic groups rather than on the chain length. The following compounds are incidentally described. *methylamides* of undecenoic, myristic (I), and palmitic (II) acid, m.p. 48—49°, 78—79°, and 86°, respectively; *dimethylamides* of lauric (III), (I), (II), and stearic acid (IV), b.p. 180°/15 mm., m.p. 18—20°, b.p. 210—213°/15 mm., m.p. 31—32°, m.p. 41° and m.p. 50—51.5°, respectively; *stearyl* piperidide, m.p. 37—38°; *methylanilides* of (III), (I), (II), and (IV), b.p. 1°/0.2 mm., m.p. 15°, b.p. 204.5—206°/0.5 mm., m.p.

29–30°, b.p. 202–203°/0.01 mm., m.p. 40–45° and m.p. 48.5–49.5°, respectively. H. W.

**Condensation of carbamide and formaldehyde.** G. WALTER (Trans. Faraday Soc., 1936, 32, 377–395).—A summary of work previously published (cf. B., 1931, 357; A., 1932, 150). F. L. U.

**Coloured compound formed in Sullivan reaction for guanidine.** M. X. SULLIVAN and W. C. HESS (J. Amer. Chem. Soc., 1936, 58, 47–48; cf. this vol., 195).—The compound, decomp. about 250°, formed from guanidine (I) and Na 1:2-naphthaquinone-4-sulphonate in aq. NaOH at 90°, followed by acidification (conc. HCl+conc. HNO<sub>3</sub>), is considered to be (II) since it is hydrolysed (conc. H<sub>2</sub>SO<sub>4</sub>, 95% EtOH) to 2-hydroxy-1:4-naphthaquinone. (II) is

rose-coloured in acid, purple in alkali, and forms NH<sub>4</sub>, m.p. 285–288°, and Na, m.p. 297–300°, salts. 1:2-Naphthaquinone, (I), and a little HNO<sub>3</sub> in aq. EtOH give the compound, 1:2-O:C<sub>10</sub>H<sub>6</sub>:N·C(NH)·NH<sub>2</sub>, m.p. 265–267° (decomp.), hydrolysed (20% HCl) to α-C<sub>10</sub>H<sub>7</sub>·OH. H. B.

**Reduction of nitroguanidine. II. Preparation and properties of nitrosoguanidine.** V. J. SABETTA, D. HIMMELFARB, and G. B. L. SMITH. III. **Synthesis of aminoguanidine.** G. B. L. SMITH and E. ANZELMI. IV. **Preparation of nitrosoguanidine by catalytic hydrogenation** [of nitroguanidine]. E. LIEBER and G. B. L. SMITH (J. Amer. Chem. Soc., 1935, 57, 2478–2479, 2730, 2739–2480).—II. Slightly impure nitrosoguanidine (I), detonates at 161°, is obtained in 40–60% yield by reduction (Zn dust and aq. NH<sub>4</sub>Cl at < 50°) of nitroguanidine (II). Methods for the determination of (I) are given.

Methylisothiocarbamidesulphate and N<sub>2</sub>H<sub>4</sub>·H<sub>2</sub>O give MeSH and the sulphate (yield 90%) of aminoguanidine (*K<sub>b</sub>* 1.1 × 10<sup>-3</sup>), the H carbonate of which is CH<sub>6</sub>N<sub>4</sub>·H<sub>2</sub>CO<sub>3</sub>.

1. Reduction [H<sub>2</sub> (slightly > 1 mol.), PtO<sub>2</sub> or Raney Ni, H<sub>2</sub>O] of (II) affords 36–62% of (I).

**Vinyldiazomethane.** C. D. HURD and S. C. LUI (J. Amer. Chem. Soc., 1935, 57, 2656–2657).—Vinyldiazomethane (I), obtained from nitrosoallylurethane (m.p. 110°, prep.) by Nirdlinger and Acree's method (A., 1910, i, 341), with BzOH gives allyl benzoate. Appreciable isomerisation of (I) to pyrazole (cf. Adamson and Turner, A., 1935, 479) occurs during its distillation. H. B.

**Parachor and molecular refraction of hydrazine and its aliphatic derivatives.**—See this vol., 279.

**Dibutylphosphorous acid chloride and preparation of butylpyrophosphorous acid from it.** BUSOV and V. S. ABRAMOV (Trans. Butlerov Inst. Chem. Tech. Kazan, 1934, No. 1, 28–33).—

BuO·PCl<sub>2</sub> is converted by NaOBu into (BuO)<sub>2</sub>PCl<sub>2</sub>; this, with (BuO)<sub>2</sub>P·ONa, affords *butylpyrophosphorous acid*, b.p. 175–176°, which, with H<sub>2</sub>O, yields (BuO)<sub>2</sub>P·OH, and, with Br, a Br<sub>4</sub>-compound.

CH. ABS. (r)

**Acetoacetic acid O-phosphoric ester.** P. KARRER and H. BENDAS (Helv. Chim. Acta, 1936, 19, 98–99).—Cautious treatment of ONa·CHMe·CH·CO<sub>2</sub>Et with POCl<sub>3</sub> give *Et<sub>3</sub> acetoacetate O-phosphate*, isolated as the salt PO<sub>3</sub>Ba·O·CMe·CH·CO<sub>2</sub>Et. The corresponding Na<sub>2</sub> salt is hydrolysed to the compound (I), PO<sub>3</sub>Na<sub>2</sub>·O·CMe·CH·CO<sub>2</sub>Na. Hot, dil. acids convert (I) into CH<sub>2</sub>Ac·CO<sub>2</sub>H or COMe<sub>2</sub>; kidney phosphatase readily removes ·OPO<sub>3</sub>Na<sub>2</sub> from (I) at *p<sub>H</sub>* 9. H. W.

**Phosphate transferences by means of phosphopyruvic acid in alcoholic fermentation of sugar.**—See this vol., 246.

**Preparation of boron alkoxy-halides and their reaction with metals.** C. R. KINNEY, H. T. THOMPSON, and L. C. CHENEY (J. Amer. Chem. Soc., 1935, 57, 2396–2397).—A mixture of triisomyl borate (I) (2 mols.) and BCl<sub>3</sub> (1 mol.) is kept for 24 hr. and then fractionated; *B diisomylloxy-chloride* (II), b.p. 110–115°/14 mm., is obtained in 45% yield. (II) and Na in C<sub>6</sub>H<sub>6</sub> at 70° give HCl, isopentene, H<sub>2</sub>, (I), and B<sub>2</sub>O<sub>3</sub>. BCl(OEt)<sub>2</sub> warmed with Na or Zn dust similarly affords B(OEt)<sub>3</sub> and B<sub>2</sub>O<sub>3</sub>. H. B.

**Colour reaction for detection of cyclopentadiene.** B. N. AFANASIEV (Ind. Eng. Chem. [Anal.], 1936, 8, 15).—A violet colour is produced when one drop of cyclopentadiene dissolved in CHCl<sub>3</sub> (1 c.c.) and AcOH (1 c.c.) is treated with conc. H<sub>2</sub>SO<sub>4</sub>. A similar coloration is obtained with higher terpenes but only when Ac<sub>2</sub>O is used. S. C.

**Ozonisation of hydrogenated diphenyls.** C. R. NOLLER and G. K. KANEKO (J. Amer. Chem. Soc., 1935, 57, 2442–2443).—1-Phenyl-Δ<sup>1:1</sup>-cyclohexene (I) and di-Δ<sup>1:1</sup>-cyclohexenyl add 1 and 2 mols., respectively, of O<sub>3</sub>, indicating that steric hindrance in the 1 and 1' positions is not the factor involved in the failure of Ph<sub>2</sub> to give a hexaozonide (cf. Harries and Weiss, A., 1906, i, 228). Decomp. of the ozonides affords δ-benzoylvaleric and adipic acid, respectively. The tetrahydrodiphenyl obtained (cf. Bamberger and Lodter, A., 1888, 292) by reduction (Na, amyl alcohol) of Ph<sub>2</sub> is mainly (I). H. B.

**Dehydration of benzylcyclohexanols.** J. W. COOK and C. L. HEWETT (J.C.S., 1936, 62–71).—2-Methylcyclohexanone and CH<sub>2</sub>Ph·MgCl (I) give impure 1-benzyl-2-methylcyclohexanol, b.p. 115°/0.8 mm., dehydrated (KHSO<sub>4</sub> at 160–175°) to 1-benzyl-2-methyl-Δ<sup>1</sup>-cyclohexene, b.p. 158–160°/19 mm., converted by AlCl<sub>3</sub> in CS<sub>2</sub> at 0° into a saturated hydrocarbon, C<sub>14</sub>H<sub>18</sub>, b.p. 141°/18 mm., which could not be dehydrogenated (Se at 300–320°; Pd-C at 300°) and is oxidised (dil. HNO<sub>3</sub> at 180–185°) to α-C<sub>6</sub>H<sub>4</sub>(CO<sub>2</sub>H)<sub>2</sub>. Tetrahydrocarvone and (I) afford 1-benzyl-2-methyl-5-isopropylcyclohexanol, b.p. 140–142°/0.6 mm., dehydrated (ZnCl<sub>2</sub> at 160°) to 1-benzyl-2-methyl-5-isopropyl-Δ<sup>1</sup>-cyclohexene, b.p. 159°/12 mm., similarly converted into a saturated hydrocarbon, C<sub>17</sub>H<sub>24</sub>, b.p. 160–161°/13 mm., which could

not be dehydrogenated. Phenylcyclohexylcarbinol (II) and 1- (III) and 2-benzylcyclohexanol, b.p. 154°/11 mm., m.p. 75.5—76° (prepared by reduction of the hexanone with Na and H<sub>2</sub>O in Et<sub>2</sub>O), are all converted by P<sub>2</sub>O<sub>5</sub> at 150° into 30—70% of 2:3-benz-1:3:3-dicyclo-Δ<sup>2</sup>-nonene (IV), b.p. 85°/0.3 mm., 123°/15 mm., and not (XII) (below) (see A., 1933, 1042); (IV) is oxidised (dil. HNO<sub>3</sub> at 180°) to *o*-C<sub>6</sub>H<sub>4</sub>(CO<sub>2</sub>H)<sub>2</sub>, thus showing that cyclisation involves the attachment of the alicyclic part of the mol. at C2 of the C<sub>6</sub>H<sub>6</sub> ring.

(IV) could not be dehydrogenated (Pt-black or -asbestos); it is oxidised (Na<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>, AcOH) to 2:3-benz-1:3:3-dicyclo-Δ<sup>2</sup>-nonen-4-one (V), b.p. 108—110°/0.2 mm. (oxime, m.p. 123—124°; semicarbazone, m.p. 222—224°), which is reduced (Clemmensen) to pure (IV). The complete absence of strain in (IV) is probably the determining factor in its formation. (V) and HNO<sub>3</sub> (*d* 1.5) give the 3'-NO<sub>2</sub>-derivative, m.p. 118.5—119.5°, reduced (SnCl<sub>2</sub>, conc. HCl, EtOH) to the 3'-NH<sub>2</sub>-derivative, m.p. 122.5—123.5°, which is oxidised (CrO<sub>3</sub>, AcOH) to *cis*-hexahydrosophthalic acid (VI) and converted (through the diazonium sulphate) into 3'-hydroxy-2:3-benz-1:3:3-dicyclo-Δ<sup>2</sup>-nonen-4-one, m.p. 160.5—161.5° [oxidised (KMnO<sub>4</sub>, aq. KOH) to (VI)]. (V) could not be methylated (MeI, NaNH<sub>2</sub>). No reaction occurs between (V) and Br in CS<sub>2</sub>, indicating the absence of enol.

1-Benzyl-Δ<sup>1</sup>-cyclohexene (VII), obtained (cf. von Auwers and Treppmann, A., 1915, i, 789; Prévost *et al.*, A., 1934, 649) by dehydration (KHSO<sub>4</sub>) of (III), is converted into the nitrosochloride, m.p. 116—117° (lit. 110°), and thence by boiling C<sub>5</sub>H<sub>5</sub>N into 2-benzyl-Δ<sup>2</sup>-cyclohexenoneoxime, m.p. 138.5—139.5° (lit. 136—138°), which when hydrolysed (6*N*-H<sub>2</sub>SO<sub>4</sub>) and then reduced (H<sub>2</sub>, Pd-black, Et<sub>2</sub>O) gives 2-benzylcyclohexanone (VIII). Dehydration (ZnCl<sub>2</sub> at 170—180°) of (II) affords a mixture of (IV) [proved by oxidation to (V)] and unsaturated material, which is not (VII) (cf. von Auwers, this vol., 195) but may be benzylidenecyclohexane. Contrary to von Auwers and Treppmann (*loc. cit.*), there is no evidence of the change CHPh:C< CH<sub>2</sub>Ph:C<. *Et*-2-benzylcyclohexanone-2-carboxylate, b.p. 144—145°/0.4 mm., m.p. 34.5—35° (semicarbazone, m.p. 182—183°), prepared from *Et* sodiocyclohexanone-2-carboxylate and CH<sub>2</sub>PhCl in C<sub>6</sub>H<sub>6</sub>, is hydrolysed (EtOH-KOH) to *α*-benzylpimelic acid, m.p. 81—82°, which when distilled (from bath at 360—380°) gives (VIII). *trans*-2-Ketodecahydronaphthalene and (I) give β-decahydronaphthylbenzylcarbinol, b.p. 171°/6 mm. (3:5-dinitrobenzoate, m.p. 162.5—164°), dehydrated (KHSO<sub>4</sub> at 160—170°) to 2-benzyldecahydronaphthalene, b.p. 151°/6 mm., which is reduced (H<sub>2</sub>, Pd-black, AcOH) to 2-benzyldecahydronaphthalene (IX), b.p. 173—175°/10 mm., and dehydrogenated (Se at 310—320°) to 2-benzyldecahydronaphthalene [also formed from (IX) and Pt-black at 300—305° but not with Se at 320—330°]. Successive oxidation (CrO<sub>3</sub>, cold AcOH) and reduction (H<sub>2</sub>, Pd-black, AcOH) of 2-phenyl-Δ<sup>3</sup>-tetrahydrobenzaldehyde (Lehmann and Paasche, A., 1935, 978) gives 2-phenylhexahydro-

benzoic acid (X), m.p. 105—107°, better prepared by reduction (Na, amyl alcohol) of *o*-C<sub>6</sub>H<sub>4</sub>Ph-CO<sub>2</sub>H [the acid obtained by catalytic reduction (Raneco and León, A., 1925, i, 665) is not a stereoisomeride of (X) but is *o*-cyclohexylbenzoic acid, m.p. 104°, oxidised (alkaline KMnO<sub>4</sub>) to *o*-C<sub>6</sub>H<sub>4</sub>(CO<sub>2</sub>H)<sub>2</sub>]. The chloride of (X) with AlCl<sub>3</sub> in CS<sub>2</sub> at 0° affords 1:2:3:4:10:11-hexahydrofluorenone (XI), m.p. 41.5—42° (oxime, m.p. 183—185°; semicarbazone, m.p. 212—213°), reduced (Clemmensen) to 1:2:3:4:10:11-hexahydrofluorene (XII), b.p. 127°/15 mm., which is readily dehydrogenated (Se at 300—320°; Pt at 250—260°) to fluorene. Oxidation (CrO<sub>3</sub>, AcOH) of (XII) gives resinous products but no (XI). The hexahydrofluorenone of Vocke (A., 1934, 189) is probably (XI). Reduction of fluorenone-oxime by Nakamura's method (A., 1930, 466) gives fluorene and a base; (XII) is not formed. H. B.

Tables of the number of isomerides of the simpler derivatives of cyclic parents. G. PÓLYA (Helv. Chim. Acta, 1936, 19, 22—24).—The no. of structural isomerides (not stereoisomerides) is tabulated which can be derived by replacement of H of C<sub>6</sub>H<sub>6</sub>, C<sub>10</sub>H<sub>8</sub> (anthraquinone), anthracene (pyrene), phenanthrene or thiophen (furan) by the univalent radicals X, Y, and Z provided that the introduction of X<sub>a</sub>, Y<sub>b</sub>, and Z<sub>c</sub> into the parent does not lead to the same mol. formula as the introduction of X<sub>b</sub>, Y<sub>k</sub>, and Z<sub>l</sub>. The case of alkyl derivatives receives extended treatment. H. W.

#### Kinetics of nitration of aromatic compounds.

—See this vol., 297.

#### Direct introduction of deuterium into benzene.

—See this vol., 299.

Reaction of paraffins with aromatic hydrocarbons (destructive alkylation). A. V. GROSSE and V. N. IPATIEV (J. Amer. Chem. Soc., 1935, 57, 2415—2419; cf. A., 1935, 1348).—In presence of suitable catalysts paraffins and aromatic hydrocarbons react thus: C<sub>(m+n)</sub>H<sub>2(m+n)+2</sub> + ArH > C<sub>n</sub>H<sub>2n+2</sub>. Ar·C<sub>m</sub>H<sub>2m+1</sub>. Dry HCl is passed through ββ-trimethylpentane (I), C<sub>6</sub>H<sub>6</sub>, and AlCl<sub>3</sub> at 25—50° (or ZrCl<sub>4</sub> at 50—75°); isobutane, PhBu<sup>+</sup>, and C<sub>6</sub>H<sub>4</sub>Bu<sup>+</sup> (only the *p*-compound is isolated pure) [formed by further reaction of PhBu<sup>+</sup> with (I)] are produced. (I) and C<sub>6</sub>H<sub>6</sub> do not react in presence of MgCl<sub>2</sub>-HCl at 200°/20 atm. or BF<sub>3</sub> (promoted by Ni and H<sub>2</sub>O) at 55°. H. B.

Kinetics of Friedel-Crafts reaction and activity of mixed catalysts in the reaction of benzoyl chloride with toluene. L. F. MARTIN, P. PIZZOLATO, and L. S. McWATERS (J. Amer. Chem. Soc., 1935, 57, 2584—2589).—The reaction between Phale and BzCl in presence of AlCl<sub>3</sub>, FeCl<sub>3</sub>, and mixtures (I) of AlCl<sub>3</sub> and FeCl<sub>3</sub> is investigated using Steele's method (J.C.S., 1903, 83, 1470). All the (I) are more active than either of the components; the velocity coeff. increases with rise in the % of FeCl<sub>3</sub> and is max. with > 50 mols.-% in (I). For each mol. of total metal chlorides used, < 1 mol. of C<sub>6</sub>H<sub>5</sub>·C<sub>6</sub>H<sub>4</sub>· is produced; evidence showing that this is due to the removal of the catalyst as the complex,

COPh·C<sub>6</sub>H<sub>4</sub>Me, AlCl<sub>3</sub>, FeCl<sub>3</sub>, is given. The variation of the velocity coeff. with concn. is of the same order as that found by Olivier (A., 1918, i, 228) for the reaction between C<sub>6</sub>H<sub>6</sub> and BzCl. The velocity coeff. for the reaction between PhMe and CH<sub>2</sub>PhCl is greatly increased by a small % of FeCl<sub>3</sub>; a subsequent decrease occurs when substantial amounts are present. The results support the reaction mechanism proposed by Steele (*loc. cit.*). H. B.

**Decomposition of di-*o*-tolylidonium iodide.** H. J. LUCAS, E. R. KENNEDY, and C. A. WILMOT (J. Amer. Chem. Soc., 1936, 58, 157—160).—*o*-C<sub>6</sub>H<sub>4</sub>Me·IO, *o*-C<sub>6</sub>H<sub>4</sub>Me·IO<sub>2</sub>, and Ag<sub>2</sub>O [which catalyses the reaction C<sub>7</sub>H<sub>7</sub>IO + C<sub>7</sub>H<sub>7</sub>IO<sub>2</sub> → (C<sub>7</sub>H<sub>7</sub>)<sub>2</sub>I<sup>+</sup> + IO<sub>3</sub><sup>-</sup>] are triturated in CHCl<sub>3</sub> + successive small amounts of H<sub>2</sub>O; treatment of the combined aq. extracts with SO<sub>2</sub> or KI gives di-*o*-tolylidonium iodide (I). Decomp. of (I) at 155° (bath) affords only *o*-C<sub>6</sub>H<sub>4</sub>MeI (which is converted into *o*-C<sub>6</sub>H<sub>4</sub>Me·MgI and thence into *o*-C<sub>6</sub>H<sub>4</sub>Me·CO<sub>2</sub>H) : (*o*-C<sub>6</sub>H<sub>4</sub>Me)<sub>2</sub>I·I → *o*-C<sub>6</sub>H<sub>4</sub>MeI + *o*-C<sub>6</sub>H<sub>4</sub>Me<sup>+</sup> + I<sup>-</sup>. Physical data for the C<sub>6</sub>H<sub>4</sub>MeI are given. H. B.

**Chloro-derivatives of xylene.** H. WAHL (Ann Chim., 1936, [xi], 5, 5—82).—Partly a detailed account of work already reported (A., 1933, 815; 1934, 177, 181, 772, 878; 1935, 739). The following is new. Chloro-*p*-xylene (I) and H<sub>2</sub>SO<sub>4</sub> give 2-chloro-*p*-xylene-5-sulphonic acid, +2H<sub>2</sub>O, m.p. about 100° (a, +H<sub>2</sub>O, and Ca salts, +3H<sub>2</sub>O; chloride, m.p. 50; amide, m.p. 185°; anilide, m.p. 155°), obtained (diazo-reaction) also from *p*-xylylene-5-sulphonic acid and converted by HNO<sub>3</sub>—H<sub>2</sub>SO<sub>4</sub> at 50—60° into a mixture of 65—70% of 2-chloro-3-nitro-*p*-xylene-5-sulphonic acid (K, Ca, +4H<sub>2</sub>O, and Na, +2H<sub>2</sub>O, m.p. 101°) and 20% of 2-chloro-3:5-dinitro-*p*-xylene (II), m.p. 95° [also obtained from 2-chloro-3- and -5-nitro-*p*-xylene and HNO<sub>3</sub> at about 10° and (diazo-reaction) from 3:5-dinitro-*p*-xylylene]. Reduction (Fe—HCl) affords 3-chloro-*p*-xylylene-6-sulphonic acid, +H<sub>2</sub>O. The prep. of the 3-NO<sub>2</sub>, m.p. 36° (Ac derivative, m.p. 190°), and 5-NO<sub>2</sub>-derivatives of acet-*p*-xylylene is described. The third aldehyde (phenylhydrazone, m.p. 145°), obtained by nitration of (I), has m.p. 101°. 2-Chloro-6-nitro-*p*-xylene and HNO<sub>3</sub> at about 10° give 2-chloro-5:6-dinitro-*p*-xylene, m.p. 101°, reduced by Zn and AcOH—EtOH to the (NH<sub>2</sub>)<sub>2</sub>-compound, m.p. 50°, which affords a phenanthrazine, m.p. 235°. 5-Chloroacet-*p*-xylylene (III) and HNO<sub>3</sub> give 5-chloro-3-nitroacet-*p*-xylylene, m.p. 200—200·5°, hydrolysed (H<sub>2</sub>SO<sub>4</sub>) to 5-chloro-3-nitro-*p*-xylylene, m.p. 100—101° (Bz derivative, m.p. 160°), the structure of which is proved by conversion into 2-chloro-6-nitro-*p*-xylene. The Cl of the chloronitro-*p*-xylenes is unreactive owing to steric hindrance. The K salts, +H<sub>2</sub>O, of 2:3- and 2:6-dichloro-*p*-xylenesulphonic acids are described. 2:5-Dichloro-*p*-xylene and HNO<sub>3</sub> give the 6-NO<sub>2</sub>-derivative, m.p. 95°, b.p. 155—160°/15 mm., reduced (Fe) to the 6-NH<sub>2</sub>-derivative, m.p. 81°, b.p. 155—160°/15 mm. (Ac, m.p. 198°, and Bz derivative, m.p. 205°). (III) and Cl<sub>2</sub> in AcOH give 3:5-dichloroacet-*p*-xylylene, m.p. 172°, hydrolysed to the base, m.p. 48°, b.p. 160—162°/15 mm. (Bz derivative, m.p. 179—180°), which (diazo-reaction) yields 2:6-dichloro-*p*-xylene. *p*-Xylylene with Cl<sub>2</sub> in conc.

H<sub>2</sub>SO<sub>4</sub> at about 40° affords the 5:6-Cl<sub>2</sub>-derivative, m.p. 78—80°, b.p. 165—170°/15 mm. [Ac, m.p. 165° (corr.), and Bz derivative, m.p. 173° (corr.)], converted (diazo-reaction) into 2:3-dichloro-*p*-xylene. Hot chlorination of (III) affords 3:5:6-trichloroacet-*p*-xylylene, m.p. 220°, and thence the base, m.p. 206°. Dyes obtained by coupling each of 10 diazotised xylylenes with 9 2-hydroxy-1-naphthxylylenes and 9 naphthols are described. The fastness of these dyes to light, Cl<sub>2</sub>, and washing is good. The following are prepared: 2-hydroxy-1-naphth-xylylene, m.p. 200°, -3-, m.p. 230°, -5'-, m.p. 258°, and -6'-chloro-, m.p. 180°, -3'-, m.p. 150° (decomp.), -5'-, m.p. 255° (decomp.), and -6'-nitro-, m.p. 145°, and -3':5'-, m.p. 223°, -3':6'-, m.p. 250°, and -5':6'-dichloro-*p*-xylylene, m.p. 233°. R. S. C.

**Jacobsen reaction.** IV. L. I. SMITH and C. L. MOYLE (J. Amer. Chem. Soc., 1936, 58, 1—10).—The Jacobsen rearrangement is not a general reaction; it is limited (with few exceptions) to C<sub>6</sub>H<sub>5</sub>Me<sub>3</sub>, C<sub>6</sub>HMe<sub>5</sub>, C<sub>6</sub>HMe<sub>4</sub>Et, and halogeno-derivatives of C<sub>6</sub>H<sub>5</sub> and methylbenzenes. Labile groups are Cl, Br, I, Me, Et, and SO<sub>3</sub>H; no rearrangement occurs when NO<sub>2</sub>, Ac, OMe, or CO<sub>2</sub>H is present. In general, except when Hal is present, < 4 substituents must be in the C<sub>6</sub>H<sub>5</sub> nucleus to obtain rearrangement; the course (and ease) of the reaction is determined by the substituents. Results now and previously obtained (A., 1933, 600) show that for all the C<sub>6</sub>HMe<sub>4</sub>Cl and C<sub>6</sub>HMe<sub>4</sub>Br, the ease of migration is Br > Me > Cl, whilst for C<sub>6</sub>H<sub>3</sub>Me<sub>3</sub>Cl and C<sub>6</sub>H<sub>2</sub>Me<sub>3</sub>Br the order is Br > Cl > Me (when rearrangement occurs). There appears to be some correlation between the ease of hydrolysis of ArSO<sub>3</sub>H and its ability to undergo rearrangement. Whenever rearrangement occurs, side reactions leading to amorphous solids or tars and SO<sub>2</sub> also occur. Attempts to rearrange C<sub>6</sub>Me<sub>5</sub>·SO<sub>3</sub>H, using conditions designed to avoid such reactions, failed; rearrangement could not be effected with reagents [e.g., PhSO<sub>3</sub>H, H<sub>3</sub>PO<sub>4</sub>, CaCl<sub>2</sub>, Mg(ClO<sub>4</sub>)<sub>2</sub>] other than H<sub>2</sub>SO<sub>4</sub>. The constitutions of the compounds described below are established by conversion into known or proved derivatives.

Chlorodurene (from durene and Cl<sub>2</sub> in CHCl<sub>3</sub> at 0° and conc. H<sub>2</sub>SO<sub>4</sub> at 65° give 99% of chloropentamethylbenzene (I), m.p. 154·5—155° [reduced (red P, 45% HI, 220°) to C<sub>6</sub>HMe<sub>5</sub>], and 81% of 3-chloro-*ψ*-cumene-5-sulphonic acid (II) [also prepared by short treatment of 3-chloro-*ψ*-cumene (III) with oleum]. Chlorosodurene, b.p. 139°/41 mm., m.p. -1° to 1° (obtained with a little of the Cl<sub>2</sub>-derivative, m.p. 188°, from isodurene and Cl<sub>2</sub> in CHCl<sub>3</sub>), similarly affords (I) (96·4%), (II) (70%), and a little of a compound, C<sub>20</sub>H<sub>24</sub>Cl<sub>2</sub>, m.p. 209·5°, whilst chloroprehnitenene, b.p. 131—132°/24 mm., m.p. 24°, and approx. 14% oleum at 25—30° yield (I) (98%) and (II) [or, by hydrolysis, (III)]. At least two rearrangements are considered to occur with the above C<sub>6</sub>HMe<sub>4</sub>Cl. 5-Chloro-*ψ*-cumene, m.p. 70·5—71° [formed with (III) from *ψ*-cumene and Cl<sub>2</sub> in CHCl<sub>3</sub> at 0°, and 20% oleum at 65—70° give (II) (71%) and tar. (II) (44%) and a small amount of an unidentified product, m.p. 148—153°, are formed from 6-chloro-*ψ*-cumene (IV), b.p. 127—128°/20 mm. [3:5-(NO<sub>2</sub>)<sub>2</sub>-derivative, m.p.

162° (lit. 162° and 169—170°), and approx. 15% oleum at 25—30°. Intramol. migration of Cl thus occurs in both cases. (IV) is prepared by deamination of 6-chloro-5- $\psi$ -cumidine [from  $\psi$ -cumidine (V) (in EtOH-I) and  $\text{Cl}_2$  (in  $\text{CHCl}_3$ )]. Chloromesitylene [ $\text{SO}_3\text{H}$  derivative ( $\text{Na}$  salt +  $0.5\text{H}_2\text{O}$ ; *amide*, m.p. 165.5—166°)] and 4-chlorohemimellitene, b.p. 86—87°/16 mm. [5:6- $\text{Br}_2$ -derivative, m.p. 229—230°], prepared from hemimellitene and  $\text{Cl}_2$  in  $\text{CHCl}_3$ -I at 0°, do not rearrange; sulphonation occurs with 20% oleum at 70—75°. Bromomesitylene [ $\text{SO}_3\text{H}$  derivative ( $\text{Na}$  salt +  $0.5\text{H}_2\text{O}$ ; *amide*, m.p. 160—160.5°)] and 20% oleum at 25—30° give *dibromomesitylene*, m.p. 65.5°, and 2:4:6- $\text{C}_6\text{H}_3\text{Me}_3\text{SO}_3\text{H}$  (not isolated; hydrolysed to  $s\text{-C}_6\text{H}_3\text{Me}_3$ ); at 70°, *tribromomesitylene*, m.p. 223.5—224°, is formed in 68.5% yield. 5-Bromo- $\psi$ -cumene [from  $\psi$ -cumene-5-sulphonic acid (VI) and Br in aq. EtOH] and 20% oleum at 25—30°/6 weeks afford a little *tribromo- $\psi$ -cumene*, m.p. 232°, and 90% of 3-bromo- $\psi$ -cumene-5-sulphonic acid [ $\text{Na}$  salt, also prepared from the  $\text{Na}$  salt of (VI) in EtOH with Br in  $\text{CHCl}_3$ ], hydrolysed (dil.  $\text{H}_2\text{SO}_4$  at 145°) to 3-bromo- $\psi$ -cumene. The following compounds did not undergo any rearrangement when treated with conc.  $\text{H}_2\text{SO}_4$  or oleum: (V), hemimellitene, 5-nitro- $\psi$ -cumene, 2:3- $\text{C}_{10}\text{H}_6\text{Me}_2$ ,  $p\text{-C}_6\text{H}_4\text{PhBr}$ , pentamethylcyclohexane, b.p. 98—98.5°/38 mm., 188°/730 mm. [prepared by reduction ( $\text{H}_2$ , Ni-kieselguhr, 225°) of  $\text{C}_6\text{HMe}_5$ ], and *Me pentamethylbenzenesulphonate*, m.p. 91—91.5° (from  $\text{C}_6\text{Me}_5\text{SO}_2\text{Cl}$  and  $\text{MeOH-NaOMe}$ ).

Reduction (Zn, dil. HCl) of 3-chloro- $\psi$ -cumene-5-sulphonamide, m.p. 182°, affords  $\psi$ -cumene-5-sulphonamide, m.p. 180°.  $\text{Na}$  3-chloro- $\psi$ -cumene-5-sulphonate (VII) is reduced ( $\text{Na-Hg}$ ,  $\text{H}_2\text{O}$ ) to  $\text{Na}$   $\psi$ -cumene-5-sulphonate (nitrated to trinitro- $\psi$ -cumene, m.p. 183.5°), is converted by red P and 45% HI into  $\psi$ -cumene, and is hydrolysed (dil.  $\text{H}_2\text{SO}_4$  at 135—155°) to 3-chloro- $\psi$ -cumene, b.p. 127°/61 mm. [5:6-( $\text{NO}_2$ )<sub>2</sub>-derivative (VIII), m.p. 173.5—174°, also formed by nitration of (VII)]. 3-Chloro-5:6-diamino- $\psi$ -cumene, m.p. 136.5° [from (VIII),  $\text{SnCl}_2$ , and EtOH-conc. HCl], and phenanthraquinone (IX) in EtOH-AcOH afford 12-chloro-10:11:13-trimethylphenanthrophenazine, m.p. 330.5—331°, whilst reduction ( $\text{SnCl}_2$ , HCl) of (VIII) in AcOH gives 6-chloro-2:4:5:7-tetramethylbenziminazole, m.p. 250—251°. 3-Chloro-5:6-dibromo- $\psi$ -cumene, m.p. 224°, is obtained from (VII) and Br in AcOH at 70°. 2-Chloro-4:6-diaminomesitylene, m.p. 137—138°, is prepared by reduction ( $\text{SnCl}_2$ ) of the ( $\text{NO}_2$ )<sub>2</sub>-derivative. 3-Bromo-5:6-dinitro- $\psi$ -cumene is reduced ( $\text{SnCl}_2$ , EtOH-HCl) to 5:6-diamino- $\psi$ -cumene, which with (IX) yields 10:11:13-trimethylphenanthrophenazine, m.p. 253°; reduction in AcOH affords 2:4:5:7-tetramethylbenziminazole, m.p. 233°. 6-Bromo- $\psi$ -cumene, b.p. 117°/17 mm., 233° (corr.)/724 mm., is obtained by deamination of 6-bromo-5- $\psi$ -cumidine, m.p. 69° [from (V) (in dil. HCl) and Br in AcOH]. 4-Chloro-5:6-dinitrohemimellitene, m.p. 183°, is similarly reduced to the ( $\text{NH}_2$ )<sub>2</sub>-derivative, m.p. 137—137.5°, which with Ac. and (IX) gives 8-chloro-2:3:5:6:7-pentamethylquinoxaline, m.p. 160.5°, and 13-chloro-10:11:12-trimethylphenanthrophenazine, m.p. 346.5—347°; reduction in AcOH yields 7-chloro-2:4:5:6-tetramethylbenziminazole, m.p. 288.5°. The ( $\text{NO}_2$ )<sub>2</sub>-

derivative, m.p. 196.5°, of 4-bromohemimellitene, b.p. 103—103.5°/12 mm., 229.5°/750 mm., m.p. 1°, on reduction ( $\text{SnCl}_2$ , HCl) and treatment with (IX) gives 10:11:12-trimethylphenanthrophenazine, m.p. 311°. H. B.

**Oxidation in benzene series by gaseous oxygen. V. Oxidation of tertiary hydrocarbons.** H. N. STEPHENS and F. L. RODUTA (J. Amer. Chem. Soc., 1935, 57, 2380—2381).—Slow oxidation ( $\text{O}_2$ ) of  $\text{CHPhMeR}$  ( $\text{R}=\text{Et}$ ,  $\text{Pr}^n$ ,  $\text{Bu}^n$ ) at 119° (bath) gives  $\text{COPhMe}$  but no  $\text{COPhR}$ ;  $\text{CHPh}_2\text{Me}$  and  $\text{CHPh}_3$  similarly afford  $\text{COPh}_2$ . These reactions, unlike that with  $\text{CH}_2\text{Ph}_2$  ( $\rightarrow \text{COPh}_2$ ) (cf. A., 1928, 1233), are not inhibited by  $\text{H}_2\text{O}$ . H. B.

**Reactions between organomercury compounds and nitrosyl compounds.** L. I. SMITH and F. L. TAYLOR (J. Amer. Chem. Soc., 1935, 57, 2460—2463).—Acetoxymercuridurene (I) (in  $\text{CHCl}_3$ ) and  $\text{NOCl}$  (from EtO-NO and AcOH-conc. HCl) give *nitroso-durene* (II), m.p. 160° (decomp.) (rapid heating). *Nitroso-isodurene* (III), m.p. 134°, *pentamethylbenzene*, m.p. 160° (decomp.) (rapid heating), *prehnitene*, m.p. 72°, *mesitylene*, and  $\psi$ -cumene are similarly prepared:  $\text{ArHgX} + \text{NOCl} \rightarrow \text{ArNO} + \text{HgXCl}$ . (I) and (II) are both converted by  $\text{HNO}_3$  (d 1.26) at 70° into *nitrodurene*, m.p. 112—113°; (III) and acetoxymercuridurene (IV) similarly afford *nitroisodurene*, m.p. 38—39°, also prepared from (III) and  $\text{NO}_2$  in  $\text{CHCl}_3$ .  $\text{N}_2\text{O}_3$  distilled into (IV) (in  $\text{CHCl}_3$ ) gives a colourless ppt. of (probably) *nitritomercuroisodurene* contaminated with  $\text{Hg}(\text{NO}_2)_2$ , which subsequently redissolves; a brown ppt. is then formed and the  $\text{CHCl}_3$  contains (III) [similarly obtained from (IV) and  $\text{NO}_2$ ]. The reaction between  $\text{HgPh}_2$  and  $\text{N}_2\text{O}_3$  (Bamberger, A., 1897, i, 288; 1900, i, 145) is considered to give  $\text{PhNO}$  as the primary product;  $\text{PhN}\cdot\text{NO}_3$  is then formed from  $\text{PhNO}$  and  $\text{NO}$ . Diazonium nitrates are formed only when  $\text{N}_2\text{O}_3 + \text{NO}$  (excess) act on Hg compounds. H. B.

**Reaction between chlorodiphenylmethane and ethyl alcohol.** F. G. KNY-JONES and A. M. WARD (J. Amer. Chem. Soc., 1935, 57, 2394—2396). Re-examination of the method previously used (A., 1927, 1061) in greater detail again shows that the reaction,  $\text{CHPh}_2\text{Cl} + \text{EtOH} \rightarrow \text{CHPh}\cdot\text{OEt} + \text{HCl}$ , is irreversible (cf. Norris and Morton, A., 1928, 1000). H. B.

**Polystyrene and the mechanism of polymerisation.** G. S. WHITBY (Trans. Faraday Soc., 1936, 32, 315—323).—Evidence is presented for the view that polymerisation of unsaturated compounds is due to successive additions to the double linking present in the monomeric or the preceding polymeric stage, a H atom going to one side of the double linking and the rest of the addendum to the other. F. L. U.

**Highly polymerised compounds. CXXI. Insoluble polystyrene.** H. STAUDINGER [with HEUER and E. HUSEMANN] (Trans. Faraday Soc., 1936, 32, 323—332).—When styrene (I) is polymerised in presence of *p*-divinylbenzene (II) as product, although highly turgescible, is insol. in the usual solvents. The proportion of (II) needed to render the resulting polystyrene (III) insol. decreases as the chain-length of (III) increases, being, e.g. (11)

(I)=1/50,000 for a highly polymerised product. The insol. product is thus chemically indistinguishable from sol. (III), and the striking difference in physical properties is due to the relatively small no. of "bridges" effected by (II) between the long chains of (III), converting a linear into a three-dimensional polymeride. The results are discussed with reference to sol. and insol. caoutchouc, and to highly polymerised biological materials.

F L U

**Synthesis of diacetylene derivatives.** J. S. SALKIND and F. B. FUNDYLER (Ber., 1936, 69, [B], 128—130).—CPh:CH is converted by heating with a feebly acidified solution of  $\text{NH}_4\text{Cl}$  and excess of  $\text{CuCl}$  into the compound,  $\text{C}_{16}\text{H}_{10}\text{CuCl}$ , immediately decomposed by  $\text{Et}_2\text{O}$  into  $\alpha\delta$ -diphenyl- $\Delta^{\alpha\gamma}$ -butindine (I), m.p. 86—87°. The change appears to be balanced. (I) is hydrogenated (Pt-sponge) to  $\alpha\delta$ -diphenylbutane. The liberated H is involved in the formation of resinous material (?  $\text{C}_{16}\text{H}_{14}$ ). Analogous reactions are given by  $\gamma$ -hydroxy- $\gamma$ -methyl- $\Delta^{\alpha}$ -butinene and hydroxycyclohexylacetylene.

H. W.

**Rearrangements of polyinenes. VII. Formation of allenenes.** J. H. FORD, C. D. THOMPSON, and C. S. MARVEL (J. Amer. Chem. Soc., 1935, 57, 2619—2623).—COPhBu $\gamma$  (I) (2 : 4-dinitrophenylhydrazine, m.p. 194—195°), prepared in 67% yield from  $\text{MgPhBr}$  and  $\text{Bu}^{\gamma}\text{COCl}$  in  $\text{Et}_2\text{O}$  and  $\text{N}_2$ , with  $\text{CBu}^{\gamma}\text{C}^{\gamma}\text{MgBr}$  gives phenyltert.-butyltert.-butylethynylcarbinol (II), b.p. 125—128°/4 mm., converted by  $\text{PBr}_3$  in light petroleum into the carbinyl bromide (III), b.p. 115—117°/1 mm., and by  $\text{AcOH}$ -conc.  $\text{H}_2\text{SO}_4$  into  $\gamma$ -phenyl- $\beta\beta\zeta\zeta$ -tetramethyl- $\Delta^{\gamma}$ -hepten- $\epsilon$ -one, b.p. 96—97°/1 mm., m.p. 30.5° (2 : 4-dinitrophenylhydrazine, m.p. 150—151°). A hydrocarbon could not be prepared from (II) and  $\text{TiCl}_3$  or from (III) and  $\text{Ag}$  or  $\text{Cu}$ . (III) and moist  $\text{Ag}_2\text{O}$  in  $\text{COMe}_2$  give (II). Decomp. of the Grignard reagent (A) from (III) with  $\text{H}_2\text{O}$  affords the allenic hydrocarbon  $\gamma$ -phenyl- $\beta\beta\zeta\zeta$ -tetramethyl- $\Delta^{\gamma\epsilon}$ -heptadiene (IV), b.p. 78—80°/1 mm. [ozonolysis products,  $\text{Bu}^{\gamma}\text{CO}_2\text{H}$  and (I)].  $\text{ClCO}_2\text{Me}$  and (A) similarly give Me  $\gamma$ -phenyl- $\beta\beta\zeta\zeta$ -tetramethyl- $\Delta^{\gamma\epsilon}$ -heptadiene- $\epsilon$ -carboxylate, b.p. 116—120°/2 mm. [free acid, m.p. 160—161°, also formed from (A) and  $\text{CO}_2$ ], which is oxidised ( $\text{O}_3$ ) to the Me ester (2 : 4-dinitrophenylhydrazine, m.p. 205—206°) of trimethylpyruvic acid [2 : 4-dinitrophenylhydrazine, m.p. 169—171° (decomp.)]. (III) does not give a stable Na alkyl when treated with 40% Na-Hg in  $\text{Et}_2\text{O}$  and  $\text{N}_2$ ; decomp. of the product with  $\text{H}_2\text{O}$  affords (IV) and two isomeric hydrocarbons,  $\text{C}_{34}\text{H}_{46}$ , m.p. 148—149° and 115—125°. The same mixture is obtained by reduction (Zn dust,  $\text{EtOH}$ ) of (III) or treatment with Li.  $\alpha$ -Phenyl- $\beta\beta$ -dimethylbutyric acid, m.p. 105°, is prepared from  $\text{CO}_2$  and  $\text{CHPhBu}^{\gamma}\text{MgBr}$ . The acids and esters formed from metallic derivatives of the type  $\text{CR}:\text{C}:\text{CR}'_2\text{M}$  may all be  $\text{CO}_2\text{R}''\text{CR}:\text{C}:\text{CR}'_2$ . H. B.

**Rearrangements of polyinenes. VIII. Formation of diallenes.** E. D. FARLEY and C. S. MARVEL (J. Amer. Chem. Soc., 1936, 58, 29—34).—The hydrocarbon obtained (A., 1932, 505) from diphenyltert.-butylethynylcarbinyl bromide and  $\text{Ag}$  or  $\text{Cu}$ -bronze is now considered to be  $\alpha\alpha\zeta\zeta$ -tetraphenyl- $\gamma\delta$ -ditert.-butyl- $\Delta^{\alpha\beta\gamma\delta}$ -hexatetraene (I),  $(\text{CPh}_2\text{C}^{\gamma}\text{CBu}^{\gamma})_2$ , since oxidation

(dry  $\text{O}_2$  in  $\text{C}_6\text{H}_4\text{Me}_2$  at 140°) gives 52% of  $\text{COPh}_2$ , (apart from products derived from the  $\text{C}_6\text{H}_4\text{Me}_2$ ). (I) could not be oxidised by  $\text{PbO}_2$ ; with  $\text{O}_3$  the products previously reported (*loc. cit.*) and  $\text{BzOH}$  are obtained. The hydrocarbon  $\text{C}_{12}\text{H}_{16}$  [obtained (*ibid.*, 496) from  $\text{CMeEt}_2\text{C}^{\gamma}:\text{C}^{\gamma}:\text{CPh}_2\text{Br}$ ] is also oxidised ( $\text{O}_2$ ) to  $\text{COPh}_2$  (38%); definite products could not be isolated from the hydrocarbon prepared by Moureu *et al.* (A., 1927 355) from  $(\text{CPh}:\text{C}^{\gamma}\text{CPh}_2)_2$ . Reduction of diphenyltert.-butylethynylcarbinol with  $\text{TiCl}_3$  gives (I) and a compound,  $\text{C}_{38}\text{H}_{39}\text{Cl}$ , m.p. 201°. Reduction (Na, amyl alcohol) of (I) affords hydrocarbons,  $\text{C}_{38}\text{H}_{38}$ , m.p. 132 (II), and  $\text{C}_{38}\text{H}_{44}$  [described previously (A., 1932, 505) as  $\text{C}_{19}\text{H}_{22}$ ], m.p. 182°; with red P and 47% HI in  $\text{AcOH}$ , a hydrocarbon,  $\text{C}_{30}\text{H}_{42}$  (III), m.p. 210—211° [which may be the dimeride of 3-phenylindene (Blum-Bergmann, A., 1931, 208)], results. The hydrocarbon,  $\text{C}_{38}\text{H}_{38}$ , m.p. 176°, obtained (*cf. loc. cit.*) from (I) and  $\text{AcOH-HCl}$ , is not oxidised by  $\text{K}_2\text{Cr}_2\text{O}_7$  in  $\text{AcOH}$ , does not give a Na alkyl with 40% Na-Hg, but is reduced (P, HI,  $\text{AcOH}$ ) to (III). (I) and 40% Na-Hg in  $\text{Et}_2\text{O}$  and  $\text{N}_2$  afford a product (A) containing  $\text{CNaPh}_2\text{C}^{\gamma}:\text{C}^{\gamma}\text{CBu}^{\gamma}$  [since treatment with  $\text{CO}_2$  gives a little  $\text{CBu}^{\gamma}:\text{C}^{\gamma}\text{CPh}_2\text{CO}_2\text{H}$  (A., 1932, 50)] and an additive compound  $\text{C}_{38}\text{H}_{38}\text{Na}_2$  [since the action of  $\text{H}_2\text{O}$  affords a hydrocarbon,  $\text{C}_{38}\text{H}_{40}$  (IV), m.p. 163° (*loc. cit.*), whilst  $\text{ClCO}_2\text{Me}$  gives an ester,  $\text{C}_{38}\text{H}_{38}(\text{CO}_2\text{Me})_2$ , m.p. 173°, which when (partly) hydrolysed ( $\text{MeOH-KOH}$ ) and then heated passes into an ester,  $\text{C}_{38}\text{H}_{39}\text{CO}_2\text{Me}$ , m.p. 162°]. Oxidation of (IV) with  $\text{KMnO}_4$  in  $\text{COMe}$  gives a neutral compound,  $\text{C}_{38}\text{H}_{39}\text{O}_2$ , m.p. 217—218°; with  $\text{K}_2\text{Cr}_2\text{O}_7$  in  $\text{AcOH}$ , a neutral compound,  $\text{C}_{38}\text{H}_{28}\text{O}_3$  (V), m.p. 169°, results. Reduction (Na, amyl alcohol) of (IV) affords a hydrocarbon,  $\text{C}_{38}\text{H}_{42}$  (VI), m.p. 197°, and a mixture (B) of (VI) and a more fusible isomeride; the hydrocarbon,  $\text{C}_{38}\text{H}_{42}$ , m.p. 181—182°, previously described (A., 1932, 505), is identical with (B). (VI) is also obtained by successive treatment of (IV) with 40% Na-Hg and  $\text{H}_2\text{O}$ . The hydrocarbon,  $\text{C}_{38}\text{H}_{38}$ , m.p. 179—180° (*loc. cit.*), prepared from (A) and  $\text{C}_2\text{Me}_4\text{Br}_2$ , is oxidised ( $\text{K}_2\text{Cr}_2\text{O}_7$ ,  $\text{AcOH}$ ) to (V), is reduced (Na, amyl alcohol) to (VI) and an isomeride, m.p. 155—156°, and is converted by successive treatment with 40% Na-Hg and  $\text{H}_2\text{O}$  into (IV).

The Na alkyl from  $\alpha\alpha$ -diphenyl- $\delta\delta$ -dimethyl- $\Delta^{\alpha\beta}$ -pentadiene (A., 1932, 50) and 40% Na-Hg with  $\text{C}_2\text{Me}_4\text{Br}_2$  gives a hydrocarbon,  $\text{C}_{38}\text{H}_{40}$ , m.p. 143—144°; the dimeride (VII) (*loc. cit.*) similarly regenerates (VII), but decomp. with  $\text{H}_2\text{O}$  affords a hydrocarbon,  $\text{C}_{38}\text{H}_{44}$ , m.p. 133° [probably formed also by reduction (Na, amyl alcohol) of (VII)], which differs from (II). Reduction (red P, 47% HI,  $\text{AcOH}$ ) of (VII) affords a hydrocarbon,  $\text{C}_{38}\text{H}_{42}$ , m.p. 134—135°, whilst oxidation ( $\text{K}_2\text{Cr}_2\text{O}_7$ ,  $\text{AcOH}$ ) gives a little of a neutral compound,  $\text{C}_{26}\text{H}_{26}\text{O}_2$ , m.p. 227°, but no  $\text{COPh}_2$ . H. B.

**Mol. compounds of polycyclic hydrocarbons and their quinones with polynitro-compounds and with metallic salts.** K. BRASS and K. FANTA (Ber., 1936, 69, [B], 1—11).—Examination of many compounds fails to confirm Bruni's view (A., 1906, i, 491) that the power of adding  $\text{NO}_2$ -compounds depends essentially on the  $\text{C}_6\text{H}_6$  nucleus and that the no. of added mols. is in the limit equal to the no. of independent  $\text{C}_6\text{H}_6$  nuclei present in the hydrocarbon

and that polynuclear condensed mols. add only 1 mol. of  $\text{NO}_2$ -compounds. Perylene does not add dipicric acid (I), but with styphnic acid (II) gives a compound (1:1), m.p.  $211^\circ$ . 2:3:10:11-Dibenzperylene affords the compounds,  $\text{C}_{28}\text{H}_{16}$ ,  $2\text{C}_6\text{H}_5\text{O}_7\text{N}_3$ , m.p.  $240^\circ$  (decomp.),  $\text{C}_{28}\text{H}_{16}$ ,  $2\text{C}_6\text{H}_5\text{O}_8\text{N}_3$ , decomp.  $236^\circ$ ,  $\text{C}_{28}\text{H}_{16}$ ,  $\text{SbCl}_5$ , and  $\text{C}_{28}\text{H}_{16}$ ,  $\text{SnCl}_4$ . 1:12-Benzperylene does not add (I), but affords the substances,  $\text{C}_{22}\text{H}_{12}$ ,  $\text{C}_6\text{H}_5\text{O}_7\text{N}_3$ , m.p.  $267^\circ$ ,  $\text{C}_{22}\text{H}_{12}$ ,  $\text{C}_6\text{H}_5\text{O}_8\text{N}_3$ , m.p.  $234^\circ$ ,  $2\text{C}_{22}\text{H}_{12}$ ,  $\text{SbCl}_5$ , and  $\text{C}_{22}\text{H}_{12}$ ,  $2\text{SnCl}_4$ . 2:3-Benzanthracene does not unite with picric acid (III), dibromopicric acid (IV), (I), or (II), but gives the substances,  $2\text{C}_{18}\text{H}_{12}$ ,  $\text{SbCl}_5$  and  $\text{C}_{18}\text{H}_{12}$ ,  $2\text{SnCl}_4$ . Addition of (I), (II), (III), or (IV) to 2:3-benzanthraquinone is not observed, but the compounds,  $\text{C}_{18}\text{H}_{10}\text{O}_2$ ,  $2\text{SbCl}_5$  and  $\text{C}_{18}\text{H}_{10}\text{O}_2$ ,  $2\text{SnCl}_4$ , have been isolated. 1:2-Benzanthracene gives the compounds,  $\text{C}_{18}\text{H}_{12}$ ,  $\text{C}_6\text{H}_5\text{O}_7\text{N}_3$ , m.p.  $141.5\text{--}142.5^\circ$ ,  $\text{C}_{18}\text{H}_{12}$ ,  $\text{C}_6\text{H}_5\text{O}_8\text{N}_3$ , m.p.  $153^\circ$ , and  $2\text{C}_{18}\text{H}_{12}$ ,  $\text{SbCl}_5$ . 1:2-Benzanthraquinone does not add (I), (II), (III), or (IV), but affords the substances,  $\text{C}_{18}\text{H}_{10}\text{O}_2$ ,  $\text{SbCl}_5$  and  $2\text{C}_{18}\text{H}_{10}\text{O}_2$ ,  $\text{SnCl}_4$ ,  $\text{CHCl}_3$ . (III) is not added by 3-isopropyl-, m.p.  $154\text{--}155^\circ$ , 7-isopropyl-, m.p.  $114^\circ$ , 4-methyl-, m.p.  $168\text{--}169^\circ$ , 5-methyl-, m.p.  $173.5\text{--}174.5^\circ$ , or 6-methyl-, m.p.  $174^\circ$ , 1:2-benzanthraquinone. Additive compounds of 9:9'-dianthryl with (II), (III), or (IV) could not be isolated;  $\text{SnCl}_4$  causes halochromism, whilst  $\text{SbCl}_5$  affords the substance,  $\text{C}_{28}\text{H}_{18}$ ,  $\text{SbCl}_5$ . 9:9'-Dianthranthylquinone does not add (I), (II), (III), or (IV), but gives the compounds,  $\text{C}_{28}\text{H}_{16}\text{O}_2$ ,  $2\text{SbCl}_5$  and  $\text{C}_{28}\text{H}_{16}\text{O}_2$ ,  $2\text{SnCl}_4$ . H. W.

**Action of oleum on decahydronaphthalene.** E. I. PROKOPETZ (J. Appl. Chem. Russ., 1935, 8, 1214—1215).—When *cis-trans*-decahydronaphthalene is shaken with 20% oleum, only the *cis*-isomeride is oxidised, leaving the pure *trans*-isomeride. R. T.

**Rubrene problem.** A. SCHONBERG (J. Amer. Chem. Soc., 1936, 58, 182; cf. A., 1934, 643).—A question of priority (cf. Eck and Marvel, A., 1935, 1492). H. B.

**Attempts to obtain rubenes soluble in water. Hexabromotetraphenylrubene; its transformation into rubenepolycarboxylic acids.** C. DUFRAISSE and L. VELLUZ (Bull. Soc. chim., 1936, [v], 3, 254—265).— $p\text{-C}_6\text{H}_4\text{Br}\cdot\text{C}\cdot\text{MgBr}$  and  $\text{CO}(\text{C}_6\text{H}_4\text{Br}\cdot p)_2$  give  $\alpha\gamma\gamma$ -tri-*p*-bromophenylpropinen- $\gamma$ -ol, m.p.  $141\text{--}142^\circ$  (*Me* ether, m.p.  $101\text{--}102^\circ$ ); this with  $\text{H}_2\text{SO}_4\text{--Bu}_2\text{O}$  gives *p*- $\text{C}_6\text{H}_4\text{Br}$  *pp'*-dibromohydrindenylmethyl ketone, m.p. ( $+ \text{C}_6\text{H}_6$ )  $114\text{--}115^\circ$  and (anhyd.)  $135\text{--}136^\circ$ , which with  $\text{PCl}_3$  in ligroin affords the chloride, m.p.  $130\text{--}131^\circ$  (dimeride, m.p.  $273\text{--}275^\circ$ ), converted in quinoline at  $100^\circ/15\text{--}16$  mm. into 5:5'- (or 5:6'-)dibromo-1:3:1':3'-tetra-*p*-bromophenylrubene (bisindenyl formulation), m.p.  $401\text{--}402^\circ$  (cryst. peroxide loses 75% of its O at  $150\text{--}200^\circ$ ). Four Br readily and the last two very slowly react with Mg;  $\text{CO}_2$  then leads to an amorphous acid ( $\text{H}_2\text{O}$ -sol. Na salt), which forms a dissociable peroxide. M.p. are taken on a block. R. S. C.

**Chemical interrelationships in the cholane group.** H. JENSEN (J. Chem. Educ., 1935, 12, 559—564).—A review. L. S. T.

**Synthesis of compounds related to sterols, bile acids, and oestrus-producing hormones.** VIII. C. L. HEWETT. IX. A. COHEN, J. W. COOK, and C. L. HEWETT. X. Ruzicka's hydrocarbon " $\text{C}_{21}\text{H}_{36}$ " from cholic acid. W. E. BACHMANN, J. W. COOK, C. L. HEWETT, and J. IBALL (J.C.S., 1936, 50—52, 52—53, 54—61).—VIII. Dihydroresorcinol (I) (1 mol.) and  $\text{CH}_2\text{PhCl}$  (1 mol.) in  $\text{EtOH-NaOEt}$  (1 mol.) give some benzylcyclohexane-2:6-dione, m.p.  $184\text{--}185^\circ$ , converted by conc.  $\text{H}_2\text{SO}_4$  at  $-15^\circ$  into a  $\text{SO}_3\text{H}$  derivative ( $+ \text{H}_2\text{O}$ ), m.p.  $193\text{--}194^\circ$ .  $\beta$ -*m*-Methoxyphenylethyl bromide (II), b.p.  $138^\circ/12$  mm., and (I) similarly afford (mainly) the  $\beta$ -*m*-methoxyphenylethyl ether, b.p.  $205\text{--}207^\circ/0.5$  mm., of (I) and a little  $\beta$ -*m*-methoxyphenylethylcyclohexane-2:6-dione, m.p.  $149\text{--}150^\circ$  (cf. Robinson and Schittler, A., 1935, 1498), which is best converted into 1-keto-7-methoxy-1:2:3:4:9:10-hexahydrophenanthrene (*loc. cit.*) by 80%  $\text{H}_2\text{SO}_4$  at  $100^\circ$  (bath).  $\alpha\text{-C}_{10}\text{H}_7\cdot\text{CH}_2\cdot\text{CH}_2\text{Br}$  and (I) give 3-keto- $\Delta^1$ -cyclohexenyl  $\beta$ -1-naphthylethyl ether, m.p.  $138\text{--}139^\circ$ , hydrolysed (aq.  $\text{EtOH-KOH}$  or  $\text{NH}_2\text{OH}\cdot\text{HCl}$  in  $\text{C}_5\text{H}_5\text{N}$  at  $100^\circ$ ) to  $\alpha\text{-C}_{10}\text{H}_7\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{OH}$ . Hydrolysis (dil.  $\text{HCl}$ ) of the product from *m*- $\text{OMe}\cdot\text{C}_6\text{H}_4\cdot\text{MgBr}$  and  $(\text{CH}_2)_2\text{O}$  at  $100^\circ$  ( $\text{Et}_2\text{O}$  removed first) gives  $\beta$ -*m*-methoxyphenylethyl alcohol, b.p.  $150\text{--}155^\circ/18$  mm. (3:5-dinitrobenzoate, m.p.  $106.5\text{--}107.5^\circ$ ), converted by  $\text{PBr}_3$  in  $\text{CCl}_4$  into (II). Modified preps. of *m*- $\text{C}_6\text{H}_4\text{Br}\cdot\text{OH}$  (from *m*- $\text{C}_6\text{H}_4\text{Br}\cdot\text{NH}_2$  and *m*- $\text{C}_6\text{H}_4\text{Br}\cdot\text{OMe}$  are given. 2-Acetyl-1-methyl- $\Delta^1$ -cyclopentene (from 1-methyl- $\Delta^1$ -cyclopentene and  $\text{AcCl}$  in  $\text{CS}_2\text{--SnCl}_4$ ) and  $\text{CH}_2\text{Ph}\cdot\text{CH}_2\cdot\text{CH}(\text{CO}_2\text{Et})_2$  in  $\text{EtOH-NaOEt}$  afford a little of (probably) the acid (III), m.p.  $242^\circ$ .

IX.  $\beta$ -6-Methoxy-1-naphthylethyl bromide and  $\text{CHK}(\text{CO}_2\text{Et})_2$  in  $\text{PhMe}$  at  $120\text{--}130^\circ$  give the *Et* ester, b.p.  $200\text{--}205^\circ/0.3$  mm., of  $\beta$ -6-methoxy-1-naphthylethylmalonic acid, m.p.  $160^\circ$  (decomp.), decarboxylated at  $190^\circ$  to  $\gamma$ -6-methoxy-1-naphthylbutyric acid, m.p.  $150\text{--}151^\circ$  [*Et* ester (I), b.p.  $169^\circ/0.2$  mm.]. 1-Keto-7-methoxy-1:2:3:4-tetrahydrophenanthrene (Butenandt and Schramm, this vol., 76) and a little of the 7-OH-ketone are formed from (I) and 80%  $\text{H}_2\text{SO}_4$  at  $100^\circ$ . The product from (I) and  $\text{Et}_2\text{C}_2\text{O}_4$  in  $\text{Et}_2\text{O}+\text{KOEt}$  is converted by warm 80%  $\text{H}_2\text{SO}_4$  into 7-methoxy-3:4-dihydrophenanthrene-1:2-dicarboxylic anhydride, m.p.  $217.5\text{--}218.5^\circ$ , which is demethylated [ $\text{HBr}$  (d 1.48) in  $\text{AcOH}$ ] to 7-hydroxy-3:4-dihydrophenanthrene-1:2-dicarboxylic anhydride, m.p.  $275\text{--}278^\circ$  (previous sintering), and dehydrogenated ( $\text{Pt-black}$  at  $300^\circ$ ) to 7-methoxyphenanthrene-1:2-dicarboxylic anhydride, m.p.  $260\text{--}261^\circ$  (corr.) (cf. this vol., 71).

X (cf. A., 1935, 1359). The carbinol from 2-methylhydrindone and  $\alpha\text{-C}_{10}\text{H}_7\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{MgBr}$  (I) is dehydrated ( $\text{KHSO}_4$  at  $160^\circ$ ) (general procedure) to 3- $\beta$ -1'-naphthylethyl-2-methylindene, m.p.  $99\text{--}99.5^\circ$  (dipicrate, m.p.  $161\text{--}161.5^\circ$ ), which is cyclised by  $\text{AlCl}_3$  in  $\text{CS}_2$  at  $0^\circ$  (general method) to 10-methyl-3:4:10:11-tetrahydro-2':1'-naphtha-1:2-fluorene (II), m.p.  $111\text{--}112^\circ$ , dehydrogenated (Se at  $310^\circ$ ; general method) to 2':1'-naphtha-1:2-fluorene, m.p.  $328^\circ$  (*ibid.*, 74). *p*-Methylbenzylmethylmalonic acid, m.p.  $178\text{--}180^\circ$

(decomp.) [the *Et* ester, b.p. 203—210°/26 mm., is prepared from  $p\text{-C}_6\text{H}_4\text{Me}\cdot\text{CH}_2\text{Br}$  and  $\text{CNaMe}(\text{CO}_2\text{Et})_2$  in  $\text{EtOH}$ ], is decarboxylated at 180° to  $\beta\text{-}p\text{-tolyl-}\alpha\text{-methylpropionic acid}$ , b.p. 181—182°/23 mm., m.p. 30—31·5°, the chloride, b.p. 139—141°/21 mm., of which with  $\text{AlCl}_3$  in ligroin gives 2:6-dimethylhydrindone, b.p. 145—

148°/21 mm. [*phenylhydrazone*, m.p. 173—175° (decomp.)]. This and (I) lead to  $\beta\text{-}1'\text{-naphthylethyl-2:5-dimethylindene}$ , m.p. 81—81·5° (*dipicrate*, m.p. 144—144·5°), converted into 6:10-dimethyl-3:4:10:11-tetrahydro-2':1'-naphtha-1:2-fluorene, m.p. 106·5—107° (*semipicrate*, m.p. 133·5—134°), and thence into 6-methyl-2':1'-naphtha-1:2-fluorene, m.p. 330° (varies with rate of heating), which is oxidised ( $\text{K}_2\text{Cr}_2\text{O}_7$ ,  $\text{AcOH}$ ) to the -1:2-fluorenone, m.p. 225—226°. *m*-Methylbenzylmethylmalonic acid, m.p. 152—153° (decomp.), is similarly converted through  $\beta\text{-}m\text{-tolyl-}\alpha\text{-methylpropionic acid}$ , b.p. 178—179°/20 mm. (chloride, b.p. 137—138°/21 mm.), into 2:5-dimethylhydrindone, b.p. 142—144°/21 mm. [2:4-dinitrophenylhydrazone, m.p. 225—226° (decomp.)], which with (I) gives  $\beta\text{-}3\text{-}1'\text{-naphthylethyl-2:6-dimethylindene}$ , b.p. 184—186°/0·05 mm., cyclised to 7:10-dimethyl-3:4:10:11-tetrahydro-2':1'-naphtha-1:2-fluorene, m.p. 134·5—135° [accompanied by some  $\alpha\delta\text{-di-1-naphthylbutane}$ , m.p. 101° (*dipicrate*, m.p. 174—175°), which is undoubtedly present as an impurity in the indene; it is now prepared from  $\alpha\text{-C}_{10}\text{H}_7\cdot\text{CH}_2\cdot\text{CH}_2\text{Br}$  and  $\text{Mg}$ ]. 7-Methyl-2':1'-naphtha-1:2-fluorene, m.p. 334—336°, is oxidised to the -1:2-fluorenone, m.p. 175—176·5°. *o*-Methylbenzylmethylmalonic acid, m.p. 125—123°, similarly yields  $\beta\text{-o-tolyl-}\alpha\text{-methylpropionic acid}$ , b.p. 179—180°/20 mm. (chloride, b.p. 137—138°/21 mm.), and thence 2:4-dimethylhydrindone, b.p. 147—149°/20 mm. [*semicarbazone*, m.p. 224—225° (decomp.)]. This and (I) lead to  $\beta\text{-}3\text{-}1'\text{-naphthylethyl-2:7-dimethylindene}$ , m.p. 96°, resolidifying with m.p. 113·5—114°, cyclised to 8:10-dimethyl-3:4:10:11-tetrahydro-2':1'-naphtha-1:2-fluorene, m.p. 121—122° (*semipicrate*, m.p. 130·5—131·5°), dehydrogenated to 8-methyl-2':1'-naphtha-1:2-fluorene (III), m.p. 281—281·5° (corr.) (fluorenone, m.p. 237—238°). Hydrolysis (aq.  $\text{MeOH-KOH}$ ) of the product from  $\text{CNaMe}(\text{CO}_2\text{Et})_2$  and 4-bromo-3-bromomethyltoluene, b.p. 148—152° (from  $m\text{-C}_6\text{H}_4\text{Me}\cdot\text{CH}_2\text{Br}$ ,  $\text{Br}$ , and  $\text{Fe}$  powder at 0°), or a mixture of 4-bromo-2- and -3-chloromethyltoluenes (Fieser and Seligman, A., 1935, 853), gives 2-bromo-5-methylbenzylmethylmalonic acid, m.p. 179—180° (decomp.), converted through  $\alpha\text{-2-bromo-5-methylbenzylpropionic acid}$ , m.p. 84—85° (chloride, b.p. 173—174°/20 mm.), into 4-bromo-2:7-dimethylhydrindone, b.p. 115—117°/0·15 mm. This and (I) lead to 7-bromo-3- $\beta\text{-}1'\text{-naphthylethyl-2:4-dimethylindene}$ , m.p. 84—85° (*dipicrate*, m.p. 142·5—143·5°), which is cyclised to 8-bromo-5:10-dimethyl-3:4:10:11-tetrahydro-2':1'-naphtha-1:2-fluorene, m.p. 137·5—138·5°, dehydrogenated to 5-methyl-2':1'-naphtha-1:2-fluorene (IV), m.p. 275—276° (corr.) (fluorenone (V), m.p. 209—210°). Hydrolysis (aq.  $\text{NH}_4\text{Cl}$ ) of the product obtained from  $\alpha\text{-C}_{10}\text{H}_7\cdot\text{MgBr}$  and propylene oxide at 100° ( $\text{Et}_2\text{O}$  first removed)

gives  $\alpha\text{-1-naphthylisopropyl alcohol}$ , b.p. 148—155°/25 mm. [3:5-dinitrobenzoate, m.p. 171—172°; chloride (VI), b.p. 131°/6 mm.]. Cyclisation of a fraction, b.p. 195—215°/0·8 mm., obtained from 2-methylhydrindone, the Grignard reagent from (VI), and  $\text{MgEtBr}$  (1 mol.) gives  $\alpha\delta\text{-di-1-naphthyl-}\beta\text{-}\gamma\text{-dimethylbutane}$ , m.p. 131—132° (removed as picrate), and resinous material, dehydrogenated with  $\text{Se}$  to a little 4-methyl-2':1'-naphtha-1:2-fluorene, m.p. 202—203° (corresponding fluorenone, m.p. 214—215°). All the methylnaphthafluorenones give intense purple colours, gradually changing to magenta, with conc.  $\text{H}_2\text{SO}_4$ .

Comparison (m.p.; colour with  $\text{H}_2\text{SO}_4$ ) of (V) and the ketone obtained by oxidation of the hydrocarbon,  $\text{C}_{21}\text{H}_{16}$  (VII), of Ruzicka *et al.* (A., 1933, 278; 1934, 398) shows their identity. Powder photographs of (IV) and (VII), which are first fused under identical conditions, are very similar; the slight difference is ascribed to impurity in (VII). Crystallographic data for (III) and (IV) are given. The production of (VII) [*i.e.*, (IV)] from cholic acid is due to simple cyclisation of the side-chain during dehydrogenation. H. B.

**Alkali fusion. I. Fusion of potassium sulphanilate with alkali.** N. N. VOROSCHCOV and M. M. SCHEMJAKIN (Ber., 1936, 69, [B], 148—152).— $p\text{-NH}_2\cdot\text{C}_6\text{H}_4\cdot\text{SO}_3\text{K}$  when heated with a large excess of  $\text{KOH}$  at 350—355° in  $\text{N}_2$  gives  $\text{NH}_3$  (76·7%); the normal exchange of  $\cdot\text{SO}_3\text{K}$  for  $\cdot\text{OK}$  occurs to only a slight extent since only 1·5% of  $\text{SO}_3$  is observed. At higher temp. (> 400°) the yield of  $\text{SO}_3$  increases but the product becomes carbonised. Although  $p\text{-NH}_2\cdot\text{C}_6\text{H}_4\cdot\text{SO}_3\text{K}$  enters almost quantitatively into reaction the product does not contain  $\text{NH}_2\text{Ph}$ ,  $\text{PhOH}$ , or  $\text{NH}_2\cdot\text{C}_6\text{H}_4\cdot\text{OH}$ .  $p\text{-OH}\cdot\text{C}_6\text{H}_4\cdot\text{SO}_3\text{H}$  is formed in 77·53% yield. H. W.

**Action of sodium on aromatic nitro- and nitroso-compounds.** V. O. LUKASHEVITSCH (Annalen, 1936, 521, 198—214).—The Na compounds of aryl  $\text{NO}_2$ - and  $\text{NO}$ -derivatives (Schmidt, A., 1900, i, 20) are best prepared by the action of 0·5% Na-Hg on the  $\text{NO}_2$ - or  $\text{NO}$ -compound in dry  $\text{Et}_2\text{O}$ ,  $\text{C}_6\text{H}_6$ , or  $\text{PhMe}$  ( $\text{N}_2$  atm.). The structures  $\text{R}\cdot\text{N}(\text{ONa})_2$  (I), and  $\text{R}\cdot\text{NNa}\cdot\text{ONa}$  (II), respectively, are suggested. The reactions (I) +  $\text{R}'\text{NO}_2 \rightleftharpoons \text{R}'\text{N}(\text{ONa})_2 + \text{RNO}_2$  (A), and (II) +  $\text{R}'\text{NO} \rightleftharpoons \text{R}'\text{NONa}_2 + \text{RNO}$  (B), are reversible, but the reaction (I) +  $\text{R}'\text{NO} \rightarrow \text{R}'\text{NONa}_2 + \text{RNO}_2$  (C) proceeds only from left to right. These relationships are established by investigation of the products of interaction of (I) or (II) (or mixtures in accordance with equations A, B, or C) with  $\text{BzCl}$ , dil.  $\text{H}_2\text{SO}_4$ , or  $\text{H}_2\text{O}$ , numerous examples being given. Thus with  $\text{BzCl}$  (I) reacts: (I) +  $2\text{BzCl} \rightarrow \text{RN}(\text{OBz})_2 \rightarrow \text{Bz}_2\text{O} + \text{RNO}$ , which then reacts as C to give (II), which with  $\text{BzCl}$  affords  $\text{RNBz}\cdot\text{OBz}$  (III). The isolation of  $\text{Bz}_2\text{O}$  and various dibenzoylarylhydroxylamines in yields closely corresponding with these equations is described. With  $\text{H}_2\text{O}$  or dil.  $\text{H}_2\text{SO}_4$  (I) gives the corresponding  $\text{NHR}\cdot\text{OH}$  (isolated cryst., and determined in the mother-liquor by reduction of 2—3%  $\text{AgNO}_3$ ), and with  $\text{PhNO}_2$ , *o*-, *m*-, and *p*- $\text{C}_6\text{H}_4\text{MeNO}_2$  the yields of  $\text{NHR}\cdot\text{OH}$  are, respectively, 79·1, 90·9, 85·3, and 83·3%. By the action of  $\text{BzCl}\cdot\text{C}_5\text{H}_5\text{N}$  on the appropriate  $\text{NHR}\cdot\text{OH}$  in dry  $\text{Et}_2\text{O}$  ( $\text{N}_2$ ) are obtained  $\text{NO}$ -

*dibenzoyl-phenyl*-, m.p. 118—118.8°, -o-, m.p. 137—138°, -m-, m.p. 114.5—115.5°, and -*p*-tolyl-, m.p. 127—127.8°, and -*p*-chlorophenyl-, m.p. 86—87°, -*hydroxylamine* [all identical with the derivatives (III)], from which, by hydrolysis with cold NaOH-MeOH, are obtained *N*-benzoyl-phenyl-, m.p. 121—122°, -*p*-tolyl-, m.p. 109—110°, and -o- (? -*p*-)chlorophenyl-, m.p. 157° (decomp.), -*hydroxylamine*. J. W. B.

**Manufacture of derivatives of *N*-butylaniline.**—See B., 1936, 91.

**Synthesis of aromatic nitro-compounds with the azide group in the side-chain.** J. JUSCHT-SCHENKO (Mem. Inst. Ukrain. Acad. Sci., 1935, 2, 195—205).—o-, b.p. 121—122°/2 mm., and *p*-Nitrobenzyl azide, b.p. 144—148°/2 mm., and 2 : 4-dinitrobenzyl azide, m.p. 46—47°, have been prepared from NaN<sub>3</sub> or AgN<sub>3</sub> and the appropriate chlorides or iodides in EtOH or Et<sub>2</sub>O (8—10 hr. at the b.p.). The azides yield the corresponding aldehydes, NH<sub>3</sub>, and N<sub>2</sub> when treated with hot dil. H<sub>2</sub>SO<sub>4</sub>. R. T.

**Interaction of amines and ammonia with di(diphenylene)ethylene.** L. A. PINCK and G. E. HILBERT (J. Amer. Chem. Soc., 1935, 57, 2398—2402).—Di(diphenylene)ethylene (I) and NH<sub>2</sub>Et at 65° for 2 days give 9-ethylamino-9 : 9'-difluorenyl (II), m.p. 165° [hydrochloride, m.p. 210—215° (decomp.)]; picrate, m.p. 228° (decomp.); NO-derivative, m.p. 217°, and small amounts of fluorene (III) and 9 : 9'-difluorenyl (IV). (II) heated with EtOH for 10 days affords (III), 9-ethyliminofluorene (V) [picrate, m.p. 206° (decomp.)], and fluorenone (VI) [formed by hydrolysis of (V)]; in NH<sub>2</sub>Et at 85° (sealed tube), (III) and (IV) are produced. (I) and NH<sub>2</sub>Me at room temp. similarly afford 9-methylamino-9 : 9'-difluorenyl, m.p. 151° (Ac, m.p. 232°, and NO-, m.p. 203°, derivatives). 9-Dimethylamino-9 : 9'-difluorenyl has m.p. 215° (decomp.). (I) and CH<sub>3</sub>Ph·NH<sub>2</sub> at 100°/6 days give 9-benzylamino-9 : 9'-difluorenyl (VII), m.p. 168° (hydrochloride, m.p. 215—218°; NO-derivative, m.p. 217—218°), (III), (IV), a base, C<sub>21</sub>H<sub>22</sub>N<sub>2</sub>, m.p. 90° (dihydrochloride, m.p. 212°), and a hydrocarbon, m.p. 318°; at room temp./6 months, (VII) appears to be the sole product. (VII) heated in EtOH at 100° (sealed tube) gives (III), (VI), PhCHO, and a little of an unidentified product, m.p. 202°. (I) and liquid NH<sub>3</sub> at 65° for 3 weeks afford (III), 9-iminofluorene, m.p. 123° [hydrochloride, m.p. 303° (decomp.)] [which with NH<sub>2</sub>Et at 55° gives (V)], and a compound, m.p. 300°. The rate of addition of amines to (I) is NH<sub>2</sub>Me > NH<sub>2</sub>Et > NHMe<sub>2</sub> > CH<sub>3</sub>Ph·NH<sub>2</sub> > NH<sub>3</sub> > NHEt<sub>2</sub>, NH<sub>2</sub>Ph. All m.p. are corr. H. B.

**Attempted formation of rings attached to the *p*-positions of the phenyl groups in 2 : 2'-diphenyldiphenyl.** S. SAKO (Bull. Chem. Soc. Japan, 1935, 10, 585—592).—4'-Nitro-2-aminodiphenyl hydrochloride (improved prep.) is converted by diazotisation-KI into 2-iodo-4'-nitro-, m.p. 100—101.5°, reduced (SnCl<sub>2</sub>-HCl-EtOH) to 2-iodo-4'-amino-diphenyl (hydrochloride; Ac derivative, m.p. 162—163°), converted by Cu powder (1.4 times the theoretical quantity gives highest yield of 53%) at 220—225° into 2 : 2'-bis-(*p*-nitrophenyl)diphenyl (I), m.p. 290°, and (?) 4-o-iodophenyl-4'-(2''''-*p*-nitrophenyl-2''-di-

phenyl)azobenzene (annexed), m.p. 312—313° (dimorphous). Reduction of (I) with SnCl<sub>2</sub>-HCl-AcOH

at 60—70°, or with Na<sub>2</sub>S-EtOH, affords 2 : 2'-bis-*p*-aminophenyl- (II), b.p. 290°/5 mm., m.p. 163—164°, converted (Sandmeyer) into 2 : 2'-bis-*p*-iodo- (III), m.p. 205—206°, and 2 : 2'-bis-*p*-bromophenyl- (IV), m.p. 170—171°, -diphenyl. With Na in boiling Et<sub>2</sub>O (III) and (IV) give only 2 : 2'-diphenyldiphenyl, and various other attempts to prepare large rings from (I) and (II) by ring-closure between the substituent groups were unsuccessful. J. W. B.

**Synthesis of 2 : 2'-diphenylbenzidine.** S. SAKO (Bull. Chem. Soc. Japan, 1935, 10, 593—594).—Diazotised 5-nitro-2-aminodiphenyl with KI affords 2-iodo-*o*-nitrodiphenyl, b.p. 191—192°/4 mm., m.p. 114°, converted by heating with Cu powder at 215—225° into 4 : 4'-dinitro-2 : 2'-diphenyldiphenyl, b.p. 290°/4 mm., m.p. 218—219°, reduced (SnCl<sub>2</sub>-HCl-AcOH) to 2 : 2'-diphenylbenzidine, m.p. 151—152°. J. W. B.

***o*-Quinonephenylhydrazones.** A. BURAWOY (Annalen, 1936, 521, 298—302).—A criticism of the views of Kuhn *et al.* (A., 1935, 613). The author's earlier views regarding the *o*-quinonephenylhydrazone structure of *o*-hydroxyazobenzenes (A., 1934, 401 and references there cited) are maintained. J. W. B.

**Diazo-compounds. VII. Diazo-resins. VIII. Coupling and oxidising power of normal diazotates during their decomposition. IX. Reversion of isodiazotates into normal diazotates; its application in dyeing and in negative diazo-type [printing]. X. Rapid preparation of solutions of alkali diazotates from diazonium salts. XI. Constitution of diazonium salts and of alkali diazotates.** G. ODDO and R. INDOVINA (Gazzetta, 1935, 65, 1037—1054, 1054—1067, 1099—1104, 1104—1105, 1105—1127; cf. this vol., 199).—VII. The yield of the resins from 32 diazotised amines decomposing in presence of 0.4, 0.8, and 1.6% NaOH (cf. A., 1899, i, 543) varies with the nature of the amine (least from *o*-NO<sub>2</sub>·C<sub>6</sub>H<sub>4</sub>·NH<sub>2</sub>; most from halogenated amines, and anisidine), and irregularly with the alkalinity. The resins contain N in varying amount and may be separated into fractions richer and poorer in N by pptn. by light petroleum from C<sub>6</sub>H<sub>6</sub> solution. *o*-C<sub>6</sub>H<sub>4</sub>Me·NH<sub>2</sub> yields indazole and its *o*-tolueneazo-derivative; *p*-xylylene gives 6-methylindazole and its *p*-xylyleneazo-derivative; *ψ*-cumidine, dimethylindazole and its *ψ*-cumeneazo-derivative; mesidine forms similar products. The resins all contain hydroxyazo- or bisazo-compounds, and are sulphated by oleum. Some contain diazoamino-compounds. The results are tabulated and discussed; formation of resins is considered due essentially to coupling of diazo-compounds with decomp. products, e.g. phenols, amines, or indazole; autoxidation plays an insignificant part.

VIII. As diazotised amines decompose in presence of NaOH they lose their power to couple with  $\beta$ - $C_{10}H_7OH$ , and take progressively longer to give a (delayed) blue coloration with starch-KI paper. Both reactions are negative when  $N_2$  has ceased to be evolved; their progressive decrease with decomp. of 32 diazotised amines is tabulated, and the oxidising action discussed.

IX. *iso*Diazotates (I) are reconverted into normal diazotates (II) by the action of heat or light (sun, ultra-violet, or electric). Azo-pigments are formed when (I) are mixed with 1%  $\beta$ - $C_{10}H_7OH$  in 1% NaOH and exposed to light. The reaction is given by (I) from  $NH_2Ph$ , *o*-4-xylydine, and *o*-, *m*-, and *p*- $C_6H_4XNH_2$  ( $X=Cl, Br, \text{ or } I$ ), but not by those from *o*- $C_6H_4MeNH_2$ , *m*-4-xylydine,  $\psi$ -cumidine, or mesidine. The interconversion is represented:  $NR:N\cdot ONa$  (II)  $\rightleftharpoons$   $NR:N\cdot ONa$  (I). Application of (I) to dyeing, and to "diazotype" photographic printing, is discussed; good prints have been obtained using (I) from *p*- $C_6H_4BrNH_2$  or from *p*- $C_6H_4INH_2$ .

X. (I) may be rapidly prepared by adding solutions of diazonium salts to 1-6% NaOH heated to 100°, and keeping at 100° until (after a few min.) coupling power is completely lost ( $\beta$ - $C_{10}H_7OH$  paper). Yields are: from  $NH_2Ph$ , 29%; from its *m*- and *p*-Me, *p*-Br-, *p*-I-, and *m*- $NO_2$ -derivatives, 31, 8, 39, 52, and 61%; when 0.4 or 0.8% NaOH is used, yields are smaller.

XI. A historical review, summed up in favour of the structures:  $NR:NCl \rightarrow NR:N\cdot OH \rightarrow NR:N\cdot OK \rightleftharpoons NR:N\cdot OH$  (see Part IX). On this view, "(I)" ("antidiazotates" of Hantzsch) should be renamed "diazotates," and "(II)" ("syndiazotates" of Hantzsch) be renamed "diazoniates." The very small depressions of f.p. of aq. NaOH caused by diazonium salts (A., 1895, i, 661) support the view that slightly hydrolysed diazotates are formed, and are in contrast to the great depressions now observed with methylpyridinium and *o*-tolyltrimethylammonium iodides. An aq. solution of benzenediazoxycarbonamide (III) (A., 1922, i, 1071) [but not anhyd. (III)] reacts with Br to form a substance, m.p. 102–103°, decomposed by boiling  $H_2O$ . (III) heated in  $H_2O$  with Br, and treated with  $SO_2$ , yields an insol. substance, m.p. 222°, and an acid, m.p. 142° (decomp. to a substance, m.p. 136°), which couples with  $\beta$ - $C_{10}H_7OH$  and is regarded as benzenediazoxycarboxylic acid,  $Ph\cdot N_2O\cdot CO_2H$ , together with a substance, m.p. 75°. The action of NaOH on (I) is formulated:  $NPh\cdot N(O)\cdot CO\cdot NH_2 \rightarrow NPh\cdot N\cdot NH\cdot O \rightarrow NPh\cdot N\cdot OH \rightarrow NPh\cdot N\cdot ONa$ . (I) treated with aq. or conc.  $H_2SO_4$ , or with  $PCl_5$ , does not give  $PhNO_2$  [which would be expected if (I) were  $NPh(O)\cdot N\cdot CO\cdot NH_2$  as suggested by Angeli (A., 1917, i, 418)], but only, after prolonged action,  $PhOH$ .

E. W. W.

Identification of phenols with 1-chloro-2:4-dinitrobenzene. R. W. BOST and F. NICHOLSON (J. Amer. Chem. Soc., 1935, 57, 2368–2369).—Aryl 2:4-dinitrophenyl ethers are prepared by heating  $NaOAr$  (0.01 mol. in 5 c.c. of  $H_2O$ ) with 1:2:4- $C_6H_3Cl(NO_2)_2$  (0.01 mol. in 30 c.c. of 95% EtOH). The following are described: *Ph*, m.p. 69°; *o*-, m.p. 90°, and *m*-, m.p. 74°, -tolyl; *p*-tolyl, m.p. 33.5°; *thymyl*, m.p. 67°; *o*-anisyl, m.p. 97°;  $\alpha$ - $C_{10}H_7$ , m.p. 128°;  $\beta$ - $C_{10}H_7$ , m.p. 95°; *p*-diphenyllyl,

m.p. 118°; *m*-OH- $C_6H_4$ , m.p. 194° (lit. 184°); *eu*-genyl; *isoeugenyl*, m.p. 130°; 2:4-(OMe)(CHO) $C_6H_3$ ; *o*-, m.p. 142° (lit. 119°), *m*-, m.p. 138°, and m.p. 120° (lit. 114°),  $NO_2\cdot C_6H_4$ ; 6-chloro-*m*-tolyl, m.p. 112°; *o*- $C_6H_4I$ , m.p. 95°; *p*- $C_6H_4I$ ; *o*-, m.p. 99°, *m*-, m.p. 75°, and *p*-, m.p. 126°, *C.H.Cl*; 2:4- $C_6H_3Cl_2$ , m.p. 119°; 2:4:6- $C_6H_2Cl_3$ , m.p. 136°; *o*-, m.p. 89°, and *p*-, m.p. 141°,  $C_6H.Br$ ; 2:4- $C_6H_3Br_2$ , m.p. 135°; 2:4:6- $C_6H_2Br_3$ , m.p. 135°.

H. B.

*m*-2-Xylyl  $\alpha$ -naphthylcarbamate. C. D. HURD and M. A. POLLACK (J. Amer. Chem. Soc., 1936, 58, 181).—The xylenol obtained (A., 1932, 857) by pyrolysis of furfuraldehyde is 2:6- $C_6H_3Me_2OH$  ( $\alpha$ -naphthylcarbamate, m.p. 176.5°).

H. B.

Synthesis of alkyl- and aryl-cryptophenols. M. E. MCGREAL and J. B. NIEDERL (J. Amer. Chem. Soc., 1935, 57, 2625–2627).— $CMe_2Pr^{\beta}OH$  (1 mol.),  $PhOH$  (1 mol.), and  $ZnCl_2$  (1.5 mols.) at 180° give  $\beta$ -*p*-hydroxyphenyl- $\beta$ - $\gamma$ -dimethylbutane, m.p. 105° (45);  $CMe_2Bu^{\alpha}OH$  similarly affords  $\beta$ -*p*-hydroxyphenyl- $\beta$ -methylhexane, b.p. 280°/760 mm., but  $\beta\delta\delta$ -trimethylpentan- $\beta$ -ol yields *p*- $C_6H_4Bu^{\alpha}OH$  (I); the methylcyclohexanols give *p*-2-, m.p. 107° (50), -3-, m.p. 101° (105), and -4-, m.p. 108° (70), -methylcyclohexylphenols, but 4-*tert*.-octylcyclohexanol affords (I);  $CH_2PhOH$  yields *p*-benzylphenol;  $CH_2Ph\cdot CH_2OH$  or  $CHPhMeOH$  gives  $\alpha$ -phenyl- $\alpha$ -*p*-hydroxyphenylethane, m.p. 64° (40) (dehydration of the former presumably preceding addition of the  $PhOH$ );  $CPhMeEtOH$  affords  $\beta$ -phenyl- $\beta$ -*p*-hydroxyphenylbutane, b.p. 145–148°/2.5 mm., also prepared (method: A., 1935, 79) from  $PhOH$  and  $\beta$ -phenyl- $\Delta^{\beta}$ -butene;  $CPhMePr^{\beta}OH$  yields  $\beta$ -phenyl- $\beta$ -*p*-hydroxyphenyl- $\gamma$ -methylbutane, b.p. 157–160°/3 mm., also prepared from the appropriate phenylpentene. The nos. quoted in parentheses are the  $PhOH$ -coeffs. (using *Staph. aureus*).

H. B.

Reduction of isosafrole with sodium and ethyl alcohol. K. ONO and M. IMOTO (J. Chem. Soc. Japan, 1934, 55, 991–1001).—A mixture of *m*- and *p*- $C_6H_4PrOH$  is produced. Addition of active C increases the yield.

CH. ABS. (r)

Phenols of anthracene oil. O. KRUBER (Ber., 1936, 69, [B], 107–114).—The liquid products obtained by centrifuging a crude phenanthrene fraction, b.p. 320–340°, after extraction with NaOH and distillation of the extracted matter in vac., yielded *p*-hydroxydiphenyl, m.p. 163°. Similar treatment of crude  $C_{10}H_8$  press-cake yielded  $\beta$ - $C_{10}H_7OH$  and a diphenol,  $C_{16}H_{18}O_2$ , m.p. 135°, b.p. 341°/755 mm. [*Me\_2 ether*, b.p. 200–201°/15 mm., m.p. 85°; *diphenylurethane*, m.p. 199–200°; compound,  $C_{42}H_{36}O_4N_2$ , m.p. 192–193°, with  $CO(NHPh)_2$ ]. Separation of the phenols of the anthracene oil fraction, b.p. 340–370°, is rendered difficult by the presence of complex, non-phenolic substances with feebly acidic properties; it is best effected by repeated alternate extraction with NaOH and distillation of the extracted matter, whereby the complex materials are extensively decomposed. Distillation of the phenolic fraction over Zn dust or a Mo contact affords diphenylene oxide and fluorene. Further fraction-

ation and prolonged keeping of the individual fractions in PhMe at 0° causes the separation of a solid material which cannot be separated into its components by crystallisation. When treated with NaOH and Me<sub>2</sub>SO<sub>4</sub> it yields a mixture of ethers, non-separable by crystallisation, from which 2-methoxydiphenylene oxide (I), m.p. 98°, is isolated after partial oxidation with Na<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> in AcOH at 70°. Treatment of (I) with NH<sub>2</sub>Ph.HCl at 250° affords 2-hydroxydiphenylene oxide, b.p. 348°/758 mm., m.p. 142—143° (phenylurethane, m.p. 173°). The synthesis of (I) from 2-aminodiphenylene oxide is recorded. Treatment of the mother-liquors from (I) with NH<sub>2</sub>OH.HCl and BaCO<sub>3</sub> leads to the isolation of 2-methoxyfluorenoneoxime, m.p. 174° after softening, whence 2-methoxyfluorenone, m.p. 78°. Separation of the crude methylated product into its components can also be effected by Na at 180—200° but is complicated by many by-reactions. H. W.

**Phenylether series. IV. 4:4'-Dithioldiphenyl ether and related compounds.** C. M. SUTER and P. H. SCRUTCHFIELD (J. Amer. Chem. Soc., 1936, 58, 54—55).—Reduction (SnCl<sub>2</sub>, AcOH-HCl) of (p-SO<sub>2</sub>Cl-C<sub>6</sub>H<sub>4</sub>)<sub>2</sub>O (A., 1931, 616) gives 4:4'-dithioldiphenyl ether, m.p. 103—104° (Me<sub>2</sub> ether, m.p. 81—81.5°), converted by CH<sub>2</sub>Cl.CO<sub>2</sub>K into the 4:4'-dithioglycollic acid, m.p. 165—166° (chloride, converted by AlCl<sub>3</sub> into a red tar), which could not be cyclised by oleum or ClSO<sub>3</sub>H to a thionaphthen derivative.

(+)- and (-)-γ-Phenyl-α-methylallyl alcohols. J. KENYON, S. M. PARTRIDGE, and H. PHILLIPS (J.C.S., 1936, 85—88).—CHPh.CH<sub>2</sub>CHO and MgMeBr give dl-γ-phenyl-α-methylallyl alcohol (I), b.p. 129—131°/11 mm., m.p. 33° [p-nitrobenzoate, m.p. 58—59°; H phthalate (II), m.p. 92—93.5°, prepared by the action of o-C<sub>6</sub>H<sub>4</sub>(CO)<sub>2</sub>O on (I) (in C<sub>5</sub>H<sub>5</sub>N) or the Grignard complex], which could not be separated (distillation; partial fusion; crystallisation) into *cis*- and *trans*-forms. Recrystallisation (from EtOAc) of the cinchonidine salt of (II) affords the cinchonidine salt, m.p. 179° (decomp.), of (+)-γ-phenyl-α-methylallyl H phthalate (III), m.p. 68.5°, [α]<sub>5461</sub> +44.71° in CS<sub>2</sub>, -15.4° in EtOH (vals. for many solvents and different λ given). Hydrolysis of (III) with aq. Na<sub>2</sub>CO<sub>3</sub> gives (I); 5*N*-NaOH and subsequent crystallisation from CH<sub>2</sub>Cl<sub>2</sub>-light petroleum lead to the (+)-alcohol (IV), m.p. 61°, [α]<sub>5461</sub> +28.3° in CS<sub>2</sub> (p-xenylcarbamate, m.p. 179—180°; p-nitrobenzoate, m.p. 41°; acetate, b.p. 132—133°/9 mm.), reduced (Adams) to (-)-CH<sub>2</sub>Ph.CH<sub>2</sub>CHMe.OH (V) (phenylcarbamate, m.p. 47—48°) (J.C.S., 1914, 105, 1124). The recovered H phthalate [from (III)] gives the brucine salt, decomp. about 110°, of (-)-γ-phenyl-α-methylallyl H phthalate, m.p. 68.5°, [α]<sub>5461</sub> -44.53° in CS<sub>2</sub>, and thence (as above) the (-)-alcohol, m.p. 61°, [α]<sub>5461</sub> -28° in CS<sub>2</sub>. Comparison of the rotatory powers of (IV), (V), (-)-CHMeEt.OH, and (+)-CH<sub>2</sub>:CH:CHMe.OH shows that introduction of Ph [as in (IV) and (V)] causes [M] to be approx. doubled; the introduction of the Δ<sup>2</sup>-double linking doubles [M] and reverses the sign. H. B.

**Resolution of phenyl-*n*-propylcarbinol.** J. KENYON and S. M. PARTRIDGE (J.C.S., 1936, 128—

129).—CHPhPr.OH (H phthalate, m.p. 90—91°) is resolved through the quinidine salt, m.p. 168—169°, of the *d*-H phthalate, m.p. 53—54°, [α]<sub>5461</sub> -11.5° in Et<sub>2</sub>O, into the *d*-form, b.p. 115°/14 mm., m.p. 49°, [α]<sub>5461</sub> +52.2° in C<sub>6</sub>H<sub>6</sub>, and afterwards through the strychnine salt, m.p. 184—185° (decomp.), of the *l*-H phthalate, m.p. 52—53°, [α]<sub>5461</sub> -11° in Et<sub>2</sub>O, into the *l*-form, m.p. 48—49°, [α]<sub>5461</sub> -53.5°, [α]<sub>5893</sub> -45.9° in C<sub>6</sub>H<sub>6</sub> (cf. Levene and Marker, A., 1932, 1027). Vals. for other solvents and λ are given.

H. B.

**epialloCholesterol, a new isomeride of cholesterol.** E. A. EVANS, jun., and R. SCHOENHEIMER (J. Amer. Chem. Soc., 1936, 58, 182).—Reduction of cholestenone with Al(OPr<sup>i</sup>)<sub>3</sub> gives epiallocholesterol (I), m.p. 84°, [α]<sub>D</sub><sup>25</sup> +120.8° in C<sub>6</sub>H<sub>6</sub> (acetate, m.p. 82.5°), and an isomeride [pptd. by digitonin whereas (I) is not]. (I) is reduced (catalytically) to a mixture of epidihydrocholesterol and epicoprosterol, indicating that (I) contains C<sup>3</sup>-OH *trans* to C<sup>10</sup>-Me; an intense Rosenheim reaction also indicates that the double linking is between C<sup>4</sup> and C<sup>5</sup>. (I) is dehydrated by dil. HCl in 95% EtOH to a hydrocarbon, C<sub>27</sub>H<sub>44</sub>, m.p. 79°, [α]<sub>D</sub><sup>25</sup> -118.2° in C<sub>6</sub>H<sub>6</sub>, the absorption max. (244, 235, and 229 mμ) of which differ from those of cholesterolene (Heilbron *et al.*, A., 1928, 219). H. B.

**Androsterone and related sterols.** R. E. MARKER, F. C. WHITMORE, and O. KAMM (J. Amer. Chem. Soc., 1935, 57, 2358—2360).—α-Cholestyl chloride (I), m.p. 112°, is prepared (a) by reduction (H<sub>2</sub>, PtO<sub>2</sub>, AcOH) of cholesteryl chloride, (b) from epicholesterol (II) and PCl<sub>5</sub>, and (c) from β-cholestanol (III) and SOCl<sub>2</sub>; Walden inversion occurs in (a) and (c). (I) is hydrolysed (KOAc in valeric acid followed by EtOH-KOH) to (II). β-Cholestyl chloride, m.p. 102—103°, obtained from (II) and SOCl<sub>2</sub> or (III) and PCl<sub>5</sub>, is similarly hydrolysed to (III). Oxidation (CrO<sub>3</sub>, AcOH) of (I) gives α-chlorocholelanic acid, m.p. 174—175°, and α-chloroandrosterone, m.p. 170—171° (Butenandt and Dannenbaum, A., 1935, 413; cf. Ruzicka *et al.*, *ibid.*, 1125). H. B.

**Alkaline halogenation. Bromination of sodium benzoate.** P. L. HARRIS and J. C. SMITH (J.C.S., 1936, 168; cf. A., 1934, 405).—BzOH (61 g.) in aq. NaOBr [2 litres from NaOH (40 g.) and Br (80 g.)] at 35°/7 days gives approx. 5 g. each of *o*-, *m*-, (I), and *p*-C<sub>6</sub>H<sub>4</sub>Br.CO<sub>2</sub>H; the results vary owing to rapid decomp. of NaOBr. Use of 2 equivs. of NaOH (*i.e.*, NaOBz:NaOBr=1) almost inhibits bromination. In agreement with Stark (A., 1910, i, 234), (I) is the main product from BzOH and HOBr in H<sub>2</sub>O. H. B.

**Syntheses in the anæsthetic group. I.** G. SANNA (Annali Chim. Appl., 1935, 25, 638—643).—*Et p-chloroacetamidobenzoate*, m.p. 115°, is prepared by treating anæsthesine (I) in C<sub>6</sub>H<sub>6</sub> with CH<sub>2</sub>Cl.COCl, and is converted (NHMe<sub>2</sub>) into *Et p-dimethylglycylamidobenzoate* (II), m.p. 95° (hydrochloride, m.p. 193°) and (NH<sub>4</sub>Et<sub>2</sub>) into the corresponding Et<sub>2</sub> compound (III), m.p. 115° (hydrochloride, m.p. 211°). (II) and (III) are more sol. than (I) in H<sub>2</sub>O, and have anæsthetic properties, which are being examined. E. W.

**Preparation of α-naphthoic acid.** D. J. and F. C. WHITMORE (J. Amer. Chem. Soc., 1935, 57,

2727).— $\alpha$ -C<sub>10</sub>H<sub>7</sub>·CO<sub>2</sub>Et, obtained in 70% yield from  $\alpha$ -C<sub>10</sub>H<sub>7</sub>·MgBr and Et<sub>2</sub>CO<sub>3</sub>, is hydrolysed to the acid (yield > 90%). H. B.

**Synthesis of alkeines derived from O-phenyl-lactic and -mandelic acid.** E. PLÁZEK, Z. RODEWALD, and D. KRZYŻANIAK (Rocz. Chem., 1935, 15, 360—364).—O-Phenylmandetyl chloride, b.p. 135°/0.6 mm., yields the *tropyl* ester, b.p. 208°/1 mm. (*picrate*, m.p. 171°; *picrolonate*, m.p. 187°), with tropine, and  $\beta$ -dimethylaminoethyl O-phenylmandelate, b.p. 148—150°/0.2 mm. (*picrolonate*, m.p. 141—142°), with NEt<sub>2</sub>·CH<sub>2</sub>·CH<sub>2</sub>·OH. KOPh and CHMeBr·CO<sub>2</sub>Me (2 hr.; 100°), followed by hydrolysis of the product with EtOH-KOH, yield O-phenyl-lactic acid (I), m.p. 114°, the *chloride*, b.p. 115°/20 mm., of which affords the *tropyl*, b.p. 140—150°/0.6 mm. (*picrate*, m.p. 175°; *picrolonate*, m.p. 200—202°), and  $\beta$ -dimethylaminoethyl esters of (I), m.p. 75° (*picrate*, m.p. 113°; *picrolonate*, m.p. 148°). R. T.

**Dehalogenation of  $\beta$ -bromo-acids.** IV.  $\beta$ -Bromophenylpyruvic acid. B. SOBIN and G. B. BACHMAN (J. Amer. Chem. Soc., 1935, 57, 2458—2460).— $\beta$ -Bromophenylpyruvic acid (I), m.p. 103—104° (from CH<sub>2</sub>Ph·CO·CO<sub>2</sub>H and Br in CCl<sub>4</sub>), is converted by boiling with H<sub>2</sub>O or shaking with Ag<sub>2</sub>O in H<sub>2</sub>O into CH<sub>2</sub>Ph·CO<sub>2</sub>H (II) (yield 77 and 94%, respectively); the following reactions are considered to occur: CHBrPh·CO·CO<sub>2</sub>H  $\rightarrow$  CO<sub>2</sub> + HBr + CHPh·C'O; CHPh·C'O + H<sub>2</sub>O  $\rightarrow$  CH<sub>2</sub>Ph·CO<sub>2</sub>H. CH<sub>2</sub>Ph·CO<sub>2</sub>Et is similarly obtained in 36% yield from (I) and Ag<sub>2</sub>O in EtOH. (I) and aq. Na<sub>2</sub>CO<sub>3</sub> give benzoyl-carbinol (III) (by rearrangement of the intermediate OH·CHPh·CHO); with aq. NaHCO<sub>3</sub>, a mixture of (II) and (III) and a little of an acid, C<sub>23</sub>H<sub>15</sub>O<sub>5</sub>, m.p. 218—219° (Ac derivative, m.p. 162—163°), result. Tars (free from CHPh·C'O) are produced from (I) and C<sub>2</sub>H<sub>5</sub>N or NPhMe<sub>2</sub>. H. B.

**General reaction for the preparation of keto-acids, unsaturated acids, and disubstituted lactones.** II. G. KOMPPA and W. ROHRMANN (Annalen, 1936, 521, 227—242).—*apo*Camphoric anhydride (I) (1 mol.) and MgMeI (1 mol.) at -15° (cf. A., 1934, 650) give, after esterification, *Et cis-3-acetyl-2-dimethylcyclopentane-1-carboxylate*, b.p. 122—123°/11 mm., isolated as its *semicarbazone*, m.p. 142—142.5°, not identical with the *trans-ester* [*semicarbazone*, m.p. 196—200° (decomp.); *semicarbazone* of the free acid, m.p. 191° (decomp.)] obtained by Winzer's method (A., 1890, 1152) by the action of LiNa(CO<sub>2</sub>Et)<sub>2</sub> on (I) in C<sub>6</sub>H<sub>6</sub> to give *malonylapo-camphoric anhydride*, m.p. 63.5—64°, b.p. 216°/12 mm., and subsequent hydrolysis with NaOEt-EtOH. With 2 mols. of MgMeI (I) affords *dimethylapo-campholide* (45% yield), m.p. 102—103°, and *3-isopropylidene-2:2-dimethylcyclopentane-1-carboxylic acid*, (35% yield), m.p. 103—104° (gives 2:2-dimethylcyclopentanone-3-carboxylic acid on ozonolysis). Similarly *d*-camphoric anhydride (II) with MgMeI (1 mol.) gives *Et cis-3-acetyl-2:2:3-trimethylcyclopentane-1-carboxylate*, b.p. 133—135°/8 mm. (*semicarbazone* m.p. 177°, hydrolysed to the acid, +H<sub>2</sub>O, 76—78° (*semicarbazone*, m.p. 223—224°), probably identical with the acid, m.p. 73°, obtained

by Quadrat-i-Khuda (A., 1930, 471), but different from Winzer's acid (*loc. cit.*), which is *cis-3-acetyl-1:2:2-trimethylcyclopentane-1-carboxylic acid* (IV) (*semicarbazone*, m.p. 218°, indefinite). With 2 mols. of MgMeI (II) gives *dimethylcampholide* and *3-isopropenyl-1:2:2-trimethylcyclopentane-1-carboxylic acid* (V), the m.p., 68.5—70.5°, of which (Komppa. A., 1908, i, 353) is raised to 87—88° by repeated crystallisation, probably by conversion into the *3-isopropylidene acid* (VI); ozonolysis of (V) gives a *3-acetyl-1:2:2-trimethylcyclopentane-1-carboxylic acid* (*semicarbazone*, m.p. 220—221°) not identical with either (III) or (IV), whereas (VI) gives an indefinite oil with O<sub>3</sub>. The results of Houben *et al.* (A., 1908, 539) on the interaction of CH<sub>2</sub>Ph·MgCl on (II) are confirmed and, in addition, are isolated an *Et phenyl-acetyltrimethylcyclopentanecarboxylate*, b.p. 217—218° [converted into the bicyclic compound (VII) by hydrolysis], and an *Et  $\beta$ -phenyl- $\alpha$ -benzylethylidenetrimethylcyclopentanecarboxylate*, b.p. 230—234°/9 mm. (*acid*, m.p. 166—167°). *Santenic anhydride* (VIII) with MgMeI gives *cis-3-acetyl-2:3-dimethylcyclopentane-1-carboxylic acid*, m.p. 63—65° (*semicarbazone*, m.p. 218°), not identical with *cis-3-acetyl-1:2-dimethylcyclopentane-1-carboxylic acid*, m.p. 95—96° (*semicarbazone*, m.p. 219°), obtained by Winzer's method. With 2 mols. of MgMeI (VIII) affords *dimethylsantolide*, b.p. 136—138°/15 mm., and a trace of an unsaturated acid.

J. W. B.

**Preparation of tetrachlorophthalic acid.** J. S. SALKIND and M. BELIKOVA (J. Appl. Chem. Russ., 1935, 8, 1210—1213).—*o*-C<sub>6</sub>H<sub>4</sub>(CO)<sub>2</sub>O at 240—250° and Cl<sub>2</sub> (in presence of 3% of Fe) yield tetrachlorophthalic acid in 90—95% yield. The product loses H<sub>2</sub>O of crystallisation (1.5 mols.) at 100°, and is converted into the anhydride at 110°. R. T.

**Lithium phthalate.**—See this vol., 282.

**Synthesis of hydrogenated phenanthrenes.**

E. E. GRUBER and R. ADAMS (J. Amer. Chem. Soc., 1935, 57, 2555—2556; cf. Barnett and Lawrence, A., 1935, 1243).—1:1'-Dihydroxy-1:1'-dicyclohexyl (from cyclohexanone, Mg, and HgCl<sub>2</sub> in C<sub>6</sub>H<sub>6</sub>) is dehydrated (10% H<sub>2</sub>SO<sub>4</sub>) to di- $\Delta^{1,1'}$ -cyclohexene, b.p. 101—102°/5.5 mm., which with maleic anhydride in C<sub>6</sub>H<sub>6</sub> gives the anhydride, m.p. 122.5—123.5°, of *dodecahydrophenanthrene-9:10-dicarboxylic acid*, m.p. 242° (Maquenne block) (*imide*, m.p. 182—183°), and with CH<sub>2</sub>CH·CHO in C<sub>6</sub>H<sub>6</sub> at 50—60° affords *dodecahydrophenanthrene-9-aldehyde*, b.p. 136—137°/4 mm. (*semicarbazone*, m.p. 179—180°). H. B.

**Synthesis of 1-methylcyclopentane-1:3-dicarboxylic acid (1-methylnorcamphoric acid).** N. J. TOIVONEN, A. JOHN, E. SAINIO, and T. KUUSINEN (Suomen Kem., 1935, 8, B, 46—47).—Et<sub>3</sub> 2-methylcyclopentanone-2:4:5-tricarboxylate with glycerol-H<sub>2</sub>O at 170—200° affords Et<sub>2</sub> 2-methylcyclopentanone-2:4-dicarboxylate, b.p. 153—156°/11 mm., which with K-Hg in EtOH-dil. H<sub>2</sub>SO<sub>4</sub> gives Et<sub>2</sub> 2-methylcyclopentan-1-ol-2:4-dicarboxylate, b.p. 126—128°/0.5 mm. [*acid*, m.p. 172—174°, converted by HBr followed by Zn in AcOH-HCl into *cis*- (cf. this vol., 339) and *trans*-1-methylcyclopentane-1:3-dicarboxylic acid, m.p.

114—115°, the former of which with  $\text{PCl}_5$  and excess of Br gives the 3-Br-derivative, m.p. 136—138°].

J. L. D.

**Condensation of bindone with  $\alpha$ -halogeno-carboxylic esters.** G. WANAG (Ber., 1936, 69, [B], 189—194; cf. A., 1935, 623).—Bindone [(I)  $\text{X}=\text{R}=\text{H}$ ] condenses with  $\text{CH}_2\text{Cl}\cdot\text{CO}_2\text{Et}$  in boiling EtOH containing  $\text{K}_2\text{CO}_3$  to *Et bindonylacetate* [(I)  $\text{X}=\text{H}$ ;  $\text{R}=\text{CH}_2\cdot\text{CO}_2\text{Et}$ ], m.p. 109°, converted by Br in boiling

$\text{CHCl}_3$  into *Et bromobindonylacetate* [(II) (I)  $\text{X}=\text{Br}$ ;  $\text{R}=\text{CH}_2\cdot\text{CO}_2\text{Et}$ ], m.p.

153°, by fuming  $\text{HNO}_3$  in boiling AcOH into *Et nitrobindonylacetate* [(I)  $\text{X}=\text{NO}_2$ ;  $\text{R}=\text{CH}_2\cdot\text{CO}_2\text{Et}$ ], m.p. 154—155°, and hydrolysed by acid or alkali to *bindonylactic acid*, m.p. 242—244°. Treatment of (II) with conc. HCl in AcOH affords (?) *indandionylene- $\alpha$ -naphthaquinone* [(I) with  $\text{CH}:\text{CH}$  for CXR], m.p. 310—312°. Analogously, (I) and  $\text{CHBrMe}\cdot\text{CO}_2\text{Et}$  yield *Et  $\alpha$ -bindonylpropionate* [(I)  $\text{X}=\text{H}$ ;  $\text{R}=\text{CHMe}\cdot\text{CO}_2\text{Et}$ ], m.p. 126—127°, whence *Et  $\alpha$ -nitrobindonylpropionate*, m.p. 154—155°, and  *$\alpha$ -bindonylpropionic acid*, m.p. 230°. *Et bindonylphenylacetate* [(I)  $\text{X}=\text{H}$ ;  $\text{R}=\text{CHPh}\cdot\text{CO}_2\text{Et}$ ], m.p. 153°, *Et nitrobindonylphenylacetate*, m.p. 158—159°, and *bindonylphenylacetic acid*, m.p. 234°, are obtained with  $\text{CHBrPh}\cdot\text{CO}_2\text{Et}$ . Treatment of (I) with  $\text{CHCl}(\text{CO}_2\text{Et})_2$  leads to *trans-dibindonylene*, production of which does not appear to be due to simple dehydrogenation, since it is also formed when  $\text{Pr}^{\beta}\text{I}$  or  $\text{C}_2\text{H}_4\text{Br}_2$  is used and (in small amount) when  $\text{MeI}$  is employed; it is suggested that these substances accelerate autoxidation.

H. W.

#### Mechanism of the Perkin-Oglialoro synthesis.

(SIGNA.) M. BAKUNIN and D. PECCERILLO (Gazzetta, 1935, 65, 1145—1161).—The yield of *o*-nitrocinamic acid (I) from the reaction (at 90°) between *o*- $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CHO}$  (II) and various metallic salts of  $\text{CH}_2\text{Ph}\cdot\text{CO}_2\text{H}$  (III), in presence of  $\text{Ac}_2\text{O}$ , increases in the order  $\text{Ba} < \text{Li} < \text{Na} < \text{K} < \text{Rb}$ .  $\text{NH}_4$  and  $\text{NH}_3\text{Ph}$  salts do not give (I). With (II) and the anhydride of (III), the catalytic action of bases etc. is in the order  $\text{NHET}_2 < \text{C}_5\text{H}_{11}\text{N} < \text{NaOAc} < \text{NMe}_3 < \text{NEt}_3$ . From (II) and (III) in absence of  $\text{Ac}_2\text{O}$ , or of catalyst, no (I) is formed; the effects of various bases in presence of  $\text{Ac}_2\text{O}$ , and of various anhydrides in presence of  $\text{NEt}_3$ , are tabulated. (II) and (III) react in presence of  $\text{NaOBz}$ .  $\text{CH}_2\text{Ph}\cdot\text{CH}\cdot\text{CO}_2\text{Et}$  does not react with (II). *o*- $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CH}(\text{OAc})_2$  with  $\text{CH}_2(\text{CO}_2\text{H})_2$  yields *o*- $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CH}:\text{C}(\text{CO}_2\text{H})_2$ , but does not react appreciably with (III). The reaction  $\text{Ac}_2\text{O} + 2\text{CH}_2\text{Ph}\cdot\text{CO}_2\text{M} \rightarrow (\text{CH}_2\text{Ph}\cdot\text{CO}_2)_2\text{O} + 2\text{MOAc}$  has been shown to take place, and to depend on the nature of M (Na, Li, Ba), and on temp. The effect of inorg. salts as catalysts is ascribed to formation of  $\text{MOAc}$ ; KI, which does not yield  $\text{KOAc}$ , is not a catalyst. Mol. compounds are formed between anhydrides or acids, and salts of the same (or perhaps even of a different) acids, e.g., the compound  $\text{CH}_2\text{Ph}\cdot\text{CO}_2\text{H}\cdot\text{CH}_2\text{Ph}\cdot\text{CO}_2\text{Na}$  (IV), m.p. 95° (stable in org. solvents). (IV) reacts with (II) in the presence, but not in the absence, of  $\text{Ac}_2\text{O}$  or  $\text{Bz}_2\text{O}$ .  $\text{CH}_2\text{Ph}\cdot\text{CO}_2\text{Na}$  and  $\text{Ac}_2\text{O}$  react to form a mol. com-

pound, m.p. 60°, together with (IV);  $\text{AcCl}$  reacts similarly, as do other substances. It is concluded that the Perkin synthesis depends on the intermediate formation of acid-salt or anhydride-salt compounds (which are decomposed by  $\text{H}_2\text{O}$ ), on their stability at the temp. of reaction, and their solubility in the medium, and on the homogeneous presence in the formation of substances capable of absorbing  $\text{H}_2\text{O}$ . The formation of Ac and imide derivatives of aldehydes impedes the reaction.

E. W. W.

**Removal of hydrogen and acid radicals from organic compounds by bases. II. Removal of acetic acid from acetylaldoximes by alkalis.** C. R. HAUSER and E. JORDAN (J. Amer. Chem. Soc., 1935, 57, 2450—2456; cf. A., 1934, 73).—Acetyl- $\alpha$ - and - $\beta$ -araldoximes undergo the same types of reaction with alkalis; the oxime is formed by hydrolysis and the ArCN by elimination (which occurs more readily with the  $\beta$ -derivatives) of AcOH. The yields of products depend on the relative rates of the two (competing) reactions. Acetyl- $\beta$ -*p*-methoxy-, -3:4-methylenedioxy- (I), and -*p*-nitro-benzaldoximes with 2*N*-NaOH give mixtures of ArCN (predominates at 30°) and the  $\alpha$ -oxime (II) (predominates at 0°); the first two with aq. 10%  $\text{Na}_2\text{CO}_3$  at 0° or 30° give ArCN and a little (II) (cf. loc. cit.). Hydrolysis (2*N*-NaOH) of acetyl- $\alpha$ - (III), -*m*-, and -*p*-nitro-, -*p*-methoxy-, and -3:4-methylenedioxy- (IV) -benzaldoximes, prepared by a modification of Brady and Dunn's method (J.C.S., 1, 13, 103, 1619), at 30° and 97—100° gives (usually) the  $\alpha$ -oxime (V) and a little  $\text{ArCO}_2\text{H}$  at 61—64° (III) affords an appreciable amount *o*- $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CN}$ . (IV) and acetyl- $\alpha$ -chloro-, -*p*-methoxy-, and -*m*-nitro-benzaldoximes with  $\text{KNH}_2$  in liquid  $\text{NH}_3$  give ArCN (major product) and (V) the first three with boiling 2*N*-EtOH-NaOEt afford mainly (I) (as Na salts). (I) is hydrolysed more readily than (IV) by an excess of  $\text{Na}_2\text{CO}_3$  in aq. COM.e<sub>2</sub>.

#### Reactions of aldoxime derivatives with bases.

**II. Reactions of carbethoxy- $\alpha$ -benzaldoximes with sodium hydroxide.** C. R. HAUSER, E. JORDAN, and R. O'CONNOR (J. Amer. Chem. Soc., 1935, 57, 2456—2458).—Carbethoxy- $\alpha$ -benzaldoxime and its *o*- (I), *m*- (II), and *p*-nitro-, *o*- and *p*-chloro-, *o*- and *p*-methoxy- (III), and 3:4-methylenedioxy derivatives with 2*N*-NaOH give mixtures of the corresponding  $\alpha$ -oxime (IV) [predominates at 30°; except for (I) and ArCN (or  $\text{ArCO}_2\text{H}$ ) [the yield at 97—100° is > at 30° and often exceeds that of (IV)]] and ArCN (or  $\text{ArCO}_2\text{H}$ ) [the yield at 97—100° is > at 30° and often exceeds that of (IV)]. The yields of ArCN are generally > those from the acetyl- $\alpha$ -araldoximes (preceding abstract). (II) and (III) with  $\text{KNH}_2$  in liquid  $\text{NH}_3$  give ArCN and a little (IV). Some of the above  $\text{CO}_2\text{Et}$  derivatives are wrongly described as  $\beta$ -isomerides by Brady and McHugh (J.C.S., 1923, 123, 1190).

**Derivatives of dihydrovanillin. Catalytic hydrogenation of nitrostyrenes.** (A) O. S. CHALES. (B) K. MAURER (J. pr. Chem., 1936, [ii], 144, 214—215, 216).—Concerning priority (A., 1935, 1232, 1497).

**Iodine substitution products of vanillin and their derivatives.** L. C. RAIFORD and E. H. WELLS

(J. Amer. Chem. Soc., 1935, 57, 2500—2503).—2-Aminovanillin is converted (Sandmeyer) into 2-iodovanillin (I), m.p. 155—156° [Ac derivative, m.p. 70—72°; oxime (+0.5H<sub>2</sub>O), softens ca. 122°, m.p. (anhyd.) 142.5—143.5°; semicarbazone, m.p. 199—200°; p-nitrophenylhydrazone, m.p. 211—212°; benzidine condensation product, decomp. ca. 232—233°], methylated (Me<sub>2</sub>SO<sub>4</sub>, aq. KOH) to 2-iodo-3:4-dimethoxybenzaldehyde, m.p. 82°. 5-Aminovanillin (hydrochloride; stannichloride; ON-Ac, m.p. 174—176°, and ON-Bz, m.p. 161—162°, derivatives), prepared by reduction (SnCl<sub>2</sub>, conc. HCl, EtOH) of the NO<sub>2</sub>-compound, similarly gives 5-iodovanillin, m.p. 179—180° [Ac (II), m.p. 105—106°, and Bz, m.p. 135.5—136.5°, derivatives; oxime, m.p. 178—179°; semicarbazone, m.p. 205—205.5°; p-nitrophenylhydrazone, m.p. 242—243° (decomp.); benzidine condensation product, m.p. 232° (decomp.); Me ether, m.p. 69—70°], which is identical with the iodovanillin of Carles (A., 1872, 708). (II) or 5-iodo-4-acetoxy-3-methoxybenzylidene diacetate, m.p. 132—133°, with fuming HNO<sub>3</sub> at < gives derivative, m.p. 124—125°, of 5-iodo-2-nitrovanillin, m.p. 146—147° [oxime, m.p. 128—129°; semicarbazone, m.p. 187—188° (decomp.); p-nitrophenylhydrazone, (+0.5EtOH), m.p. 228—230° (decomp.); benzidine condensation product], reduced [Fe(OH)<sub>2</sub>, aq. NH<sub>3</sub>] to 5-iodo-2-aminovanillin (III), m.p. 155°. (I) and I in AcOH-NaOAc give 2:5-di-iodovanillin, m.p. 200° [Ac derivative, m.p. 127—128°; oxime, m.p. 174.5—175.5°; semicarbazone, m.p. 235° (decomp.); p-nitrophenylhydrazone, m.p. 252—253° (decomp.); benzidine condensation product; Me ether, m.p. 94°], also prepared (Sandmeyer) from (III). H. B.

**Synthesis of dicyclo-[1:2:3]-octanone and dicyclo-[1:2:3]-octane.** G. KOMPPA, T. HIRN, W. ROHRMANN, and S. BECKMANN (Annalen, 1936, 521, 242—261).—The following methods of prep. of hexahydrohomoisophthalic acid (I) (A., 1904, i, 60) have been investigated. (a) Homoisophthalic acid (II), m.p. 185° [diamide, m.p. 228°; Et, b.p. 175°/12 mm., and Me, b.p. 152—153°/10 mm., esters; Ba (+2H<sub>2</sub>O), Ag, Cd (+2H<sub>2</sub>O), and Zn (+0.66H<sub>2</sub>O) salts], is reduced by Na-Hg-NaOH to its H<sub>2</sub>-derivative (III) (Br<sub>2</sub>-derivative, m.p. 193—194°), which with HBr-AcOH at 100° gives the bromohexahydro-acid, m.p. 283° (decomp.) (and a substance, m.p. 157—158°), converted by Ag<sub>2</sub>O in EtOH into an unsaturated acid, C<sub>9</sub>H<sub>12</sub>O<sub>4</sub>, m.p. 141—143°, and reduced (Na-Hg) to (?) trans-hexahydrohomoisophthalic acid (IV), m.p. 156—158° [diamide, m.p. 277—278° (decomp.); Ag and Ba salts]. (b) Direct reduction of (III) with H<sub>2</sub>-Pd, or, better, direct catalytic reduction (Skita) of (II) (85% yield) is the best method of prep. (c) Reduction of (II) with Na-C<sub>5</sub>H<sub>11</sub>·OH gives a mixture, m.p. 120—127°, of stereoisomerides of (I). (d) cycloHexanone-3-carboxylic acid, obtained from m-OH·C<sub>6</sub>H<sub>4</sub>·CO<sub>2</sub>H (Einhorn et al., A., 1896, i, 530), with CH<sub>2</sub>Br·CO<sub>2</sub>Et-Zn and dehydration of the OH-ester with NaHSO<sub>4</sub> at 120—140°, gives the Et<sub>2</sub> ester, b.p. 151—156°/16 mm., of (III), reduced (Skita) to the Et ester, b.p. 138—144°/8 mm., of (I). (e) (IV) is obtained by condensation of Et 3-bromocyclohexane-1-carboxylate

with either CHNa(CO<sub>2</sub>Et)<sub>2</sub> or CN·CHNa·CO<sub>2</sub>Et and complete hydrolysis of the products. Reduction of hexahydroisophthalic anhydride with H<sub>2</sub>-Ni at 280—290° affords the lactone, b.p. 111—113°/8 mm f p -5° to -10°, of 3-hydroxymethylcyclohexane-1-carboxylic acid, also obtained by the action of I at 150° on the Ag salt of (IV). dicyclo-[1:2:3]-Octanone (V) (loc. cit.) [oxime, m.p. 66—67°; semicarbazone, m.p. 183—183.5° (corr.), and not 189—190° as previously recorded] is best obtained by distillation of the Ca salt of (IV). Oxidation of (V) with HNO<sub>3</sub> at 50° gives cis-hexahydroisophthalic acid, and reduction (Na-EtOH) affords dicyclo-[1:2:3]-octanol, b.p. 200—205°, m.p. 170° (corr.) [phenylurethane, m.p. 133° (corr.)], the chloride, b.p. 73—75°/14 mm., m.p. 43—45°, of which is reduced (Na-EtOH) to dicyclo-[1:2:3]-octane, m.p. 133—134°.

J. W. B.

**Preparation of m-nitroacetophenone.** V. G. MORGAN and H. B. WATSON (J.S.C.I., 1936, 55, 29—30T).—A method of nitration, using HNO<sub>3</sub>-H<sub>2</sub>SO<sub>4</sub>, is described, differing in some details from the procedure given in "Organic Syntheses," 1930, 10, 74, and leading to a better yield of a very pure product. The m.p. of m-nitroacetophenone is 79.5° (corr.).

**Synthesis of mixed acetones by means of ethyl malonate.** A. GIACALONE [in part with F. Russo] (Gazzetta, 1935, 65, 1127—1138).—Acyl chlorides react with CHNa(CO<sub>2</sub>Et)<sub>2</sub> (I) to form acyl compounds of type R·CO·CH(CO<sub>2</sub>Et)<sub>2</sub> (II), and acyl derivatives of the enolic form of these, viz., R·CO<sub>2</sub>·CR'C(CO<sub>2</sub>Et)<sub>2</sub> (II). (II) and (III) with NH<sub>2</sub>Ph, NHPh·NH<sub>2</sub>, or NH<sub>2</sub>OH yield CH<sub>2</sub>(CO<sub>2</sub>Et)<sub>2</sub> and R·CO·NHR'. BzCl and (I) give Et<sub>2</sub> benzoylmalonate, b.p. 198°/8 mm., and dibenzoylmalonate, m.p. 45°, b.p. 249°/6 mm. With NHPh·NH<sub>2</sub> these yield NHPh·NHBz, new m.p. 170—171°; both are hydrolysed to CPhMe. 6-Amino-3-methylacetophenone (IV), m.p. 50—51°, is prepared [with a view of synthesising 2-(4'-amino-m-tolyl)-4:6-dimethylquinoline (cf. A., 1935, 758)] as follows. 4-Nitro-m-toluic acid (V) (this vol., 69) is converted into the chloride, m.p. 45—46°, and this combined with (I) to form Et<sub>2</sub> 4-nitro-m-toluoyle- (VI), sol. in aq. NaOH, and di-(4-nitro-m-toluoyle)-malonate (VII), m.p. 106—107°, insol. in aq. NaOH. (V) is hydrolysed (80% H<sub>2</sub>SO<sub>4</sub>) to 6-nitro-3-methylacetophenone (VIII), and (VI) to (V) and (VIII). (VIII) is then reduced (Sn-HCl) to the stannichloride, (C<sub>9</sub>H<sub>4</sub>ON<sub>2</sub>)<sub>2</sub>·H<sub>2</sub>SnCl<sub>6</sub>, m.p. 187° (decomp.), of (I), with the stannichloride, m.p. 215° (decomp.), of 4-amino-m-tolylmethylcarbinol, m.p. 35°. 2-Nitro-m-toluic acid (IX) similarly yields, through its chloride, m.p. 82—83°, Et<sub>2</sub> 2-nitro-m-toluoyle- (X), m.p. 73°, and di-(2-nitro-m-toluoyle)-malonate (XI), m.p. 134—135°. (X) is hydrolysed to 2-nitro-3-methylacetophenone (XII), m.p. 85°, and (XI) to (IX) and (XII). (XII) is reduced to the stannichloride, m.p. 208°, of 2-amino-3-methylacetophenone.

E. W. W.

**Autoxidation of ketones.** S. S. JENKINS (J. Amer. Chem. Soc., 1935, 57, 2733).—o-C<sub>6</sub>H<sub>4</sub>Cl·CO<sub>2</sub>H and PhCHO are formed when o-C<sub>6</sub>H<sub>4</sub>Cl·CO·CH<sub>2</sub>Ph is kept. Similar autoxidation occurs with several ketones of the type COR·CH<sub>2</sub>Ph. H. B.

**Reaction between (A) phenyl  $\alpha\beta$ -dibromo- $\beta$ -phenylethyl ketone and azides, (B) phenyl  $\alpha\beta$ -dibromo- $\beta$ -*m*-nitrophenylethyl ketone and sodium azide.** V. A. KUZMIN and N. I. ZEMLIANSKI (Mem. Inst. Chem. Ukrain. Acad. Sci., 1935, 2, 183—190, 191—194).—(A)  $\text{NaN}_3$  and  $\text{CHPhBr}\cdot\text{CHBr}\cdot\text{COPh}$  in aq.  $\text{COMe}_2$  (12 hr. at 60—65°) yield a Br-containing oil, and a monoazide of Ph styryl ketone, m.p. 64—65°, both decomposed by  $\text{H}_2\text{SO}_4$  with evolution of  $\text{N}_2$ .

(B)  $m\text{-NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CHBr}\cdot\text{CHBr}\cdot\text{COPh}$  and  $\text{NaN}_3$  in aq. EtOH or  $\text{COMe}_2$  (12—14 hr. at 65—70°) afford a monoazide, m.p. 76—77° (decomp.) of Ph 3-nitro-styryl ketone. R. T.

**New route to hydroaromatic ketones related to anthracene and phenanthrene.** J. W. COOK, C. L. HEWETT, and C. A. LAWRENCE (J.C.S., 1936, 71—80).—2-Chlorocyclohexanol and  $\text{CH}_2\text{Ph}\cdot\text{MgCl}$  (I) lead (by ring-contraction) to cyclopentylcarbinol, b.p. 120° (bath)/0.1 mm., m.p. 30° (3:5-dinitrobenzoate, m.p. 100.5—101.5°), oxidised ( $\text{CrO}_3$ , AcOH) to phenylacetylcyclopentane (semicarbazone, m.p. 117—118°). cycloHexene oxide (II) and (I) give 2-benzylcyclohexanol (III), m.p. 76.5—77.5° (3:5-dinitrobenzoate, m.p. 133—135°) (oxidised to 2-benzylcyclohexanone), and a mixture (A) of *cis*- and *trans*-2-chlorocyclohexanols. The  $\text{Mg}(\text{CH}_2\text{Ph})_2$  present in the Grignard reagent thus appears to be more reactive than the  $\text{CH}_2\text{Ph}\cdot\text{MgCl}$  [responsible for the production of (A)] towards (II). 2-Phenylcyclohexanol (IV), b.p. 153—154°/16 mm., m.p. 56—57° (lit. 54—55°) (3:5-dinitrobenzoate, m.p. 121—121.5°), prepared from (II) and LiPh in  $\text{Et}_2\text{O}$  and  $\text{N}_2$ , is oxidised ( $\text{CrO}_3$ , AcOH) to  $\delta$ -benzoylvaleric acid and 2-phenylcyclohexanone (V). The poor yield of (IV) from (II) and  $\text{MgPhBr}$  (Bedos, A., 1926, 508) is due to cyclopentylcarbinol formation.  $\alpha\text{-C}_{10}\text{H}_7\text{Li}$  and (II) afford 2-1'-naphthylcyclohexanol, b.p. 183°/1 mm., m.p. 129—130° (3:5-dinitrobenzoate, m.p. 162—163°; phenylcarbamate, m.p. 134—135°), dehydrated ( $\text{ZnCl}_2$  at 160—170°) to 1-naphthyl- $\Delta^1$ -cyclohexene, m.p. 46° (lit. 36°), also prepared by Weiss and Woidich's method (A., 1926, 509), and from the alcohol and  $\text{PBr}_3$  in cold  $\text{CCl}_4$ .  $\text{CH}_3\text{Br}\cdot\text{CO}_2\text{Et}$ , (V), and Zn in  $\text{C}_6\text{H}_6$  give *Et* 1-hydroxy-2-phenylcyclohexylacetate, b.p. 146—154°/0.8 mm. (free acid, m.p. 128—129°), dehydrated ( $\text{SOCl}_2$ ,  $\text{Et}_2\text{O}$ ,  $\text{C}_2\text{H}_5\text{N}$  at 0°) to the *Et* ester, b.p. 123—125°/0.8 mm., of 2-phenyl- $\Delta^1$ -cyclohexenylacetic acid (VI), b.p. 150—155°/0.4 mm., m.p. 92.5—93.5°. Reduction ( $\text{H}_2$ , Pd-black, AcOH) of (VI) affords 2-phenylcyclohexylacetic acid (VII), m.p. 168—170°, and an impure isomeride (?) (cf. below) [converted by conc.  $\text{H}_2\text{SO}_4$  at 100° into a ketone,  $\text{C}_{14}\text{H}_{16}\text{O}$ , m.p. 95—96° (oxime, m.p. 175—177°), which is probably stereoisomeric with (VIII) (below)]. The bromide from (IV) and  $\text{PBr}_3$  in  $\text{CCl}_4$  with  $\text{CHK}(\text{CO}_2\text{Et})_2$  in  $\text{C}_6\text{H}_6$  gives (after hydrolysis and decarboxylation) a stereoisomeric (?) 2-phenylcyclohexylacetic acid, m.p. 84—85° (cf. Ghose, A., 1935, 1495). The chloride of (VII) with  $\text{AlCl}_3$  in  $\text{CS}_2$  at 0° gives 9-keto-1:2:3:4:9:10:11:12-octahydrophenanthrene (hexahydrophenanthrene) (VIII), b.p. 137—138°/0.5 mm. (oxime, m.p. 123.5—124.5°; semicarbazone, m.p. 195—196°), also formed from (VII) and conc.  $\text{H}_2\text{SO}_4$  at 100°. Reduction ( $\text{H}_2$ ,  $\text{PtO}_2$ , EtOH) of (VIII) affords the 9-hydroxyoctahydrophen-

anthrene, m.p. 114—115°, dehydrogenated (Pt-black at 310—320°) to 9-phenanthrol and dehydrated ( $\text{ZnCl}_2$  at 180°) to hexahydrophenanthrene, b.p. 125—126°/2.5 mm., which is similarly dehydrogenated to phenanthrene. *as*-Octahydrophenanthrene (A., 1933, 1042) is oxidised ( $\text{CrO}_3$ , AcOH) to a mixture of (VIII) and an isomeride (?) (oxime, m.p. 186.5—187.5°). The Grignard reagent from impure 1-chloro-2-benzylcyclohexane, b.p. 85—100°/0.2 mm. [from (III) and  $\text{SOCl}_2$  in  $\text{NPhMe}_3$ ], and  $\text{CO}_2$  give *cis*- (IX), m.p. 86—88°, and *trans*- (X), m.p. 133—134°, -2-benzylhexahydrobenzoic acids. The Grignard reagent from 1-bromo-2-benzylcyclohexane, b.p. 120°/0.4 mm. [from (III) and  $\text{PBr}_3$  in cold  $\text{CCl}_4$ ], with  $\text{ClCO}_2\text{Et}$  affords (after hydrolysis with aq. EtOH-KOH) (X), probably 4-benzylhexahydrobenzoic acid, m.p. 140—141° (the formation of which involves a migration), and 2:2'-dibenzyl-dicyclohexyl, m.p. 180—181° (cloudy; clear at 191°).  $o\text{-CH}_2\text{Ph}\cdot\text{C}_6\text{H}_4\cdot\text{CO}_2\text{H}$  is reduced by Na and amyl alcohol to (X) and by  $\text{H}_2$  and  $\text{PtO}_2$  in AcOH to *o*-hexahydrobenzylbenzoic acid, m.p. 95.5—96.5° [oxidised (alkaline  $\text{KMnO}_4$ ) to  $o\text{-C}_6\text{H}_4(\text{CO}_2\text{H})_2$ ]. (X) with cold conc.  $\text{H}_2\text{SO}_4$ , or its chloride with  $\text{AlCl}_3$  in cold  $\text{CS}_2$ , leads to *trans*-hexahydroanthrone (XI), m.p. 109—109.5° (oxime, m.p. 174.5—175.5°); (IX) similarly gives *cis*-hexahydroanthrone (XII), m.p. 79—80° (cloudy; clear at 85°) (oxime, m.p. 150—151°), and some (XI). Dehydrogenation (Pt-black at 300°) of (XI) and (XII) affords anthracene. A mixture of (XI) and (XII) is formed from either (IX) or (X) and conc.  $\text{H}_2\text{SO}_4$  at 100°; interconversion of the ketones probably occurs through an intermediate enolic form.

[By R. ROBINSON.] Contrary to the previous statement (A., 1934, 75), cyclohexene oxide and  $\text{CH}_2\text{Ph}\cdot\text{CH}_2\cdot\text{MgBr}$  (XIII) give cyclopentyl- $\beta$ -phenylethylcarbinol (XIV), also prepared from (XIII) and cyclopentylformaldehyde. The following corrections should be made in the abstract: the chloride and *p*-nitrobenzoate of 2- $\beta$ -phenylethylcyclohexanol are those of (XIV); the 2- $\beta$ -phenylethylcyclohexanone is cyclopentyl  $\beta$ -phenylethyl ketone; 2- $\beta$ -phenylethyl-1-ethylcyclohexanol is cyclopentyl- $\beta$ -phenylethylethylcarbinol; 1:2:3:4:9:10:11:12-octahydrophenanthrene is 1-cyclopentylhydrindene; 2- $\beta$ -phenylethyl-1-ethyl- $\Delta^1$ -cyclohexene and ethyloctahydrophenanthrene are best described as hydrocarbons, both  $\text{C}_{16}\text{H}_{22}$ . The apparent difference between the previous results and those of Bardhan and Sen-Gupta (A., 1932, 1241) no longer exists. H. B.

**Preparation of 9:10-dihydrophenanthrene and its derivatives.** A. BURGER and E. MOSETTIG (J. Amer. Chem. Soc., 1935, 57, 2731—2732).—Reduction of phenanthrene with  $\text{H}_2$  at 2000—4000 lb. per sq. in. at 220° in presence of a Cu—Cr—BaO catalyst (Connor *et al.*, A., 1932, 477) gives 60—80% of the 9:10- $\text{H}_2$ -derivative, m.p. 31—32°, which with AcCl in  $\text{CS}_2$  or  $\text{PhNO}_2$  affords 2-acetyl-9:10-dihydrophenanthrene (I), m.p. 51—52° (oxime, m.p. 146—147.5°; semicarbazone, m.p. 236—237°). (I) is oxidised by  $\text{CrO}_3$  to 2-acetyl-9:10-phenanthraquinone, m.p. 223—224°, and by NaOCl to 9:10-dihydrophenanthrene-2-carboxylic acid, m.p. 211.5—212.5° [*Me* ester, an oil, dehydrogenated (Se at 300°) to phenanthrene-2-carboxylic acid].

2-Bromoacetyl-9:10-dihydrophenanthrene has m.p. 93.5—95°. 9:10-Dihydroanthracene is obtained in nearly quant. yield by reduction ( $H_2$ ; Cu chromite; 160°) of anthracene. H. B.

Higher benzenoid hydrocarbons. II. Isomeric bromofluorenones. III. Isomeric bromo-9-fluorenols and bromofluorenes. H. F. MILLER and G. B. BACHMAN (J. Amer. Chem. Soc., 1935, 57, 2443—2446, 2447—2450).—II. The chloride, m.p. 162—163°, of 4-bromobenzophenone-2'-carboxylic acid (I) is converted by liquid  $NH_3$  into the amide, m.p. 184.5—185°, and thence by alkaline NaOBr into 4-bromo-2'-aminobenzophenone (II), m.p. 108°, also prepared by hydrolysis (90%  $H_2SO_4$ , AcOH) of the reaction product from 2-*p*-toluenesulphonamidobenzoyl chloride, PhBr, and  $AlCl_3$ , and from (I) and  $N_3H$  (method: Oesterlin, A., 1932, 1030). When the diazo-solution from (II) is warmed, 3-bromofluorenene, m.p. 162°, is obtained. The chloride, m.p. 119—120°, of 3-bromobenzophenone-2-carboxylic acid with  $NH_4HCO_3$  affords the amide, m.p. 135—140°, converted (NaOBr) into 3-bromo-2-aminobenzophenone, m.p. 128—130°, and thence (as above) into 4-bromofluorenene, m.p. 190—191°, which is also prepared from 2-bromodiphenyl-2'-carboxylic acid, m.p. 186—187° (from  $o$ - $C_6H_4$ - $CO_2Me$ ,  $o$ - $C_6H_4Br$ , and Cu at 260—290°), and conc.  $H_2SO_4$  at 100° (bath).

III. Bromofluorenones (A) are reduced (Zn dust, conc. aq.  $NH_3$ , EtOH) to bromofluorenols (B), which are reduced further to bromofluorenes [also prepared by Clemmensen reduction of (A)] by red P and I in AcOH. (B) with HBr and HCl in EtOH give the dihalogenofluorenes. The following are new: 3-, m.p. 142—145°, and 4-, m.p. 149—150°, -bromo-9-fluorenols; 3- (III), m.p. 90—91°, and 4- (IV), m.p. 165°, -bromofluorenes; 2:9-, m.p. 107.5—108.5°, 3:9-, m.p. 124—125°, and 4:9-, m.p. 194—195°, -dibromofluorenes; 9-chloro-3-, m.p. 116—117°, and 4-, m.p. 141—142°, -bromofluorenes. Fluorene and  $Hg(OAc)_2$  give (mainly) the 4-OAc-Hg-derivative [converted by successive treatment with  $CaCl_2$  and Br into (IV)]; in the absence of solvent some of the 3-derivative [converted into (III)] is also formed. In the latter case, the intermediate mixture of  $CHg$ -derivatives differs considerably from the product obtained by Goswami and Das-Gupta (A., 1931, 1435).

$\omega$ -Benzyl derivatives of acetophenone and their reduction products. G. A. HILL and A. J. COFRANCESCO (J. Amer. Chem. Soc., 1935, 57, 2426—2428).—In  $\alpha$ -diphenylisopropyl ketone (I) (oxime, m.p. 157°), formed together with  $COPh \cdot CH_2 \cdot CH_2Ph$  (II) from  $COPhMe$ ,  $CH_2PhCl$ , and  $NaNH_2$  in xylene, is reduced (Na, EtOH) to  $\alpha$ -diphenyl- $\beta$ -benzylpropyl alcohol (phenylcarbamate, m.p. 185°). (II) is benzylated (above method) to Ph  $\beta$ -phenyl- $\alpha$ -dibenzylethyl ketone (tribenzylacetophenone) (III), m.p. 111—128°, which is reduced by Na and EtOH to  $\alpha$ -diphenyl- $\beta$ -dibenzylpropyl alcohol, decomp. when heated at low pressure, and by red P and 47% HI to  $C(CH_2Ph)_4$  (yield 13%). (I)—(III) could not be reduced by Clemmensen's method. H. B.

Structure of metallic derivatives formed by adding Grignard reagents to unsaturated ket-

ones. E. P. KOHLER, M. TISHLER, and H. POTTER (J. Amer. Chem. Soc., 1935, 57, 2517—2521).—The compound,  $[CHPh_2 \cdot CH \cdot CO \cdot C_6H_2Me_3]MgBr$  (A), obtained from mesityl styryl ketone (I) and  $MgPhBr$ , with  $BzCl$  gives  $\approx 96\%$  of  $\gamma$ -diphenyl- $\alpha$ -mesityl- $\Delta^a$ -propenyl benzoate (II), m.p. 162°. Mesityl  $\beta$ -diphenylethyl (III) or  $\alpha$ -bromo- $\beta$ -diphenylethyl ketones and  $MgEtBr$  afford an isomeride (B) of (A); a geometrical isomeride (IV), m.p. 148°, of (II) is obtained from (B) and  $BzCl$ . (II) and (IV) are both hydrolysed (EtOH-NaOH) to (III). Ability to combine with  $RCHO$  is no indication of the structure of such Mg derivatives. Thus, (B) and  $PhCHO$  afford  $\beta$ -trimethylbenzoyl- $\alpha$ - $\gamma$ -triphenylpropyl alcohol, m.p. 132°, oxidised ( $CrO_3$ , AcOH) to  $\alpha$ -benzoyl- $\alpha$ -trimethylbenzoyl- $\beta$ -diphenylethane (V), m.p. 107°, and polymeric material. Acidification of a solution of (V) in  $MeOH$ -NaOH gives an enol, m.p. 137°, which reverts to (V) in presence of org. bases; the relative stability of the enol is due to the  $C_6H_2Me_3$  group since the enol of  $CHBz_2 \cdot CHPh$ , is mobile. The Mg derivative from  $CHPh_2 \cdot CH_2 \cdot COPh + MgEtBr$  with  $C_6H_2Me_3 \cdot COCl$  affords (V) and  $\alpha$ - $\gamma$ -triphenyl- $\Delta^a$ -propenyl trimethylbenzoate, m.p. 93°. The product from (I) +  $MgMeI$  treated with  $BzCl$  gives (after removal of ester with cold  $MeOH$ -NaOH) a little of the enol, m.p. 128°, of  $\alpha$ -benzoyl- $\alpha$ -trimethylbenzoyl- $\beta$ -phenylpropane, m.p. 130°; this enol has the same stability as that of (V). Reduction (Adams) of (I) affords mesityl  $\beta$ -phenylethyl ketone, b.p. 191—192°/about 5 mm.; successive treatment of this with  $MgEtBr$ ,  $BzCl$ , and  $MeOH$ -NaOH gives 12% of  $\alpha$ -benzoyl- $\alpha$ -trimethylbenzoyl- $\beta$ -phenylethane (VI), m.p. 118°, fresh solutions ( $MeOH$ ) of which contain 4% of enol (equilibration with piperidine gives approx. equal amounts of keto- and enol forms). (VI) is also prepared from  $CH_2PhCl$  and the Na derivative of  $CH_2Bz \cdot CO \cdot C_6H_2Me_3$  (VII), and by catalytic reduction of  $\alpha$ -benzoyl- $\alpha$ -trimethylbenzoyl- $\beta$ -phenylethylene, obtained in poor yield (method: Knoevenagel and Erler, A., 1903, i, 636) from (VII) and  $PhCHO$ .  $\alpha$ -Diphenyl- $\gamma$ -mesityl- $\Delta^a$ -propenyl benzoate (?), m.p. 110°, is formed from Ph trimethylstyryl ketone +  $MgPhBr$  and  $BzCl$ . Decomp. of (A) with cold dil. HCl and treatment of the product (in moist light petroleum) with  $O_2$  gives the peroxide, m.p. 116—117° (decomp.), of  $\gamma$ -diphenyl- $\alpha$ -mesityl- $\Delta^a$ -propen- $\alpha$ -ol [*i.e.*, the enolic form of (III), stabilised by the  $C_6H_2Me_3$  group]. H. B.

Preparation of benzanthrone compounds and benzanthronecarboxylic acids.—See B., 1936, 92.

Additions to conjugated systems in anthracene series. III. Factors influencing mode and extent of reaction of Grignard reagent with ketones. P. L. JULIAN, W. COLE, and T. F. WOOD (J. Amer. Chem. Soc., 1935, 57, 2508—2513).—10-Benzylideneanthrone and  $MgMeI$  give (by 1:2-addition) 10-benzylidene-9-methyl-9:10-dihydroanthranol, m.p. 148°, converted by Br in  $CHCl_3$  into 10- $\alpha$ -bromobenzyl-9-bromomethylanthracene (I), m.p. 168 (decomp.), which with  $NaOAc$ -AcOH affords 10- $\alpha$ -acetoxybenzyl-9-acetoxymethylanthracene, m.p. 188; treatment of the initial reaction product (in solution) with  $O_2$  gives a small amount of a peroxide, decomp. 74° [to anthraquinone (II)]. (I) and Br in  $CHCl_3$

afford  $\text{CH}_2\text{PhBr}$  and 10-bromo-9-bromomethylanthracene. The formation of (II) and  $\text{MeCHO}$  from 10-hydroxy-10-ethylanthrone (III), m.p.  $107^\circ$  [from (II) and  $\text{MgEtBr}$  in  $\text{Et}_2\text{O}-\text{C}_6\text{H}_6$ ], and  $\text{AcOH-conc. H}_2\text{SO}_4$  in  $\text{O}_2$  supports the view that 10-ethylideneanthrone (IV), b.p.  $245-247^\circ/20$  mm. [obtained when (III) is distilled at atm. pressure in  $\text{N}_2$ ], reacts as 9-hydroxy-10-vinylanthracene. The ready oxidation ( $\text{O}_2$ ) of (IV) to (II) and vinyl alcohol through the peroxide, and the oxidative decomp. of (IV) to (II) and  $\text{C}_2\text{H}_2$  during attempted distillation at atm. pressure, are thus satisfactorily explained. Anthraphenone, which resembles an  $\alpha\beta$ -unsaturated ketone, is reduced by  $\text{MgPhBr}$  to 10 : 10'-dibenzoyl-9 : 10 : 9' : 10'-tetrahydro-9 : 9'-dianthryl; no reaction occurs with  $\text{MgMeI}$ . 9 : 10-Dihydroanthraphenone similarly affords 9- $\alpha$ -hydroxybenzhydryl-9 : 10-dihydroanthracene, m.p.  $173^\circ$ , dehydrated ( $\text{AcOH-conc. H}_2\text{SO}_4$ ) to 9-benzhydrylidene-9 : 10-dihydroanthracene, m.p.  $258^\circ$ , which is oxidised ( $\text{CrO}_3$ ,  $\text{AcOH}$ ) to  $\text{COPh}_2$  and (II). Pure products could not be isolated from 9-benzoyl-10-phenylanthracene (V); the 9 : 10- $\text{H}_2$ -derivative of (V) similarly gives (V), presumably owing to oxidation of the intermediate  $\text{Mg}$  compound. H. B.

**Action of glycerol and sulphuric acid on pyrene: history of benzanthrone.** R. SCHOLL and H. K. MEYER (Ber., 1936, 69, [B], 152-158).—Pyrene is converted by  $\text{H}_2\text{SO}_4$  and glycerol at  $100-110^\circ$  into 1 : 9 : 8-diperinaphth-2 : 9-anthra-2-one (I), m.p.  $243^\circ$  after darkening, which is not further affected by the reactants at  $140^\circ$  and is not transformed into pyranthrone-like substances by  $\text{NaCl-AlCl}_3$  and  $\text{BzCl}$ . (I) readily gives a

(?)  $\text{-Br}_2$ -derivative and is converted by boiling  $\text{HNO}_3$  ( $d$  1.42) into a ( $\text{NO}_2$ )<sub>2</sub>-derivative, m.p.  $>330^\circ$ , whence the ( $\text{NH}_2$ )<sub>2</sub>- and ( $\text{NHAc}$ )<sub>2</sub>-compounds. When treated with red P and boiling HI ( $d$  1.7), (I) is transformed into 1 : 9 : 8-diperinaphth-2 : 3 : 4 : 9-tetrahydroanthracene, m.p.  $107-108^\circ$  (picrate), re-oxidised to (I) by  $\text{H}_2\text{SO}_4$  and glycerol and converted by passage over heated Cu into 1 : 9 : 8-diperinaphth-2 : 9-dihydroanthracene. (I) is oxidised by  $\text{CrO}_3$  in boiling  $\text{AcOH}$  to the quinone,  $\text{C}_{19}\text{H}_8\text{O}_2$ , m.p.  $>330^\circ$  after darkening at  $300^\circ$ . The history of the discovery of benzanthrone is given (cf. A., 1929, 1305). H. W.

**cis- and trans-1 : 3-Diketodecahydronaphthalene.** C. K. CHUANG and Y. L. TIEN (Ber., 1936, 69, [B], 31).—Condensation of cyclohexenyl Me ketone with  $\text{CHNa}(\text{CO}_2\text{Et})_2$  by a slight modification of the method of Kon *et al.* (A., 1927, 150) affords Et 1 : 3-diketodecahydronaphthalene-4-carboxylate (I), m.p.  $114^\circ$  (semicarbazone, m.p.  $229^\circ$ ), in 87% yield. It is hydrolysed by boiling 20%  $\text{KOH-EtOH}$  to trans-1 : 3-diketodecahydronaphthalene (II), m.p.  $152-153^\circ$  (lit. m.p.  $142^\circ$ ) [dioxime, m.p.  $207^\circ$  (decomp.); disemicarbazone, m.p.  $241^\circ$  (decomp.); trans-1 : 3-diketo-2-benzylidenedecahydronaphthalene, m.p.  $229^\circ$ ; methylenedi-trans-1 : 3-diketodecahydronaphthalene, m.p.  $172-173^\circ$ ]. The configuration of (II) follows from its oxidation by  $\text{NaOBr}$  to trans-o-carboxycyclohexaneacetic acid and by  $\text{KMnO}_4$  to trans-cyclohexane-

1 : 2-dicarboxylic acid. Treatment of (I) with dil.  $\text{KOH-EtOH}$  at  $15-20^\circ$  gives the corresponding acid, which passes with loss of  $\text{CO}_2$  into cis-1 : 3-diketodecahydronaphthalene (III), m.p.  $124-125^\circ$  (dioxime, m.p.  $152-153^\circ$ ; methylenedi-cis-1 : 3-diketodecahydronaphthalene, m.p.  $147-148^\circ$ ). Oxidation of (III) with  $\text{NaOBr}$  leads to cis-o-carboxycyclohexaneacetic acid, m.p.  $146^\circ$ . (III) is isomerised to (II) by treatment with boiling 20%  $\text{KOH-EtOH}$ . Hydrolysis of (I) with boiling 15%  $\text{HCl}$  (cf. Ruzicka *et al.*, A., 1931, 1302) followed by distillation of the product in vac. gives an acid,  $\text{o-C}_6\text{H}_{10}\text{Ac}\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$  or  $\text{o-CH}_2\text{Ac}\cdot\text{C}_6\text{H}_{10}\cdot\text{CO}_2\text{H}$ , m.p.  $52-53^\circ$  (Ag salt; semicarbazone, m.p.  $158-160^\circ$ ); the corresponding crude Et ester is converted by  $\text{NaOEt}$  in  $\text{Et}_2\text{O}$  into (II). H. W.

**Preparation of diaryl  $\alpha$ -diketones.** H. H. HATT, A. PILGRIM, and W. J. HURRAN (J.C.S., 1936, 93-96).— $\text{COAr}\cdot\text{CH}_2\text{Ph}$  (1 mol.) are oxidised by  $\text{SeO}_2$  (1.5 mols.) in  $\text{Ac}_2\text{O}$  at  $140-150^\circ$  to  $\text{COAr}\cdot\text{COPh}$  (I) in almost quant. yields; the following are prepared: benzil; 4-phenyl-, m.p.  $104-105^\circ$ ; 4-chloro-, m.p.  $73^\circ$ , 4-bromo-, m.p.  $86.5^\circ$ , and 4-methyl- (II), m.p.  $31^\circ$ , -benzils; 2 : 4-, b.p.  $228^\circ/16$  mm., 2 : 5-, m.p.  $41^\circ$ , and 3 : 4-, m.p.  $63.5^\circ$ , -dimethylbenzils, oxidised ( $\text{H}_2\text{O}_2$ ,  $\text{N-NaOH}$ ,  $\text{C}_6\text{H}_5\text{N}$ ) to  $\text{BzOH}$  and 2 : 4-, 2 : 5-, and 3 : 4- $\text{C}_6\text{H}_3\text{Me}_2\cdot\text{CO}_2\text{H}$ , respectively; 2 : 4 : 6-trimethylbenzil, m.p.  $136-137^\circ$ . (I) and  $\text{CO}(\text{NH}_2)_2$  in  $\text{EtOH-KOH}$  give 5-phenyl-5-arylhydantoin and varying amounts of phenylarylacetylenediureide,

$\text{CO} < \begin{array}{c} \text{NH}\cdot\text{CPh}\cdot\text{NH} \\ \text{NH}\cdot\text{CAr}\cdot\text{NH} \end{array} > \text{CO}$ . The following are described: 5-phenyl-5-p-diphenyl-, m.p.  $242-242.5^\circ$ , -5-p-chlorophenyl-, m.p.  $243^\circ$ , -5-p-bromophenyl-, m.p.  $239^\circ$ , -5-o-4'-xylyl-, m.p.  $225^\circ$ , -5-m-4'-xylyl-, m.p.  $269^\circ$ , -5-p-xylyl-, m.p.  $226^\circ$ , and -5-p-tolyl-hydantoin; phenyl-p-diphenyl-, m.p.  $316-318^\circ$ , -p-chlorophenyl-, m.p.  $339^\circ$ , -o-4'-xylyl-, m.p.  $333^\circ$ , and d-p-tolyl-, m.p.  $335^\circ$ , -acetylenediureides. The compound (m.p.  $99-101^\circ$ ) described as (II) by Weiss (A., 1920, i, 555) is impure p- $\text{C}_6\text{H}_4\text{Me}\cdot\text{CO}\cdot\text{CH}_2\text{Ph}$ , m.p.  $110-111^\circ$ , now shown to be formed [together with (II)] by hydrolysis ( $\text{EtOH}$ ) of p- $\text{C}_6\text{H}_4\text{Me}\cdot\text{CO}\cdot\text{CPhBr}_2$  (*loc. cit.*). (II) undergoes the benzilic acid change (cf. *loc. cit.*) yielding phenyl-p-tolylglycolic acid, m.p.  $132^\circ$ . Hydrolysis ( $\text{MeOH-NaOMe}$ ) of p- $\text{C}_6\text{H}_4\text{Me}\cdot\text{CO}\cdot\text{CHPhBr}$ , m.p.  $87.5-88^\circ$  (from p- $\text{C}_6\text{H}_4\text{Me}\cdot\text{CO}\cdot\text{CH}_2\text{Ph}$  and Br in boiling  $\text{CHCl}_3$ ), gives r-p-toluoylphenylcarbinol, m.p.  $110-111^\circ$ ; this prep. is more convenient than those of McKenzie *et al.* (J.C.S., 1914, 105, 1583) and Weissberger *et al.* (A., 1930, 475). H. B.

**Constitution of campnospermonol.** T. G. H. JONES (Proc. Roy. Soc. Queensland, 1934, 45, 38-40).—Campnospermonol (I) is  $\text{C}_{25}\text{H}_{40}\text{O}_2$  and not  $\text{C}_2\text{H}_{42}\text{O}_2$  or  $\text{C}_{28}\text{H}_{44}\text{O}_2$  (Jones and Smith, A., 1928, 291); the structure  $\text{m-OH}\cdot\text{C}_6\text{H}_4\cdot\text{CH}_2\cdot\text{CO}\cdot[\text{CH}_2]_7\cdot\text{CH}\cdot\text{CH}\cdot[\text{CH}_2]_7\cdot\text{Me}$  is assigned to (I). Decomp. of oximinohydrocampnospermonyl Me ether (II) with  $\text{PCl}_5$  yields m- $\text{OMe}\cdot\text{C}_6\text{H}_4\cdot\text{CN}$  (III) and stearic acid; similarly oximinocampnospermonyl Me ether (IV) yields (III) and oleic acid. Oxidation of (IV) yields suberic, azelaic, nonoic, and m-methoxybenzoic acids. The fatty acid previously isolated by oxidation of (II) is

shown to be a mixture of margaric and stearic acids.

CH. ABS. (r)

**Hydroxypolyketones. II. Dibenzoylcarbinol.** A. H. BLATT and W. L. HAWKINS (J. Amer. Chem. Soc., 1936, 58, 81—84).—Dibenzoylcarbinyl acetate (I), solutions of which in 95% EtOH at room temp. contain 5.1% enol (indirect Br titration), is hydrolysed (a) by aq.  $\text{Na}_2\text{CO}_3$  to AcOH, BzOH, and  $\text{CH}_2\text{Bz}\cdot\text{OH}$ , (b) by aq. 5% NaOH to AcOH and BzOH, (c) by aq.  $\text{NaHCO}_3$  in MeOH (EtOH) to AcOH,  $\text{CH}_2\text{Bz}\cdot\text{OH}$ , and MeOBz (EtOBz), (d) by short treatment with cold  $\text{H}_2\text{SO}_4$  to dibenzoylcarbinol (II), m.p. 111—112° (yield 25%) (Bigelow *et al.*, A., 1935, 346). Alkalis and (II) give the same products as (I). (II) is acetylated to (I), is oxidised [ $\text{Cu}(\text{OAc})_2$  in 60% AcOH] to benzil, and when distilled at 4 mm. rearranges to  $\text{CH}_2\text{Bz}\cdot\text{OBz}$ . (II) is not oxidised by I in neutral or acid solution, indicating the non-formation of  $\text{OH}\cdot\text{CPh}\cdot\text{CBz}\cdot\text{OH}$  under these conditions. (II) does not give colours with  $\text{NH}_2$ -acids.

H. B.

**Chalkones and chalkone oxides. I. Phenyl 3:4-methylenedioxy-styryl ketone.** R. P. DODWADMATH and T. S. WHEELER (Proc. Indian Acad. Sci., 1935, 2, A, 438—451).—A comparative study of the reactivities of Ph 3:4-methylenedioxy-styryl ketone (I) and of Ph 6-nitro-3:4-methylenedioxy-styryl ketone (II). With Br (1 mol.) (I) yields Ph  $\alpha\beta$ -dibromo- $\beta$ -3:4-methylenedioxyphenylethyl ketone (A., 1922, i, 1035), which with EtOH and MeOH gives respectively Ph  $\alpha$ -bromo- $\beta$ -ethoxy-, m.p. 143—144°, and  $\beta$ -methoxy-, m.p. 115—116°,  $\beta$ -3:4-methylenedioxyphenylethyl ketone. With Br (2 mols.) (I) gives Ph  $\alpha\beta$ -dibromo- $\beta$ -6-bromo-3:4-methylenedioxyphenylethyl ketone, m.p. 174—175°, which yields  $\alpha$ -bromo- $\beta$ -ethoxy-, m.p. 126—127°, and  $\alpha$ -bromo- $\beta$ -methoxy-, m.p. 131—132°, compounds as above, and which with KI in  $\text{COMe}_2$  forms Ph 6-bromo-3:4-methylenedioxy-styryl ketone, m.p. 146—147°, which is synthesised from 6-bromopiperonal and COPhMe. Treatment of (I) in AcOH with  $\text{Cl}_2$  gives first a product converted by recrystallisation from EtOH into Ph  $\alpha$ -chloro- $\beta$ -ethoxy- $\beta$ -3:4-methylenedioxyphenylethyl ketone, m.p. 118—119°; on longer treatment, Ph  $\alpha\beta$ -dichloro- $\beta$ -6-chloro-3:4-methylenedioxyphenylethyl ketone, m.p. 127—128°, is formed. With KCN-EtOH, (III) forms  $\beta$ -benzoyl- $\alpha$ -3:4-methylenedioxyphenylpropionitrile, m.p. 132—133°, hydrolysed to the acid, m.p. 143—144°. The structure of (III) and of these derivatives is confirmed by the similar formation of  $\beta$ -benzoyl- $\alpha$ -phenylpropionitrile from Ph  $\alpha\beta$ -dibromo- $\beta$ -phenylethyl ketone. With Br (1 mol.), (II) yields Ph  $\alpha\beta$ -dibromo- $\beta$ -6-nitro-3:4-methylenedioxyphenylethyl ketone, m.p. 174—175°; this does not react with EtOH or further with Br; with KI it regenerates (II). With  $\text{Cl}_2$ , (II) gives the corresponding  $\alpha\beta$ -dichloro-compound, m.p. 151—152°. (I) with NaOEt and  $\text{CH}_3\text{Ac}\cdot\text{CO}_2\text{Et}$  in EtOH yields Et 4-phenyl-2-(3':4'-methylenedioxyphenyl)- $\Delta^6$ -cyclohexen-6-one-1-carboxylate, m.p. 151—152°; (II) does not react. (I) is catalytically reduced (Pd) to  $\alpha$ -phenyl- $\gamma$ -3:4-methylenedioxyphenylpropyl alcohol, m.p. 95—96°, without formation of the saturated ketone; (II) is not reduced. With  $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$ , (I) forms 3-phenyl-5-(3':4'-methylenedioxyphenyl)pyrazoline (?), decomp. on drying

(hydrochloride, m.p. 197—198°; picrate, m.p. 185—186°; Ac derivative, m.p. 153—154°); this substance does not give Knorr's pyrazoline reaction, but its formation of a hydrochloride, and failure to give  $\text{NH}_3$  when reduced by Na-Hg, are against its being a hydrazone. With  $\text{NHPh}\cdot\text{NH}_2$ , (I) forms 1:3-diphenyl-5-(3':4'-methylenedioxyphenyl)pyrazoline, m.p. 129—130° (pyrazoline reaction; NO-derivative).

Action of  $\text{H}_2\text{O}_2$  (6%) on (I) in MeOH and  $\text{COMe}_2$  yields Ph 3:4-methylenedioxyphenylstyryl ketone oxide (IV), m.p. 99—100°; with  $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$  this forms a hydrazone, m.p. 173—174° (regarded as such and not as a pyrazoline, since it does not form a NO-derivative), which with NaOEt or  $\text{Ac}_2\text{O}$  condenses to 3-phenyl-5-(3':4'-methylenedioxyphenyl)pyrazole, m.p. 194—195°. With MeOH or EtOH and  $\text{H}_2\text{SO}_4$ , the O-ring opens, and Ph  $\alpha$ -hydroxy- $\beta$ -methoxy- (V), m.p. 117—118°, and Ph  $\alpha$ -hydroxy- $\beta$ -ethoxy- $\beta$ -3:4-methylenedioxyphenylethyl ketone, m.p. 93—94°, respectively, are obtained. When (V) is heated with NaOAc-AcOH or with aq. NaOH, or (IV) boiled (30 sec.) with aq. NaOH-EtOH, Ph 3:4-methylenedioxybenzyl diketone, m.p. 114—115°, is formed, which with  $o\text{-C}_6\text{H}_4(\text{NH}_2)_2$  yields 2-phenyl-3-(3':4'-methylenedioxybenzyl)quinoxaline, m.p. 137—138°. If (IV) is boiled with aq. NaOH-EtOH for 4 hr.,  $\alpha$ -phenyl- $\beta$ -3:4-methylenedioxyphenyl- $\alpha$ -lactic acid, m.p. 149—150°, is produced, oxidised ( $\text{K}_2\text{Cr}_2\text{O}_7\text{-AcOH}$ ) to Ph 3:4-methylenedioxybenzyl ketone (A., 1930, 1041). (II) is oxidised by  $\text{H}_2\text{O}_2$  (6%) in  $\text{COMe}_2$  to Ph 6-nitro-3:4-methylenedioxy-styryl ketone oxide (VI), m.p. 159—160°, but this is not readily isolated, and is better prepared by adding NaOEt to  $\text{CH}_2\text{Br}\cdot\text{COPh}$  and 6-nitropiperonal in EtOH at 0°. (VI) does not react with EtOH or MeOH, or with NaOH, but with HCl in AcOH gives Ph  $\beta$ -chloro- $\alpha$ -hydroxy- $\beta$ -6-nitro-3:4-methylenedioxyphenylethyl ketone, m.p. 183—184°. Action of  $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$  on (II) in AcOH gives Ph 6-nitro-3:4-methylenedioxy-styryl ketone-N-acetylhydrazone, m.p. 244—245°; with  $\text{NHPh}\cdot\text{NH}_2$ , the  $\beta$ -phenylhydrazone, m.p. 159—160°, is formed, which is condensed (AcOH) to 1:3-diphenyl-5-(6'-nitro-3'-4'-methylenedioxyphenyl)pyrazoline, m.p. 203—204°, from which  $\text{AgNO}_3$  forms the corresponding  $\beta$ -pyrazole, m.p. 163—164°, also obtained from (VI) and  $\text{NHPh}\cdot\text{NH}_2$ . Results show that the 6- $\text{NO}_2$  removes the enhanced reactivity which  $\text{CH}_2\text{O}_2$  confers on one of the Br of the chalkone dibromide, and reduces the reactivity of the oxide towards EtOH or MeOH, but not towards HCl.

E. W. W.

**Synthesis of 2:6-dihydroxy-4-methoxyphenyl  $\beta$ -phenylethyl ketone** obtained from the oil of *Ponulus balsamifera*, L. A. GORIS and H. CANAL (Compt. rend., 1935, 201, 1520—1521).—2:4:6-Trihydroxyphenyl  $\beta$ -phenylethyl ketone (cf. A., 1926, 1135) with  $\text{Me}_2\text{SO}_4$  affords 2:6-dihydroxy-4-methoxyphenyl  $\beta$ -phenylethyl ketone, m.p. 168°, identical with the natural product.

J. L. D.

**Organic salts of a diaminobenzoquinonedisulphonic acid.** (MILLE.) Y. GARREAU (Compt. rend., 1935, 201, 1515—1517; cf. A., 1935, 338).—Diaminobenzoquinonedisulphonates of the following bases are prepared from the  $\text{NH}_4$  salt and the base

in dil. HCl: glycine (+2H<sub>2</sub>O, decomp. about 240°), creatine [+2H<sub>2</sub>O, 245—248° (decomp.)], adenine (+4H<sub>2</sub>O, which at 105—110° is converted into +1H<sub>2</sub>O), aliphatic NH<sub>2</sub>-acids, uric acid and guanidine bases, and many alkaloids. J. L. D.

**Anthragallol esters.** M. TANAKA (J. Chem. Soc. Japan, 1935, 55, 196—197).—The methylation of anthragallol with Me<sub>2</sub>SO<sub>4</sub>-NaOH, and the 1:2:3-Me<sub>3</sub>, m.p. 173°; 2:3-Me<sub>2</sub>, m.p. 166°, and 3-Me, m.p. 143°, ethers, are described. CH. ABS. (r)

**Mechanism of the conversion of 2-aminoanthraquinone into indanthrone.** M. TANAKA (J. Chem. Soc. Japan, 1935, 56, 192—195).—Fusion of NH<sub>2</sub>Ph with alkali, in the presence of an oxidising agent or PhNO<sub>2</sub>, does not give phenazine or the *N*-oxide. Under similar conditions, 2-aminoanthraquinone (I) gives 2-amino-1-hydroxyanthraquinone (II) and dihydro-2'-amino-1:3'-dianthraquinonylamme (III). Alkali fusion of (II) gives, not indanthrone (IV), but a dihydrophenazinecarboxylic acid; (III), treated similarly, affords (IV). A mechanism is advanced for the formation of (IV) from (I), by way of (III). CH. ABS. (r)

**Manufacture of derivatives of chrysenequinones.**—See B., 1936, 139.

**Vat dyes of the benzanthrone series.** XV. **Synthesis of 5-methoxybenzanthrone and 5:5'-dimethoxyviolanthrone.** T. MAKI. XVI. **Constitution of dichlorinated violanthrone and preparation of some new Bz-3:3'-violanthrone derivatives.** T. MAKI and T. AOYAMA (J. Soc. Chem. Ind. Japan, 1935, 38, 630—636B, 636—642B; cf. this vol., 206).—XV. 1-Chloro-9-anthrone, m.p. 114° (corr.) (cf. B., 1923, 1216A) (obtained from 1-chloroanthraquinone and H<sub>2</sub>SO<sub>4</sub>-Al), when heated at 120° during 6 hr. with H<sub>2</sub>SO<sub>4</sub> and glycerol and the product boiled with 1% NaOH solution yields *o*-chlorobenzanthrone (I), m.p. 181.5°, and a compound, m.p. 121°, probably 4-chlorobenzanthrone. (I) is probably identical with  $\alpha$ -chlorobenzanthrone (B.P. 278.496; B., 1928, 9), and is oxidised by CrO<sub>3</sub>-H<sub>2</sub>O-AcOH to 5-chloroanthraquinone-1-carboxylic acid. (I) with KOH-MeOH at 150° for 7 hr. affords 5-methoxybenzanthrone (II), m.p. 191° (corr.). The OMe is very resistant to HI. (II) when heated at 210° with KOH-PhOH affords mainly 5:5'-dimethoxyviolanthrone (III), sol. in NaOH-Na<sub>2</sub>S<sub>2</sub>O<sub>4</sub>-EtOH-H<sub>2</sub>O, and about 35% of a compound (IV), sol. with difficulty in alcoholic alkaline Na<sub>2</sub>S<sub>2</sub>O<sub>4</sub> and considered to be similar to the *B* dyes described previously (cf. B., 1934, 752). (III) dyes cotton blue, fast to acids and alkalis. (IV) dyes cotton grey-blue. (I) when heated at 220° with KOH, or, better, KOH-PhOH, affords 5:5'-dihydroxyviolanthrone, almost insol. in the ordinary org. solvents and in alkaline Na<sub>2</sub>S<sub>2</sub>O<sub>4</sub>; addition of H<sub>2</sub>O to its solution in H<sub>2</sub>SO<sub>4</sub> gives a greenish-black ppt.

XVI. Careful chlorination of violanthrone in AcOH affords Bz-3:3'-dichloroviolanthrone (V) (cf. A., 1934, 754) and a little of a dark green vat dye, separated by means of PhNO<sub>2</sub>. (V) at 150° with KOH-MeOH affords Bz-3:3'-dimethoxyviolanthrone (cf. Jap. P. 109,582), which fairly readily forms a blue hyposulphite vat and dyes cotton fast indigo-blue.

The OMe groups are very resistant to HI. (V) when treated with H<sub>2</sub>SO<sub>4</sub>-MnO<sub>2</sub>-H<sub>3</sub>BO<sub>3</sub> at 60° during 1 hr. affords Bz-3:3'-dichloro-Bz-2:2'-dihydroxyviolanthrone, a violet-black cryst. powder, which dyes cotton from a blue Na<sub>2</sub>S<sub>2</sub>O<sub>4</sub> vat a dull green, similar to that obtained with Bz-2:2'-dihydroxyviolanthrone. (V) with NH<sub>3</sub>, H<sub>2</sub>O, and Cu at 200° for 7 hr. yields Bz-3:3'-diaminoviolanthrone, which dyes cotton from a blue Na<sub>2</sub>S<sub>2</sub>O<sub>4</sub> vat a dark violet-blue, almost unaffected by NaOCl. Similarly (V) when refluxed during 9 hr. with *p*-toluidine, anhyd. NaOAc, and Cu affords Bz-3:3'-di-*p*-toluidinoviolanthrone, a violet-black cryst. powder, which dyes cotton dark violet-blue from a blue vat. Reasons are given for the constitution assigned to (V).

H. G. M.

**Vat dyes of the benzanthrone series.** XVII. **Preparation and purification of dinitroviolanthrone.** XVIII. **Constitution of dinitroviolanthrone.** T. MAKI, Y. NAGAI, and Y. HAYASHI (J. Soc. Chem. Ind. Japan, 1935, 38, 710—715B, 715—720B).—XVII. The % of N in the product when violanthrone (I) is nitrated with HNO<sub>3</sub> (*d* 1.48)-AcOH increases with increase in the proportion of HNO<sub>3</sub>. Optimum conditions for the formation of the almost pure (NO<sub>2</sub>)<sub>2</sub>-derivative (II) are the nitration of 3 parts of (I) in 50 parts of AcOH with 30 parts of HNO<sub>3</sub> in 30 parts of AcOH at 60° for 12 hr. The small amount of by-product formed is removed either by crystallisation of (II) from C<sub>2</sub>H<sub>2</sub>Cl<sub>4</sub>, or by extraction with 80% H<sub>2</sub>SO<sub>4</sub> in which it is sol. When only 10 parts of HNO<sub>3</sub> at room temp. are used, a mixture of NO<sub>2</sub>- and (NO<sub>2</sub>)<sub>2</sub>-derivatives is formed. Nitration of (I) with HNO<sub>3</sub> (*d* 1.48)-H<sub>2</sub>SO<sub>4</sub> at 0—5° does not give (II), but a substance (III), probably a dinitrodihydroxyviolanthrone. The tinctorial properties of these derivatives are described.

XVIII. The following reactions prove that (II) is Bz-2-Bz-2'-dinitroviolanthrone (annexed formula). Reduction with Na<sub>2</sub>S<sub>2</sub>O<sub>4</sub>-NaOH affords the (NH<sub>2</sub>)<sub>2</sub>-derivative (IV), the green colour of which, on wool, is oxidised by 0.5% NaOCl to a black (V), which is reconverted into (IV) by Na<sub>2</sub>S<sub>2</sub>O<sub>4</sub>-NaOH. Oxidation of (IV) with CrO<sub>3</sub>-H<sub>2</sub>SO<sub>4</sub> affords first a substance, probably (VI), insol. NH<sub>3</sub>, and finally a substance,

NH<sub>3</sub>-sol., to which the structure (VII) is assigned. Oxidation of (II) with MnO<sub>2</sub>-H<sub>2</sub>SO<sub>4</sub>-H<sub>3</sub>BO<sub>3</sub> gives

its Bz-3-Bz-3'-(OH)<sub>2</sub>-derivative, which is not identical with the Bz-3-Bz-3'-dinitro-Bz-2-Bz-2'-dihydroxy-derivative obtained by nitration of the Bz-2-Bz-2'-(OH)<sub>2</sub>-compound (preceding abstract) with HNO<sub>3</sub> (d 1.48)-AcOH at 60°, but appears to be identical with (III). J. W. B.

**Carbamide derivatives in terpene series.** R. L. BATEMAN and A. R. DAY (J. Amer. Chem. Soc., 1935, 57, 2496—2498).—*l*-Menthylcarbamide, m.p. 140.2—140.6° (lit. 134—136°) [Ac, m.p. 118—119°, CH<sub>2</sub>Br·CO·, m.p. 111.8—112.3°, cinnamoyl, m.p. 144.3—145.1°, *p*-nitro-, m.p. 158.7—159.2°, and *p*-amino-benzoyl, m.p. 208—210° (decomp.), derivatives; additive compound, C<sub>10</sub>H<sub>19</sub>·NH·CO·NH·CH(OH)·CCl<sub>3</sub>, m.p. 146.2—147.2°, with chloral], *d*-bornylcarbamide, m.p. 165.7—166.3° [Ac, m.p. 129—129.5°, CH<sub>2</sub>Br·CO·, m.p. 136.1—136.5°, cinnamoyl, m.p. 220.2—220.8°, *p*-nitrobenzoyl, m.p. 230° (decomp.), and *p*-amino-benzoyl, m.p. 233° (decomp.), derivatives; additive compound, m.p. 180° (decomp.), with chloral], and 3-carbamido-2-ketocamphane (+0.5H<sub>2</sub>O), m.p. 177.8—178.4° (lit. 169°) (*p*-nitrobenzoyl derivative), are prepared from the appropriate RNH<sub>2</sub>·HCl and NO<sub>2</sub>·NH·CO·NH<sub>2</sub> in aq. NaHCO<sub>3</sub>. All m.p. are corr. Some of the above compounds possess narcotic activity. H. B.

**Anomalous mutarotation of salts of Reychler's acid.** IV. Comparison of 2-anilo-*d*-camphane-10-sulphonic acid with *d*-camphor-10-sulphonanilide. H. SUTHERLAND and R. L. SHRINER (J. Amer. Chem. Soc., 1936, 58, 62—63; cf. A., 1935, 1503).—The differences in properties of *d*-camphor-10-sulphonanilide, m.p. 120.5—121°, [α]<sub>D</sub><sup>25</sup> +76° in CHCl<sub>3</sub> (no mutarotation in 95% EtOH) [hydrolysed (25% HCl) with difficulty], and the dehydration product (I), [α]<sub>D</sub><sup>25</sup> −170.5° in CHCl<sub>3</sub>, of NH<sub>2</sub>Ph *d*-camphor-10-sulphonate support the view (A., 1935, 1118) that (I) is 2-anilo-*d*-camphane-10-sulphonic acid. H. B.

**Structure of methylsantene obtained by the catalytic dehydration of fenchyl alcohol by weak acids.** N. J. TOIVONEN, T. VEIJOLA, and S. FRIBERG (Suomen Kem., 1935, 8, B, 44—46).—Mild dehydration of fenchyl alcohol (cf. A., 1930, 348) gives, by intramolecular change, 1-methylsantene (A., 1935, 865), which with O<sub>3</sub> gives 1:3-diaceto-1-methylcyclopentane, b.p. 0.6/109°/6 mm. [semicarbazone, m.p. 230—232° (decomp.)]; this with NaOBr, followed by Zn-AcOH, gives 1-methylcyclopentane-1:3-dicarboxylic acid, m.p. 97° (anhydride, m.p. 81°). J. L. D.

**Determination of the constitution of sesquiterpenes by powerful oxidative degradation.**

**Betulol.** W. TREIBS (Ber., 1936, 69, [B], 1—46).—The unesterified betulol of birch-bud oil (isolated through the non-cryst. H phthalate) has in agreement with Soden *et al.* (A., 1905, i, 174), whereas that obtained by hydrolysis of the betulyl acetate has α<sub>D</sub> −19.5°. Betulol (I) is therefore a mixture of at least two bicyclic, closely related alcohols. The alcoholic group is not exclusively primary, since the oxidation product of tetrahydro-*β*-betulol (Semmler *et al.*, A., 1918, i, 301) is only partly aldehydic. Since both components of the oil behave qualitatively, the following work was per-

formed with the mixture. Treatment of the latter with powdered KMnO<sub>4</sub> in COMe<sub>2</sub> affords small amounts of neutral products, H<sub>2</sub>C<sub>2</sub>O<sub>4</sub> (0.5 mol.), a little AcOH, and an acid mixture (II) oxidised by hot dil. HNO<sub>3</sub> to *betulolic acid* (III) [Me<sub>2</sub> ester, (IV), b.p. 132—136°/18 mm., [α]<sub>D</sub> +48°]. The physical properties of (IV) indicate the presence of a 4-C ring, which is confirmed by the stability of (III) towards oxidants. Protracted action of boiling dil. HNO<sub>3</sub> partly converts (III) into H<sub>2</sub>C<sub>2</sub>O<sub>4</sub> and CO<sub>2</sub>H·CH<sub>2</sub>·CMe<sub>2</sub>·CO<sub>2</sub>H without affecting the properties of the unattacked acid, so that (III) is probably a homocaryophyllenic acid belonging to the *trans*-series, since it is not dehydrated by Ac<sub>2</sub>O or AcCl. Since (II) is transformed by MeOH-H<sub>2</sub>SO<sub>4</sub> and subsequent vac. distillation into the Me<sub>2</sub> ester, b.p. 200—202°/20 mm., α<sub>D</sub> +32°, of a saturated OH-dicarboxylic acid, C<sub>13</sub>H<sub>20</sub>O<sub>5</sub> (V), and by protracted esterification into the ester of unsaturated acids, and since (V) is oxidised by hot dil. HNO<sub>3</sub> to (III), it follows that the side-chain must have the termination ·CH:CH·CH<sub>2</sub>·OH. The structures *A* and *B* for primary

and *sec.* (I) are most probable. The portion of the oil which does not react with *o*-C<sub>6</sub>H<sub>4</sub>(CO)<sub>2</sub>O yields *betulene*, C<sub>15</sub>H<sub>22</sub>, b.p. 130—132°/20 mm., α<sub>D</sub> −78°, a bicyclic sesquiterpene with three double linkings. Treatment of a similar portion with H<sub>3</sub>BO<sub>3</sub> yields the unstable, strongly unsaturated compound, C<sub>15</sub>H<sub>22</sub>O, b.p. 140°/20 mm., α<sub>D</sub> −9.2°. The paraffin of the oil is C<sub>20</sub>H<sub>42</sub>, m.p. 49°. H. W.

**Polyterpenes and polyterpenoids. XCIX.** Primary products of the oxidation at the double linking of sumaresinolic acid and oleanolic acid. L. RUZICKA, H. HOSLI, and K. HOFMANN (Helv. Chim. Acta, 1936, 19, 109—114).—Treatment of sumaresinolic acid (I) with O<sub>3</sub> in 80% AcOH at 80° or with H<sub>2</sub>O<sub>2</sub> in AcOH at room temp. affords the corresponding OH-lactone (II), m.p. 322—324° (decomp.), [α]<sub>D</sub> +8.9° in CHCl<sub>3</sub> with 10% of MeOH. (II) is oxidised

by CrO<sub>3</sub> in AcOH at 50° to *sumaresinonoketolactone* (III), m.p. 311—312°, [α]<sub>D</sub> −24.2° in CHCl<sub>3</sub>, also obtained from (I) and CrO<sub>3</sub> in H<sub>2</sub>SO<sub>4</sub>-AcOH. Acetyl-oleanolic acid is oxidised by H<sub>2</sub>O<sub>2</sub> in AcOH at 80° to the corresponding OH-lactone (IV), m.p. 292—294°, further transformed into the ketolactone (V), m.p. 279—280° (oxime, m.p. 220—221°) (Kitasato, A., 1932, 1035). (IV) differs from the corresponding compound of Aumüller *et al.* (A., 1935, 865) only in the steric configuration of the OH group, since each yields (V) when oxidised. Hydrolysis of (V) with KOH-MeOH affords *hydroxyketodihydro-oleanolic acid*, m.p. 306—307°. H. W.

**Differentiation of sterols from other polyterpene alcohols. Structure of lanosterol and onocerol.** H. SCHULZE (Z. physiol. Chem., 1936, 238, 35—53).—"isoCholesterol" (I) (modified prep.), m.p. 136—137°,  $[\alpha]_D^{25} + 61.9^\circ$  in  $\text{CHCl}_3$ , or its acetate with Se at 320—335° gives 1:2:8-trimethylphenanthrene, a hydrocarbon, m.p. 212—213°, and an alkali-sol. substance, (?) a hydroxytrimethylphenanthrene (Me ether, m.p. 179—180°, b.p. 215—230°/14 mm.), but (I) is largely unchanged by Pt at 300°. Onocerol (II) (modified prep.),  $\text{C}_{30}\text{H}_{50}\text{O}_2$ , dimorphic, m.p. 232° and 202°,  $[\alpha]_D^{25} + 5.04^\circ$  in  $\text{C}_5\text{H}_5\text{N}$  [diacetate (III), m.p. 224°,  $[\alpha]_D^{25} + 28.3^\circ$ ; dibenzoate, m.p. 237—238°,  $[\alpha]_D^{25} + 21.5^\circ$ ; dichloroacetate, m.p. 238—244°,  $[\alpha]_D^{25} + 11.4^\circ$ ; di-3:5-dinitrobenzoate, m.p. 291° (decomp.),  $[\alpha]_D^{25} + 19.3^\circ$ ; dianisate, m.p. 232—234°,  $[\alpha]_D^{25} + 9^\circ$ ; all  $[\alpha]$  are in  $\text{CHCl}_3$ ], gives no  $\text{PhCHO}$  on ozonisation (cf. lit.) and does not resemble  $\text{CH}_2\text{:CHPh}$  or neoergosterol in absorption spectrum, reacts with 2 mols. of  $\text{BzO}_2\text{H}$ , and is difficultly reducible. (III), however, readily absorbs 2H (PtO<sub>2</sub> in AcOH). With Se at 300—320° (II) gives 1:2:5:6- $\text{C}_{10}\text{H}_4\text{Me}_4$ . (I) and (II) thus do not contain a cyclopentanophenanthrene skeleton (the criterion of sterols), but are polyterpenoid. R. S. C.

**Lignin. XI. Pine wood and thiol acids.** B. HOLMBERG (Ber., 1936, 69, [B], 115—119; cf. A., 1935, 1502).—The treatment of pine wood with thiolacetic,  $\alpha$ -thiolpropionic,  $\alpha$ -thiolisobutyric, thiolsuccinic, and  $\alpha$ -thiol- $\alpha$ -methylsuccinic acid is described, but it is difficult to find a theoretical basis for the interpretation of the results. The change appears to proceed in two stages, during the first of which the lignin reacts with the SH-acid giving acids containing S which in the subsequent stage become sol. in  $\text{H}_2\text{O}$  or alkali. H. W.

**Action of ethylene oxide on wood and lignin.** II. N. I. NIKITIN and T. I. RUDNEVA (J. Appl. Chem. Russ., 1935, 8, 1176—1183).—Willstätter lignin treated with 18% NaOH and  $(\text{CH}_2)_2\text{O}$  (I) (2 hr. at 70°, or 2 days at room temp.) yields amorphous hydroxyethyl-lignin (II), containing 38.76% of  $\text{OEt} + \text{OMe}$ , and 5.18% of acetylable OH. (I) is eliminated from (II) by HI at 135—140°, but not by hydrolysis with 5%  $\text{H}_2\text{SO}_4$  (5 hr. at the b.p.), which, however, transforms 21.6% of (I) into a  $\text{H}_2\text{O}$ -sol., non-reducing product. A product apparently identical with (II) is obtained from wood by treatment successively with NaOH and (I), followed by hydrolysis with 5%  $\text{H}_2\text{SO}_4$ . The hygroscopicity and swelling capacity of (II) are > those of lignin. R. T.

**Elemic acid from elemi resin. VIII.  $\beta$ -Elemionic acid.** M. M. MLADENOVIC and I. BERKEŠ (Monatsh., 1935, 67, 36—41; cf. A., 1935, 495).— $\beta$ -Elemionic acid (I), m.p. 220.5° [modified prep. from  $\alpha$ -elemionic acid (II); oxime, m.p. 218°, hydrolysed to (I) by  $\text{HNO}_2$ ], gives (Pd-C in AcOH) a  $\text{H}_4$ -acid (III), m.p. 244° [oxime, m.p. 245°, hydrolysed to (III); also obtained by hydrogenation of crude (II)], and is identical with  $\delta$ -elemic acid (A., 1932, 749). R. S. C.

**Toad poisons. VIII. Dehydrogenation of cinobufagin.** H. JENSEN (J. Amer. Chem. Soc., 1935, 57, 2733—2734).—Dehydrogenation (Se at

310—340°) of cinobufagin (I),  $\text{C}_{25}\text{H}_{26}\text{H}_{32}\text{O}_6$  (cf. A., 1934, 412), gives a little of (probably) methylcyclopentenophenanthrene. (I) and (probably) other bufagins appear to contain the same ring system as the sterols and cardiac aglucones. H. B.

**Carotenoids of purple bacteria. II. Rhodoviolascene.** P. KARRER and U. SOLMSEN (Helv. Chim. Acta, 1936, 19, 3—5; cf. this vol., 248).—Rhodoviolascene is  $\text{C}_{42}\text{H}_{60}\text{O}_2$ . It contains 2 OMe and absorbs 26 H when catalytically hydrogenated. It affords  $\text{COME}_2$  when treated with  $\text{O}_3$ , and hence is probably a  $(\text{OMe})_2$ -derivative of lycopene (I) or similar hydrocarbon. It appears to be optically inactive in  $\text{C}_6\text{H}_6$ . It does not react with  $\text{NH}_2\text{OH}$  or give a  $\text{H}_2$ -derivative by short treatment with  $\text{Zn-AcOH-C}_5\text{H}_5\text{N}$ . The bacteria contain also rhodovibrene, but rhodopurpurin is possibly identical with (I). H. W.

**Preparation and reactions of tertiary tetrahydrofurylcarbinols.** A. L. DOUNCE, R. H. WARDLOW, and R. CONNOR (J. Amer. Chem. Soc., 1935, 57, 2556—2559).—Reduction ( $\text{H}_2$  at 100—130 atm., Raney Ni, 150°) of Et furoate (I) gives 93.3% of Et tetrahydrofuroate (II), b.p. 188—190°/740 mm., which with  $\text{MgPhBr}$  affords diphenyl-2-tetrahydrofurylcarbinol (III), m.p. 79—80°, dehydrated (anhvd.  $\text{MgSO}_4$ ) to 2-benzhydrylidene tetrahydrofuran (IV), b.p. 195°/10 mm., m.p. 107.5—108.5° [ozonolysis products,  $\text{COPh}_2$  and  $\gamma$ -butyrolactone (V)]. Prolonged treatment of (III) with  $\text{MgPhBr}$  (3 equivs.) in xylene does not cause ring fission; hydrolysis and removal of the xylene gives (IV). 2-Tetrahydrofuryl-diethyl-, b.p. 200—203°/740 mm., and -di-n-butyl- (VI), b.p. 151—152°/24 mm., 251—252°/740 mm., -carbinols, best prepared from (II) and  $\text{MgRBr}$ , are also obtained by reduction of 2-furyl-diethyl-, b.p. 92—95°/14 mm., and -di-n-butyl-, b.p. 128—131°/14 mm., -carbinol, respectively [from (I) and  $\text{MgRBr}$ ]. Dehydration ( $\text{MgSO}_4$ -KOH) of (VI) gives an inseparable mixture. (V) is obtained in 10% yield by reduction ( $\text{H}_2$  at 90—130 atm., Cu-Cr-BaO catalyst, 250°) of Et succinate. (V) and  $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$  give a little succinhydrazide and (mainly)  $\gamma$ -hydroxybutyrylhydrazide, m.p. 89—90°. H. B.

**Dicarboxylic acid esters of tetrahydrofurfuryl alcohol.** J. N. BORGLIN (Ind. Eng. Chem., 1936, 28, 35—36).—Tetrahydrofurfuryl alcohol reacts (48 hr.; 170—190°) with the calc. amount of terpinene, maleic, maleic, or phthalic anhydride to form the corresponding acid ester or di-ester. F. N. W.

**Production of furfuraldehyde from xylose solutions by means of hydrochloric acid-sodium chloride systems.** E. I. FULMER, L. M. CHRISTENSEN, R. M. HIXON, and R. L. FOSTER (J. Physical Chem., 1936, 40, 133—141).—Xylose-HCl-NaCl mixtures were refluxed with  $\text{PhMe}$  and the furfuraldehyde (I) yields determined from the  $d$  of the resulting (I)- $\text{PhMe}$  solutions. The yield of (I) diminishes as the concn. of xylose increases, being twice as great for 4% as for 60% xylose. It increases with increasing concn. of NaCl, i.e., it is a linear function of the  $p_{\text{H}}$  or of the activity coeff. of the acid. M. S. B.

**Terpene furoates.** J. N. BORGLIN (Ind. Eng. Chem., 1936, 28, 31—32).—Borneol and fenchyl alcohol heated (40 hr.; 160°) with furoic acid give, respectively, *bornyl*, b.p. 275°/760 mm., and *fenchyl furoate*, b.p. 275°/760 mm., hydrogenated (PtO<sub>2</sub>) to fenchyl tetrahydrofuroate. F. N. W.

**Orientation in the dibenzfuran series.** W. G. BYWATER, E. W. SMITH, G. E. BROWN, and H. GILMAN (Proc. Iowa Acad. Sci., 1934, 41, 166).—Sulphonation and chlorination take place at position 2, nitration at position 3, whilst metals attack in position 4. Rules governing the position of entry of a second substituent are given. Sulphonation of *dibenzfuran-2-sulphonic acid* yields the *-2:8-disulphonic acid*; nitration of 2-bromo- and bromination of 3-nitro-dibenzfuran give the same *7-bromo-3-nitro-dibenzfuran*. Bromination of *3-acetamidodibenzfuran* yields *2-bromo-3-aminodibenzfuran*. CH. ABS. (r)

**Constituents of *Matteucia orientalis*.** II. Constitution of *demethoxymatteucinol*. S. FUJISE and T. NISHI (J. Chem. Soc. Japan, 1934, 55, 1020—1023, 1024—1027; cf. A., 1935, 91).—II. Condensation of dimethylphloroglucinol with cinnamoyl chloride affords *5:7-dihydroxy-6:8-dimethylflavanone*, m.p. 202.7—203°; although the m.p. is lowered about 1° on admixture with *demethoxymatteucinol*, the identity of all other properties leads to the conclusion that they are identical. CH. ABS. (r)

**General method for synthesis of flavonol derivatives.** T. OYAMADA (J. Chem. Soc. Japan, 1934, 55, 1256—1261).—Flavonols are formed when *o*-hydroxychalcones are treated with H<sub>2</sub>O, in the presence of dil. alkali. Several examples are given. *Methoxyflavone* has m.p. 114°. CH. ABS. (r)

**Preparation of homogeneous anthocyanins by chromatographic analysis.** P. KARRER and F. M. STRONG (Helv. Chim. Acta, 1936, 19, 25—28).—Al<sub>2</sub>O<sub>3</sub>, activated by cautious treatment with tap-H<sub>2</sub>O, is a suitable adsorbent for anthocyanins. Since the slightly basic material partly converts the oxonium salt into colour base, carbinol base, and phenolbetaine, a given pigment does not necessarily produce a homogeneous zone. *Paonin*, obtained according to Willstätter *et al.* (A., 1915, i, 288), is found to contain cyanin; the colour of a solution of the pure material and FeCl<sub>3</sub> in EtOH is unchanged by addition of H<sub>2</sub>O. H. W.

**Pigments of cotton flowers.** II.—See this vol., 395.

**Bark of *Terminalia arjuna*.** I. *Arjunin*.—See this vol., 395.

**Catalytic chlorination of dioxan.** J. J. KUCERA and D. C. CARPENTER (J. Amer. Chem. Soc., 1935, 57, 2346—2347).—Dioxan and Cl<sub>2</sub> in presence of a little SnCl<sub>4</sub> or I at 90° give 96.6% of the 2:3-Cl<sub>2</sub>-derivative, chlorinated further (in absence or presence of catalyst) at 145° to 83—85% of a mixture of *s*-(32%) and *as*-Cl<sub>2</sub>-derivatives. H. B.

**Dioxan series.** II. Aryl-substituted dioxans. **Synthesis of *p*-dioxen.** R. K. SUMMERBELL and L. N. BAUER (J. Amer. Chem. Soc., 1935, 57, 2364—2368; cf. A., 1934, 80).—2:3-Diphenyl-, m.p.

49—50°, 2:3-di-*o*-, m.p. 105.7—106.2° (corr.), -*m*-, m.p. 84.2° (corr.), and -*p*-, m.p. 56—57.2° (corr.), -*tolyl*-, 2:3-di-*p*-chlorophenyl-, m.p. 152—153° (corr.), 2:3-di-*p*-anisyl-, m.p. 79—80.2° (corr.), 2:3-di-*α*-naphthyl-, b.p. 255—258°/3—4 mm., 2:3-di-*xylenyl*-, m.p. 144.5—146° (corr.), and 2:3-di-*benzyl*-, m.p. 62.2° (corr.), -*dioxans* are prepared from 2:3-dichlorodioxan (I) and MgRX. The main product from (I) and MgMcBr, MgEtBr, or MgBuBr is *p*-*dioxen* (II),  $\text{O} \begin{array}{c} \text{CH}_2 \cdot \text{CH}_2 \\ \text{CH} = \text{CH} \end{array} \text{O}$ , b.p. 94.2°/749.9 mm. [ozonolysis products, HCO<sub>2</sub>H and C<sub>2</sub>H<sub>4</sub>(OH)<sub>2</sub>]; small amounts of the 2:3-dialkyldioxans (Et<sub>2</sub>, b.p. 164—175°/747.9 mm.; Bu<sub>2</sub>, b.p. 120—122°/16—17 mm.; not characterized) are also produced. (II) and Hal in CCl<sub>4</sub> at 0° give (I) and 2:3-di-*bromodioxan*, m.p. 69—70° (softens at 64°). (I) and HCl at 0° afford *chlorodioxan* (III), b.p. 62—63°/14 mm., which is unstable even at room temp.; in presence of a little BiCl<sub>3</sub>, a polymeride of (II) results. (III) and MgPhBr give *phenyldioxan*, m.p. 45—46°. Chlorination of dioxan (IV) to (I) is considered to occur thus: (IV) → (III) → (II) → (I). H. B.

**Dimorphism of rotenone.** E. L. GOODEN and C. M. SMITH (J. Amer. Chem. Soc., 1935, 57, 2616—2618).—Rotenone exists in two enantiotropic forms, m.p. 163° (stable) and approx. 180° (unstable); optical data are given. H. B.

**6:7-Benzoylene-ββ'-benzofurans from 1:5-di-aryolanthraquinones.** R. SCHOLL and S. HASS (Ber., 1936, 69, [B], 194—197).—1:5-Di-*m*-xyloylantraquinone is transformed by Na<sub>2</sub>S<sub>2</sub>O<sub>4</sub> in boiling 80—85% EtOH in absence of air into *9-hydroxy-1:5-di-m-xyloylanthr-10-one*, m.p. 230° in a preheated bath (pyridinium salt; *p*-bromobenzoate, m.p. 288°), which in indifferent media or when subjected to

pressure passes into an equilibrium mixture with 1:5-di-*m*-xyloylanthraquinol. It is converted by boiling AcOH or conc. H<sub>2</sub>SO<sub>4</sub> at 15—20° into 2-*m*-xylyl-6:7-6'-*m*-xyloxybenzoylene-ββ'-benzofuran (I), m.p. 193°, which is not reduced by Na<sub>2</sub>S<sub>2</sub>O<sub>4</sub> and NaOH and suffers fission of the furan ring with hot C<sub>5</sub>H<sub>5</sub>N-NaOH. H. W.

**Tetrahydroxydibenzothianthrenediquinone; chemistry of naphthazarin.** K. BRASS, R. PFLUGER, and K. HONSBURG (Ber., 1936, 69, [B], 80—87).—The interaction of Na<sub>2</sub>S (1.5 mols.) with dibromonaphthazarin (I) does not proceed as smoothly as with 2:3-dichloro-*α*-naphthaquinone, but gives Na<sub>1</sub>, Na<sub>3</sub>, and Na<sub>5</sub> derivatives converted by dil. acid into *tetrahydroxydibenzothianthrenediquinone* (II; R=S), m.p. > 300°, best obtained from (I) and Na<sub>2</sub>S (1 mol.) at 200°. (II) cannot be acetylated, but is reduced and then benzoylated to *octabenzoyldibenzothianthren*, m.p. 283°. It is not attacked by cold conc. or fuming HNO<sub>3</sub> and is completely oxidised by the hot reactants. The complex course of the prep. is shown by the occasional formation of the compound (II; R=S-S). *Dibromonaphthazarin Me<sub>2</sub> ether* (III), m.p. 179—180°, and Na<sub>2</sub>S give products containing

Br from which a homogeneous material could not be isolated. 2:3-Dibromonaphthazarin is best obtained

by the action of a slight excess of Br on naphthazarin in AcOH; it does not react with  $\text{CH}_3\text{N}_2$  or  $\text{Me}_2\text{SO}_4$ , but is transformed by  $p\text{-C}_6\text{H}_4\text{Me}\cdot\text{SO}_3\text{Me}$  and anhyd.  $\text{Na}_2\text{CO}_3$  in  $o\text{-C}_6\text{H}_4\text{Cl}_2$  at  $170^\circ$  into (III). Under similar conditions naphthazarin affords the  $\text{Me}_2$  ether, m.p.  $160^\circ$ . Reasons are advanced for assigning the above constitution to (III) and for considering its reduction product to be 2:3-dibromo-1,4-dihydroxy-5:8-dimethoxynaphthalene. H. W.

**Syntheses by means of magnesylpyrroles.**  
**Series II. XXI.** B. ODDO and G. ACUTO (Gazzetta, 1935, 65, 1029—1036).—Mg 2:5-dimethylpyrrol bromide in  $\text{Et}_2\text{O}$  with  $\text{AcCl}$  yields 3-acetyl-2:5-dimethylpyrrole, m.p.  $89^\circ$  [semicarbazone, m.p.  $234^\circ$  (decomp.)]. The 3-propionyl, m.p.  $102.5^\circ$  [semicarbazone, m.p.  $197^\circ$  (decomp.)], 3-butyryl, m.p.  $60^\circ$ , and 3-benzoyl, m.p.  $132^\circ$ , compounds are similarly prepared. With  $\text{CO}_2\text{Et}\cdot\text{COCl}$ , Et 2:5-dimethylpyrrol-3-glyoxylate, m.p.  $83.5^\circ$ , is obtained, hydrolysed to the acid, m.p.  $196\text{--}197^\circ$  (decomp.) ( $\text{NH}_4$ ,  $\text{Pb}$ , and other salts); this gives, when heated, an aldehyde, and, with  $\text{EtOH}\cdot\text{NH}_3$  at  $120^\circ$ , 2:5-dimethylpyrrol-3-glyoxamide, m.p.  $225^\circ$  (decomp.). E. W. W.

**Occurrence of piperidine in black pepper.**—See this vol., 395.

**Action of ultra-violet light on pyridine. VI.**  
**Reactions of photopyridine and behaviour of pyridine derivatives in the region of ultra-violet radiations.** H. FREYTAG (Ber., 1935, 69, [B], 32—40; cf. A., 1934, 303).—Dil. alkaline  $\text{KMnO}_4$  is unsuitable for the detection of photopyridine [ $\text{NH}_4$  salt of enolglutacondialdehyde (I)], since irradiation of  $\text{H}_2\text{O}$  causes formation of  $\text{H}_2\text{O}_2$ . The applicability of dimedon (I), 1-phenyl-3-methylpyrazol-5-one (II), and indole (III) has therefore been tested with the Na salt of (I); coloured derivatives are obtained which could not be completely purified. Anaesthesin (IV), however, yields glutacondianæstheside, m.p. about  $154\text{--}155^\circ$ . The effect of irradiation of  $\text{C}_5\text{H}_5\text{N}$ , 2-, 3-, and 4-methyl-, 2:4- and 2:6-dimethyl-, 2:4:6-trimethyl-, and 2-benzyl-pyridine in presence of (I), (II), (III), and (IV), respectively, is tabulated, whereby it appears that Me in position 3 hinders the photo-reaction. Several  $\text{C}_5\text{H}_5\text{N}$  derivatives become coloured yellow to yellowish-brown in  $\text{H}_2\text{O}$  or  $\text{EtOH}$ , but do not give an aldehydic reaction. Substances with halogen and carbalkoxy-groups become hydrolysed and give halogen ions. 5-Bromo-3-aminopyridine becomes very rapidly discoloured with elimination of Br; since discoloration commences at the boundary of solution and air a photo-oxidative attack on the  $\text{NH}_2$  appears to occur. This applies also to 5-amino-

2-methylpyridine, whereas 5-aminopyridine-3-carboxylic acid is unaffected. 4-Chloropicolinic acid and 4-chloro-2-aminopyridine are resistant to irradiation, whilst pyridine-2:3-dicarboxylic acid and -3-carboxydiethylamide are completely unchanged. The behaviour of  $\cdot\text{CHO}$  in 5:6-dichloropyridine-3- and 4:6-dichloropyridine-2-aldehyde is uncertain. 4-Iodopyridine-2-carboxylic acid yields I formed by photo-oxidation of primarily-formed HI.  $\text{Et}_2$  2:6-dimethylpyridine-3:5-dicarboxylate is rapidly hydrolysed. H. W.

**Alkylated benzeneazoaminopyridines.**—See B., 1936, 124.

**Aldehydes of the indole series.**—See B., 1936, 140.

**Condensation of indolealdehydes with hippuric acid.** E. RESTELLI (Anal. Assoc. Quim. Argentina, 1935, 23, 58—62).—Indole-3-aldehyde and hippuric acid, when heated with  $\text{NaOAc}$  in addition to  $\text{Ac}_2\text{O}$ , give 2-phenyl-4-(1'-acetylindolylidene)oxazolone, m.p.  $205^\circ$  (2'-Me derivative, m.p.  $185^\circ$ ). F. R. G.

**Catalytic decomposition of ethyl propyl ketone phenylhydrazone.** A. E. ARBUSOV and I. A. ZAITZEV (Trans. Butlerov Inst. Chem. Tech. Kazan, 1934, No. 1, 33—38; cf. A., 1932, 1236).—A substance,  $\text{C}_{12}\text{H}_{15}\text{N}$ , b.p.  $167/15$  mm. (picrate, m.p.  $144^\circ$ ), is obtained, which may be either 2:3-diethyl- or 2-methyl-3-propyl-indole. CH. ABS. (r)

**Quinolone-acids from oxindole derivatives.**  
 E. ZRIKE and H. G. LINDWALL (J. Amer. Chem. Soc., 1936, 58, 49—50).—Isatin (I) and  $\text{CH}_2\text{Ph}\cdot\text{CO}_2\text{Et}$  in  $\text{EtOH}\cdot\text{NH}_4\text{Et}$  at room temp. for 5 days give 3-hydroxy-3- $\alpha$ -carbethoxybenzylloxindole, m.p.  $154\text{--}156^\circ$ , converted by warm 1%  $\text{NaOH}$  into (I) and by conc.  $\text{HCl}$  in  $\text{EtOH}$  into 2-keto-3-phenyl-1:2-dihydroquinoline-4-carboxylic acid. 3-(Dicyanomethylene)oxindole (II) (Walter, A., 1902, i, 373) is reduced (aq.  $\text{Na}_2\text{S}_2\text{O}_4$ ) to 3-(dicyanomethyl)oxindole, m.p.  $183\text{--}185^\circ$  (darkens about  $160^\circ$ ), which is unstable in hot solvents and is converted by 10%  $\text{NaOH}$  (or acid) into 2-keto-1:2:3:4-tetrahydroquinoline-4-carboxylic acid (III).  $\text{CN}\cdot\text{CH}_2\cdot\text{CO}\cdot\text{NH}_2$  and (I) in  $\text{EtOH}$ -piperidine afford 3-(cyanoformamidomethylene)oxindole, m.p.  $248\text{--}250^\circ$ ; this and (II) are hydrolysed (conc.  $\text{HCl}$ ) to a dibasic acid,  $\text{C}_{11}\text{H}_7\text{O}_5\text{N}$ , m.p.  $>340^\circ$  ( $\text{Ag}_2$  salt; ester, m.p.  $150\text{--}151^\circ$ ), also formed from  $\text{Et}_3\text{O}$  oxindole-3:3-dimalonate (A., 1935, 758) and 10%  $\text{NaOH}$ , which is reduced ( $\text{Zn}$ ,  $\text{AcOH}$  or  $\text{Na}\text{--Hg}$ ,  $\text{H}_2\text{O}$ ) to (II). H. B.

**Amino-compounds of the quinoline series.**—See B., 1936, 92.

**Preparation of 4-alkyl- and 4-aryl-quinolines.**  
 J. KENNER and F. S. STATHAM (Ber., 1936, 69, [B], 16—18).—The following % yields of 4-arylquinoline are obtained from the requisite arylamine and  $\alpha$ -ketone (cf. Blaise *et al.*, A., 1907, i, 241) without and with  $\text{PhNO}_2$  (1 mol.),  $\text{As}_2\text{O}_5$  (0.5 mol.),  $\text{SnCl}_4\cdot 8\text{H}_2\text{O}$  (1 mol.), and  $\text{FeCl}_3\cdot 6\text{H}_2\text{O}$  (2 mols.) as oxidising agent: 4-phenyl (10, —, —, 52.6, —);  $p$ -tolyl (7, 9, 14, 36.6, 44.6); 2-methoxy-5-methylphenyl (5, —, —, 1.5, —), and  $\beta$ -naphthyl (—, —, —, 41, —) quinoline. The respective % yields of 4-alkylquinolines with  $\text{PhNO}_2$  (1 mol.),  $\text{SnCl}_4$  (1 mol.),  $\text{SnCl}_4\cdot 8\text{H}_2\text{O}$  (1 mol.),

and  $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$  (2 mols.) as oxidants are as follows: Me- (28, 21, 40, 35—40); Et- (20, —, 40, —); Pr<sup>n</sup>- (25, —, 40, —); Bu<sup>n</sup>- (28, —, 40, —).

$\text{CH}_2\text{Cl} \cdot \text{CH}_2 \cdot \text{COCl}$ , and  $\text{AlCl}_3$  in  $\text{CS}_2$  afford  $\beta$ -chloroethyl 2-naphthyl ketone, m.p.  $83^\circ$ , converted by KOH at  $280^\circ$  into  $2\text{-C}_{10}\text{H}_7\text{-CO}_2\text{H}$  and by  $\text{NHPH-NH}_2$  in warm EtOH into 1-phenyl-3- $\beta$ -naphthylpyrazoline, m.p.  $181\text{--}182^\circ$ . The picrates, m.p.  $200^\circ$  (decomp.),  $205^\circ$  (decomp.), and  $185\text{--}189^\circ$  (decomp.), of 4-ethyl-, 4-n-propyl-, and 4-n-butyl-quinoline, respectively, are described.

**Tetrahydrocarbazoles with substituents in the 7-position.** S. G. P. PLANT and (Miss) K. M. ROGERS (J.C.S., 1936, 40—41).—9-Acetyltetrahydrocarbazole (I),  $\text{AcBr}$ , and  $\text{AlCl}_3$  give 7:9-diacetyltetrahydrocarbazole (II), m.p.  $110^\circ$ , hydrolysed to 7-acetyltetrahydrocarbazole (S) to 2-acetylcarbazole and reduced ( $\text{Zn-Hg}$ ) to 7-ethylhexahydrocarbazole, m.p.  $44\text{--}46^\circ$ . (I) and  $\text{BzCl}$  afford 7-benzoyl-9-acetyl-, m.p.  $126^\circ$ , hydrolysed to 7-benzoyl-, m.p.  $165^\circ$ , which is also obtained from 1,3-dibenzoyl-tetrahydrocarbazole, m.p.  $121^\circ$ . 9-Benzoyl-7-acetyltetrahydrocarbazole, m.p.  $149^\circ$ , hydrolysed to (II), is similarly obtained.

F. R. S.

**Chemotherapeutic studies in the acridine series.** I. 2:6- and 2:8-Diaminoacridines. A. ALBERT and W. H. LINNELL (J.C.S., 1936, 88—93).—Na 2-chloro-4-nitrobenzoate,  $m\text{-NO}_2\text{-C}_6\text{H}_4\text{-NH}_2$ , and Cu yield 5:5'-dinitrodiphenylamine-2-carboxylic acid (I), m.p.  $263^\circ$  (Ag salt), reduced ( $\text{SnCl}_2\text{-HCl}$ ) to 3:3'-diaminodiphenylamine, m.p.  $94\text{--}95^\circ$  ( $\text{Ac}_2$  derivative), also obtained by reduction of 3:3'-dinitrodiphenylamine, m.p.  $186\text{--}5^\circ$ . Ring-closure of (I) yields a mixture of 5-chloro-2:6- (II), m.p.  $200\text{--}203^\circ$  (principally), and 2:8-dinitroacridine (III), with 2:8-dinitroacridone. (II) is hydrolysed ( $\text{HCl}$ ) to 2:6-dinitroacridone, reduced to the 2:6- $(\text{NH}_2)_2$ -compound ( $+0\text{.5H}_2\text{O}$ ), m.p.  $306^\circ$ , which with  $\text{H}_2$  gives 2:6-diaminoacridine, m.p.  $213\text{--}216^\circ$  (p.). 2:8-Diaminoacridine, obtained from (III), forms dibenzylidene, m.p. approx.  $370^\circ$  (decomp.), above  $350^\circ$ , and  $\text{Bz}_2$  derivatives, m.p. above  $350^\circ$ .

F. R. S.

**10-Hydroxyacridone and "acridol."** II. A. KIEGL and A. BRÖSAMLE (Ber., 1936, 69, [B], 197—202; cf. A., 1914, i, 867).—Oxidation of acridine (I) in  $\text{C}_6\text{H}_6$  with  $\text{BzO}_2\text{H}$  affords acridine 10-oxide, identical with "acridol" (loc. cit.; cf. Tanasescu et al., A., 1934, 1010; Lehmnstedt, A., 1935, 1251). Similar treatment of 5-methoxyacridine gives 5-methoxyacridine 10-oxide (II), m.p. about  $158^\circ$  (also  $+1\text{H}_2\text{O}$ ), which is not identical with the Me ether obtained by methylation of 10-hydroxyacridone (III) (Kiegl, loc. cit.). Both ethers give 10-hydroxyacridone when treated with  $\text{HCl}$  and decompose at about the same temp. into  $\text{CH}_2\text{O}$  and (I), but (II) is pronouncedly basic and dissolves readily in  $2\text{N-HCl}$  at  $15\text{--}20^\circ$ . (III) is tautomeric, the free compound passing under the influence of alkali into 5-hydroxyacridine 10-oxide.

**2:8-Dialkoxy-10-alkylacridinium derivatives with various kinds of amino-groups on the 5-carbon atom.** V. Synthesis of 5-amino-2:8-dialkoxy-10-alkylacridinium hydroxides. VI.

**Synthesis of 5-amino-2:8-dialkoxy-10-alkylacridinium iodides.** VII. Synthesis of 5-amino-2:8-dialkoxy-10-alkylacridinium oxalates. VIII. Synthesis of 5-amino-2:8-dialkoxy-10-alkylacridinium derivatives and 5-(2':8'-dialkoxy-N'-alkylacridonamino)-2:8-dialkoxy-10-alkylacridinium derivatives. IX. Synthesis of (2':8'-dialkoxy-10'-alkyl-10'-substituted-acridine)-5:5'-ethylenediamino-2:8-dialkoxy-10-alkylacridinium derivatives. K. ISHIIHARA (J. Chem. Soc. Japan, 1934, 55, 945—958, 1028—1039, 1040—1050, 1185—1206, 1277—1294; cf. A., 1935, 1132).—V. The following 5-anilino-, 5-o-, -m-, and -p-toluidino-, and 5-p-phenetidin-derivatives of substituted-acridinium hydroxides have been prepared by hydrolysis of the chlorides: 2:8-dimethoxy-10-methyl-, m.p.  $148\text{--}149^\circ$ ,  $133\text{--}134^\circ$ ,  $137\text{--}138^\circ$ ,  $133\text{--}134^\circ$ ,  $180^\circ$ ; 2:8-dimethoxy-10-ethyl-, m.p.  $145\text{--}146^\circ$ ,  $157\text{--}158^\circ$ ,  $165\text{--}166^\circ$ ,  $167\text{--}168^\circ$ ,  $154\text{--}155^\circ$ ; 2:8-diethoxy-10-methyl-, m.p.  $164\text{--}165^\circ$ ,  $131\text{--}132^\circ$ ,  $172\text{--}173^\circ$ ,  $158\text{--}159^\circ$ ,  $167\text{--}168^\circ$ ; 2:8-diethoxy-10-ethyl-, m.p.  $156^\circ$ ,  $138\text{--}139^\circ$ ,  $176^\circ$ ,  $174\text{--}175^\circ$ ,  $171^\circ$ .

VI. The -acridinium iodide derivatives (as above) are obtained from the hydroxides and  $\text{AcOH-KI}$ : 2:8-dimethoxy-10-methyl-, m.p.  $237\text{--}238^\circ$ ,  $236\text{--}237^\circ$ ,  $243\text{--}244^\circ$ ,  $253\text{--}254^\circ$ ,  $238^\circ$ ; 2:8-dimethoxy-10-ethyl-, m.p.  $249^\circ$ ,  $224\text{--}225^\circ$ ,  $243\text{--}245^\circ$ ,  $230\text{--}231^\circ$ ,  $227\text{--}228^\circ$ ; 2:8-diethoxy-10-methyl-, m.p.  $252\text{--}253^\circ$ ,  $248^\circ$ ,  $263^\circ$ ,  $257^\circ$ ,  $251^\circ$ ; 2:8-diethoxy-10-ethyl-, m.p.  $255^\circ$ ,  $248^\circ$ ,  $262^\circ$ ,  $274^\circ$ ,  $234\text{--}235^\circ$ .

VII. Similarly the corresponding 20 oxalates are prepared from the hydroxides and  $\text{H}_2\text{C}_2\text{O}_4$  in  $\text{AcOH}$ ; respective m.p., in the order given above, are  $232^\circ$ ,  $214\text{--}215^\circ$ ,  $220\text{--}221^\circ$ ,  $214\text{--}215^\circ$ ,  $180^\circ$ ;  $206\text{--}207^\circ$ ,  $200\text{--}201^\circ$ ,  $204\text{--}205^\circ$ ,  $184\text{--}185^\circ$ ,  $209^\circ$ ;  $231\text{--}232^\circ$ ,  $210\text{--}211^\circ$ ,  $212\text{--}213^\circ$ ,  $224\text{--}226^\circ$ ,  $202\text{--}203^\circ$ ,  $212^\circ$ ,  $234\text{--}235^\circ$ ,  $212\text{--}214^\circ$ ,  $212^\circ$ ,  $218\text{--}219^\circ$ .

VIII. 5-Amino-2:8-dimethoxy-10-methylacridinium chloride (I), m.p.  $324\text{--}325^\circ$ , is prepared from the 5-Cl-compound with aq.  $\text{NH}_3$ . The corresponding hydroxide, m.p.  $74\text{--}78^\circ$ , iodide, m.p.  $339\text{--}340^\circ$  and oxalate, m.p.  $252\text{--}253^\circ$ , are described. (I), with  $\text{AcOH}$ , yields 2:8-dimethoxy-5-(2':8'-dimethoxy-N'-methylacridonamino)-10-methylacridinium chloride, m.p.  $269\text{--}270^\circ$ . The following are prepared similarly: 5-amino-2:8-dimethoxy-10-ethylacridinium chloride, m.p.  $282\text{--}283^\circ$  (hydroxide, m.p.  $140\text{--}142^\circ$ ; iodide, m.p.  $294^\circ$ , oxalate, m.p.  $190^\circ$ ); 2:8-dimethoxy-5-(2':8'-dimethoxy-N'-ethylacridonamino)-10-ethylacridinium iodide, m.p.  $295^\circ$ ; 5-amino-2:8-diethoxy-10-methylacridinium chloride, m.p.  $311\text{--}312^\circ$  (hydroxide, m.p.  $153\text{--}154^\circ$ ; iodide, m.p.  $312^\circ$ ; oxalate, m.p.  $228^\circ$ ); 2:8-diethoxy-5-(2':8'-diethoxy-N'-methylacridonamino)-10-methylacridinium chloride, m.p.  $287\text{--}288^\circ$  (iodide, m.p.  $288\text{--}290^\circ$ ); 5-amino-2:8-diethoxy-10-ethylacridinium chloride, m.p.  $294\text{--}295^\circ$  (hydroxide, m.p.  $149\text{--}150^\circ$ ; iodide, m.p.  $303^\circ$ ; oxalate, m.p.  $237\text{--}238^\circ$ ); 2:8-diethoxy-5-(2':8'-diethoxy-N'-ethylacridonamino)-10-ethylacridinium chloride, m.p.  $218^\circ$  (iodide, m.p.  $269^\circ$ ).

IX. 5-Chloro-2:8-dimethoxy-10-methylacridinium chloride with  $(\text{CH}_2\text{NH}_2)_2$  yields (10'-hydroxy-2':8'-dimethoxy-10'-methylacridino)-5:5'-ethylenediamino-2:8-dimethoxy-10-methylacridinium hydroxide, m.p.  $230^\circ$  (tetrapicrate, m.p.  $231\text{--}232^\circ$ ); this with  $\text{AcOH}$

affords (10'-chloro-2': 8'-dimethoxy-10'-methylacridino)-5 : 5'-ethylenediacetamido-2 : 8-dimethoxy-10-methylacridinium chloride, m.p. 250°. The 10'-chloro-chloride, m.p. 231—232°, 10'-iodo-iodide, m.p. 282—283°, and 10'-oxalato-oxalate, m.p. 233—234°, are obtained similarly. The following are described: (10'-hydroxy-2': 8'-dimethoxy-10'-ethylacridino)-5 : 5'-ethylenediamino-2 : 8-dimethoxy-10-ethylacridinium hydroxide, m.p. 218—220°, and the derived 10'-chloro-chloride, m.p. 253°, 10'-iodo-iodide, m.p. 271—272°, and 10'-oxalato-oxalate, m.p. 235°; (10'-hydroxy-2': 8'-diethoxy-10'-methylacridino)-5 : 5'-ethylenediamino-2 : 8-diethoxy-10-methylacridinium hydroxide, m.p. 236—238°, and the derived 10'-chloro-chloride, m.p. 267—268°, 10'-iodo-iodide, m.p. 290°, and 10'-oxalato-oxalate, m.p. 253°; (10'-hydroxy-2': 8'-diethoxy-10'-ethylacridino)-5 : 5'-ethylenediamino-2 : 8-diethoxy-10-ethylacridinium hydroxide, m.p. 204—206°, and the derived 10'-chloro-chloride m.p. 241—242°, and 10'-oxalato-oxalate, m.p. 249—250°. CH. ABS. (r)

**Action of alkalis and alkali salts on antipyrine.** L. E. HARRIS and E. D. TEBOW (J. Amer. Pharm. Assoc., 1935, 24, 1069—1070).—The immiscible liquid obtained on the addition of antipyrine to conc. solutions of alkalis or alkali salts is apparently an isomeride. E. H. S.

**Derivatives of 1 : 3-diaryl-5-pyrazolones and of 1 : 1'-diaryl-3 : 3'-arylene-5 : 5'-bispyrazolones.**—See B., 1936, 92.

**Alkylglyoxalidines.** H. C. CHITWOOD and E. E. REID (J. Amer. Chem. Soc., 1935, 57, 2424—2426).—2-Methylglyoxalidine (I), m.p. 105° (205°), obtained in 68% yield when  $(\text{CH}_2\text{NHAc})_2$  is heated with Mg powder at 270°, is hydrolysed (aq. alkali) to  $(\text{CH}_2\text{NH}_2)_2$ . 2-Ethyl-, m.p. 38.1° (137.1°), 2-propyl-, m.p. 35.3° (129°), 2-butyl-, m.p. 41° (125.8°), 2-amyl-, m.p. 33.8° (128.4°), 2-hexyl-, m.p. 46.2°, 2-heptyl-, m.p. 60° (104.8°), 2-octyl-, m.p. 52.1°, 2-nonyl-, m.p. 71.4° (122°), 2-decyl-, m.p. 79.5° (82°), and 2-undecyl-, m.p. 79.8° (61.5°), glyoxalidines are similarly obtained (in some cases Mg is replaced by Na) in 5.6—49% yield from the appropriate  $(\text{CH}_2\text{NH}\cdot\text{COR})_2$ . The temp. given in parentheses are m.p. of the picrates; the aurichlorides are analysed. The toxicity (towards *Lupinus albus* and animals) of the first 5 compounds decreases with increase in size of the alkyl group. (I) and Br in  $\text{CHCl}_3$  give (probably) the N-Br-derivative hydrobromide, hydrolysed ( $\text{H}_2\text{O}$ ) to (I). H. B.

**Preparations of methyl  $\beta$ -( $\zeta$ -methyl- $\Delta^7$ -heptenyl)amine.**—See B., 1936, 124.

**Piperazine.** VIII. Condensation with aldehydes. W. T. FORSEE, jun., and C. B. POLLARD (J. Amer. Chem. Soc., 1935, 57, 2363—2364).—Piperazine (I) and RCHO in presence or absence of solvent give insol. products of the type  $(\text{N} < \begin{smallmatrix} \text{C}_6\text{H}_4 \\ \text{C}_6\text{H}_5 \end{smallmatrix} > \text{N}\cdot\text{CHR})_n$ ; those where R=H, m.p. > 300° [also formed from (I) and  $\text{CH}_3\text{I}$ , Ph, m.p. 270° (decomp.)] [also formed from (I) and  $\text{CHPhCl}_2$ ], *o*-OH- $\text{C}_6\text{H}_4$ , m.p. 210° (decomp.), *p*- $\text{C}_6\text{H}_4\text{Me}$ , m.p. 275° (decomp.), *o*- $\text{C}_6\text{H}_4\text{Cl}$ , m.p. 240° (decomp.), and *p*-OMe- $\text{C}_6\text{H}_4$ , m.p. 290° (decomp.), are described. N-Phenylpiperazine with

$\text{CH}_3\text{O}$ , MeCHO, PhCHO, *o*- $\text{C}_6\text{H}_4\text{Me}\cdot\text{CHO}$ , and *o*-OMe- $\text{C}_6\text{H}_4\cdot\text{CHO}$  gives di-(N-phenyl-N'-piperazyl)-methane, m.p. 123—124° (also formed using  $\text{CH}_3\text{I}_2$ ), -ethane, m.p. 121—123°, -phenylmethane, m.p. 125—126°, -*o*-tolylmethane, m.p. 144—144.5°, and -*o*-anisylmethane, m.p. 135—136°, respectively. H. B.

**Synthesis of 6-amino-4-ethylpyrimidine.** W. T. CALDWELL and W. M. ZIEGLER (J. Amer. Chem. Soc., 1936, 58, 78—79).—6-Hydroxy-2-ethylthiol-4-ethylpyrimidine [best prepared from  $\text{EtCO}\cdot\text{CH}_2\cdot\text{CO}_2\text{Et}$  and  $\text{SEt}\cdot\text{C}(\text{NH})\cdot\text{NH}_2$ , HBr in MeOH-KOH at 0°] is hydrolysed to 4-ethyluracil, m.p. 204—205°, converted by POCl<sub>3</sub> into 2 : 6-dichloro-4-ethylpyrimidine, b.p. 90—95°/4 mm., 103—107°/7 mm., which with red P and HI (b.p. 127°) gives 6-hydroxy-4-ethylpyrimidine hydriodide, m.p. 170.5—171.5° (sinters at 160°). This with POCl<sub>3</sub> affords 6-chloro-4-ethylpyrimidine, b.p. 193°, which with EtOH-NH<sub>3</sub> at 150° gives 6-amino-4-ethylpyrimidine (+3H<sub>2</sub>O), m.p. 47.5—48°, m.p. (anhyd.) 87.5—88° (picrate, m.p. 204—205°; hydrochloride, m.p. 198—199°; aurichloride, m.p. 150—151°). H. B.

**Reaction products of aromatic amidines with diketones, dialdehydes, and their monoximes.** J. B. EKELEY and J. L. ELLIOTT (J. Amer. Chem. Soc., 1936, 58, 163—164).—The following 5-hydroxy-2-phenyl-4-arylpyrimidines are prepared (cf. A., 1936, 1133) from  $\text{NH}_2\cdot\text{CPh}\cdot\text{NH}$  (I),  $(\text{CHO})_2$ , and the appropriate ArCHO in aq. EtOH-KOH at room temp.: 4-*o*-carboxyphenyl, m.p. 259—260°; 4-*o*-, m.p. 260°, and -*p*-, m.p. 305—306°, -chlorophenyl; 4-2' : 4', m.p. 248—249°, -2' : 5', m.p. 268—269°, and -3' : 4', m.p. 259—260°, -dimethoxyphenyl; 4-*p*-dimethylamino-phenyl, m.p. 277—278°, 4-*p*-phenetyl, m.p. 292—293°; 4-*m*-hydroxyphenyl, m.p. 265—265.5°; 4-dibromo-*o*-hydroxyphenyl, m.p. 311°; 4-*o*-hydroxybenzyl, m.p. 287—288°; 4-5'-nitro-2'-hydroxyphenyl, m.p. > 300°; 4-*p*-cumyl, m.p. 246—247°; 4-6'-methoxy-*m*-tolyl, m.p. 253—254°; 4-3' : 4'-methylenedioxyphenyl, m.p. 283—287°; 4-*m*-tolyl, m.p. 237—238°. The following 5-hydroxy-2-*m*-tolyl-4-arylpyrimidines are similarly prepared from  $(\text{CHO})_2$ , *m*- $\text{C}_6\text{H}_4\text{Me}\cdot\text{C}(\text{NH})\cdot\text{NH}_2$  (II) and ArCHO : 4-2' : 4', m.p. 250—251°, -2' : 5', m.p. 229—230°, and -3' : 4', m.p. 238—239°, -dimethoxyphenyl; 4-*p*-phenetyl, m.p. 237—238°; 4-*p*-cumyl, m.p. 263—264°; 4-*o*-, m.p. 272—273°, and -*p*-, m.p. 229°, -anisyl; 4-3' : 4'-methylenedioxyphenyl, m.p. 4-6'-methoxy-*m*-tolyl, m.p. 237—239°. Phenanthraquinone with (I), (II), and *o*- $\text{C}_6\text{H}_4\text{Me}\cdot\text{C}(\text{NH})\cdot\text{NH}_2$  (hydrochlorides) in 50% alkali gives compounds:  $\text{C}_{21}\text{H}_{14}\text{ON}_2$ , m.p. 277—278°,  $\text{C}_{22}\text{H}_{16}\text{ON}_2$ , m.p. 269—270°, and  $\text{C}_{22}\text{H}_{16}\text{ON}_2$ , m.p. 287.5—288°, respectively. (I) and (II) with  $\text{CAcMe}\cdot\text{N}\cdot\text{OH}$  similarly afford compounds,  $\text{C}_{15}\text{H}_{22}\text{O}_4\text{N}_4$ , m.p. 105—107°,  $\text{C}_{16}\text{H}_{24}\text{O}_4\text{N}_4$ , m.p. 94—96°, respectively. Phenanthraquinoneoxime (in amyl alcohol) with (I), (II), *p*- $\text{C}_6\text{H}_4\text{Me}\cdot\text{C}(\text{NH})\cdot\text{NH}_2$  (in  $\text{CHCl}_3$ +KOH) gives compounds,  $\text{C}_{21}\text{H}_{17}\text{O}_2\text{N}_3$ , m.p. 186°,  $\text{C}_{22}\text{H}_{19}\text{O}_2\text{N}_3$ , m.p. 165—166°, and  $\text{C}_{22}\text{H}_{19}\text{O}_2\text{N}_3$ , m.p. 182—183°, respectively. A compound,  $\text{C}_{16}\text{H}_{16}\text{O}_2\text{N}_3$ , m.p. 182—183°, is described. U. B.

**Synthesis of nitrated 2 : 3-dihydropyrimidinazole.** O. BREMER (Annalen, 1936, 521, 286—287).—With  $\text{SOCl}_2$ , 3-nitro-4- $\beta$ -hydroxyethylaminopyrimidine gives the 4- $\beta$ -chloroethylamino-compound, m.p.

reduced ( $\text{Na}_2\text{S}_2\text{O}_4$ ) to 3-amino-4- $\beta$ -chloroethylamino-pyridine, m.p. 85–80°. 3-Nitro-4- $\beta$ -hydroxyethoxy-pyridine, m.p. 112–113° [from 4-chloro-3-nitropyridine, Na and  $(\text{CH}_2\cdot\text{OH})_2$ ], similarly affords the 4- $\beta$ -chloroethoxy-compound, m.p. 70–71°, sinters 44°. 4-Chloro-3-nitropyridine, m.p. 74–75° (lit. m.p. 45°), is reduced ( $\text{Na}_2\text{S}_2\text{O}_4$ ) to the 3- $\text{NH}_2$ -compound, m.p. 82°. 2-Chloro-5-nitropyridine (I) and its 3-Br-derivative with  $\text{NH}_2\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{OH}$  in EtOH at 100° give, respectively, o-nitro-2- $\beta$ -hydroxyethylaminopyridine (II), m.p. 131–132° (hydrochloride, m.p. 182°), and its 3-Br-derivative (III), m.p. 136°; 2-chloropyridine gives 2- $\beta$ -hydroxyethylamino-, m.p. 65° (hydrochloride, m.p. 158.5°), converted by  $\text{SOCl}_2$  into 2- $\beta$ -chloroethylamino-pyridine (IV) (hydrochloride, m.p. 146°). (I) and  $(\text{CH}_2\cdot\text{OH})_2\text{-Na}$  give 5-nitro-2- $\beta$ -hydroxyethoxy-, m.p. 113–114°, converted ( $\text{SOCl}_2$ ) into 2- $\beta$ -chloroethoxy-pyridine, m.p. 131–132°, converted by  $\text{NH}_4\text{Et}$  into 5-nitro-2- $\beta$ -diethylaminoethoxy-pyridine, b.p. 170°/3 mm. [reduced by  $\text{SnCl}_4$  and condensed with  $p\text{-NMe}_2\cdot\text{C}_6\text{H}_4\cdot\text{CHO}$  to give the 5- $p$ -dimethylaminobenzylideneamino-derivative, m.p. 163–164 (picrate, m.p. 131°)], also obtained from (I) and  $\text{NEt}_2\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{ONa}$  in  $\text{Et}_2\text{O}$ . Similarly (I) and the appropriate base afford o-nitro-2- $\beta$ -amino-enylamino-, m.p. 123°, 2- $\beta$ -(diethylamino)ethylamino-, 2- $\beta$ -hydroxydiethylamino- (V), m.p. 59–60°, and 2-allylamino-, m.p. 97° [converted by  $\text{HBr}$  to 2- $\beta$ -bromopropylamino- (VI)], pyridine. (VI) is converted by warming in  $\text{H}_2\text{O}$  into 5-nitro-3-methyl-2:3-dihydropyriminazole, m.p. 185°. Gentle heat converts (IV) into dihydropyriminazolium chloride, converted by  $\text{KOH}$  into 2:3-dihydropyriminazole, m.p. 64–65° (picrate, m.p. 213°), also obtained by the action of  $\text{SOCl}_2$  and alkali on 1- $\beta$ -hydroxyethylpyridoneimine (Kunjanaz, A., 1935, 627).  $\text{SOCl}_2$  converts (II), (III), and (V) into, respectively, 5-nitro- (VII), m.p. 258° (decomp.) (chloride, not melting at 280°), 7-bromo-5-nitro-, m.p. 222° (decomp.) [also from (VII) and  $\text{Br}\cdot\text{AcOH}$  at 100°], and 5-nitro-8-hydroxy-1-ethyl-2:3-dihydropyriminazole. J. W. B.

$\alpha\beta$ -Naphthoquinoxaline-2:3-dicarboxylic acid. G. B. CRIPA and G. PERRONCITO (Annali Chim. Appl., 1935, 25, 618–620).—1-Benzeneazo- $\beta$ -naphthylamine condenses with  $\text{CO}_2\text{Et}\cdot\text{CH}_2\cdot\text{CO}\cdot\text{CO}_2\text{Et}$  at 190° to form *Et*,  $\alpha\beta$ -naphthoquinoxaline-2:3-dicarboxylate (I), m.p. 119°, and a substance, m.p. 205–210°. (I) is hydrolysed to the dicarboxylic acid, m.p. 195° (decomp.) (anhydride, m.p. 235°). E. W. W.

**Pyrrole-blues. III.** P. PRATESI and A. ZANETTA (Atti R. Accad. Lincei, 1935, [vi], 22, 159–165).—Isatin (1 mol.) in AcOH with 2:3:4-trimethylpyrrole (1 mol.) yields 3-(3':4':5'-trimethyl-2'-pyrrolyl)oxindole. Oxidation of opsopyrrole-blue (A., 1935, 1134) with  $\text{H}_2\text{O}_2$  or  $\text{CrO}_3$  affords isatin and methyllethylmaleinimide; that of pyrrole-blue B (I) (A., 1905, i, 841; 1907, i, 657) gives maleinimide and isatin. Dry distillation of (I) in a vac. affords oxindole. The production of isatin-5-sulphonic acid indicates that the sulphonic acid of (I) (*ibid.*) is 3-(2'-pyrrolyl)oxindole-5-sulphonic acid. The constitution of the pyrrole-blues is discussed. F. O. H.

**Indoles and isatogens. XXI.** Condensation of the three phthalaldehydes with nitrated tolu-

enes and preparation of di-isatogens. P. RUGGLI and E. WOLFF (Helv. Chim. Acta, 1936, 19, 5–15).— $p\text{-C}_6\text{H}_4(\text{CHO})_2$  and 2:4- $\text{C}_6\text{H}_3\text{Me}(\text{NO}_2)_2$  in presence of piperidine at 160° give 2:4:2':4'-tetranitro-*p*-distyrylbenzene, m.p. 294°, transformed by  $\text{Cl}_2$  in AcOH at 110° into the corresponding tetrachloride, m.p. (indef.) 92–99°, which passes in boiling  $\text{C}_5\text{H}_5\text{N}$  into 2:4:2':4'-tetranitro-*p*-dichlorostyrylbenzene (I), m.p. 248°. Protracted insolation of (I) suspended in  $\text{C}_5\text{H}_5\text{N}$  yields 6:6'-dinitro-2:2'-*p*-phenylenedi-isatogen,  $p\text{-C}_6\text{H}_4(\text{C} \begin{smallmatrix} \text{CO} \\ \text{NO} \end{smallmatrix} \text{C}_6\text{H}_3\cdot\text{NO}_2)_2$ , m.p. 294°, reduced by  $\text{NHPh}\cdot\text{NH}_2$  in EtOH at 100° to dinitro-*p*-phenylenedi-indoxyl, isolated as the *Ac*, derivative, gradual decomp. > 280°. Similarly,  $m\text{-C}_6\text{H}_4(\text{CHO})_2$  gives 2:4:2':4'-tetranitro-*m*-distyrylbenzene, m.p. 243°, the tetrachloride, m.p. (indef.) 90–108°, of which gives 2:4:2':4'-tetranitro-*m*-dichlorostyrylbenzene, m.p. 215°, whence 6:6'-dinitro-2:2'-*m*-phenylenedi-isatogen, m.p. 289° (decomp.), reduced to dinitro-*m*-phenylenedi-indoxyl (*Ac*, derivative, m.p. 304°). Under like conditions *o*- $\text{C}_6\text{H}_4(\text{CHO})_2$  undergoes one-sided condensation giving *o*-2':4'-dinitrostyrylbenzaldehyde, m.p. 186° (phenylhydrazone, m.p. 193°).  $p\text{-C}_6\text{H}_4(\text{CHO})_2$  and *o*-nitro-*p*-toluonitrile give 2:2'-dinitro-4:4'-dicyano-*p*-distyrylbenzene, m.p. 350° (decomp.), whence the corresponding tetrachloride, m.p. 218°, 2:2'-dinitro-4:4'-dicyano-*p*-dichlorostyrylbenzene, m.p. 296°, and (?) 6:6'-dicyano-2:2'-*p*-phenylenedi-isatogen, blackens > 300°. 2:2'-Dinitro-4:4'-dicyano-*m*-distyrylbenzene, m.p. 298°, gives a tetrachloride, m.p. (indef.) 80–100°, or cryst. m.p., 248°, and thence 2:2'-dinitro-4:4'-dicyano-*m*-dichlorostyrylbenzene, m.p. 268°, and 6:6'-dicyano-2:2'-*m*-phenylenedi-isatogen, decomp. about 300° after darkening at 270°. *o*-2'-Nitro-4'-cyanostyrylbenzaldehyde, m.p. 210°, and its phenylhydrazone, m.p. 182°, are described. H. W.

**Quaternary ammonium compounds of derivatives of the anthracene series** [mainly pyrimidines].—See B., 1936, 140.

**Absorption spectra of 1:2:3-benzotriazoles.** A. K. MACBETH and J. R. PRICE (J.C.S., 1936, 111–119).—1:2:3-Benzotriazole and its derivatives absorb in two main regions, the shorter-wave region being attributed to an electron in the C:C system of the  $\text{C}_6\text{H}_6$  nucleus, and the other being assigned to the N:N of the triazole ring. Introduction of alkyl substituents into the nucleus results in improved separation of the two regions. No absorption characteristic of  $\text{NO}_2$  is observed unless an aq. solvent is used or OMe or OH is present in the triazole ring. 1-Hydroxy-1:2:3-benzotriazole and its 6-Me derivative exist in EtOH as equilibrium mixtures of two tautomeric forms, whilst  $\text{NO}_2\cdot\text{OH}$ -compounds exist as the stable OH-form in EtOH and aq. solution. Displacements of the max. are found, on change of solvent from EtOH to  $\text{H}_2\text{O}$ , in the  $\text{NO}_2\cdot\text{OH}$ -compound. 3-Nitro-4-chlorotoluene with  $\text{N}_2\text{H}_4$  gives 1-hydroxy-6-methyl-1:2:3-benzotriazole, m.p. 178–179°.

F. R. S.

**New soluble derivative of caffeine.** G. BARGIONI (Boll. Chim. farm., 1935, 74, 869–871).—Bromocaffeine and  $\text{CHNa}(\text{CO}_2\text{Et})_2$  give *Et*, caffeine-

malonate, converted into the acid, and into *caffeine-acetic acid*, of which the very sol. *Na* salt has the pharmacological character of caffeine, without toxicity. E. W. W.

**A new heterocyclic grouping: benzopyrimidazole.** C. B. CRIPPA and G. PERRONCITO (Gazzetta, 1935, 65, 1067—1070).—2-Aminobenziminazole and

$\text{CH}_2\text{Ac}\cdot\text{CO}_2\text{Et}$  give 2-methyl-3:4-dihydrobenzopyrimidazol-4-one (I), m.p.  $280^\circ$ , converted by boiling 25%  $\text{NaOH}$  into  $\beta$ -2-benziminazolyl-iminobutyric or -aminocrotonic acid, m.p.  $> 300^\circ$ . With

$\text{Br}$  in  $\text{AcOH}$  (I) forms a 3:3- $\text{Br}_2$ -derivative, m.p.  $> 300^\circ$ . E. W. W.

**Stereochemistry of tervalent nitrogen.** J. KENNER and F. S. STATHAM (Ber., 1936, 69, [B], 187—188).—The *brucine*, m.p.  $240\text{--}244^\circ$ ,  $[\alpha]_D^{18} +1.113^\circ$  in  $\text{CHCl}_3$ , *quinine*, m.p.  $205\text{--}210^\circ$ ,  $[\alpha]_D^{17} -145.2^\circ$  in  $\text{AcOH}$ , *strychnine*, m.p.  $220\text{--}224^\circ$ ,  $[\alpha]_D^{17} -1.559^\circ$  in  $\text{CHCl}_3$  and *cinchonine*, m.p.  $220^\circ$ ,  $[\alpha]_D^{15} +144.0^\circ$  in  $10N\text{-AcOH}$ , salts of benzotetrazolecarboxylic acid (I)

and the *brucine*, m.p.  $218^\circ$ ,  $[\alpha]_D^{20} -18.71^\circ$  in  $10N\text{-AcOH}$ , and *quinine*, m.p.  $135\text{--}145^\circ$ ,  $[\alpha]_D^{17.5} -161.6^\circ$  in  $\text{AcOH}$ , salts of benzotriazolecarboxylic acid (II) give no indication (I) of the possible resolution of (I) and (II) into optical antipodes; a plane configuration of this type of compound of  $\text{N}^{III}$  is therefore regarded as established experimentally. H. W.

**Chlorophyll. LXV. Synthesis of oxorhodophorphyrin, its conversion into 1:3:5:8-tetramethyl-4-ethyl-2-hydroxyethylporphin-6-carboxylic acid-7-propionic acid; pseudoverdoporphyrin.** H. FISCHER and G. KRAUSS (Annalen, 1936, 521, 261—285).—Oxorhodophorphyrin  $\text{Me}_2$  ester (I) ( $A$ ,  $R=\text{Ac}$ ) (A, 1934, 420; improved prep.) (semicarbazone, decomp.  $270^\circ$ ; *hæmin*, decomp.  $287^\circ$ ) with cold  $\text{Br}\cdot\text{HCO}_2\text{H}$  affords (by replacement of 2-Ac by  $\text{Br}$ ) the 2-*Br*-derivative (II), m.p.  $300^\circ$  ( $\text{Cu}$  complex salt, m.p.  $268^\circ$ , decomp.  $278^\circ$ ), of 2-*de*-ethyl-rhodophorphyrin (III), m.p.  $230\text{--}232^\circ$ , which is obtained either by the resorcinol fusion of the *hæmin* of (II) (together with 2-*de*-ethylpyrroporphyrin) or, better, by  $\text{KOH}\cdot\text{MeOH}$  hydrolysis of (II) and reduction with  $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}\cdot\text{Pd}\cdot\text{CaCO}_3$ . Reacetylation of the *hæmin* ester of (III) with  $\text{Ac}_2\text{O}\cdot\text{SnCl}_4$  and re-esterification of the product with  $\text{CH}_3\text{N}_2$  gives [2-*de*-ethyl-2-acetyl-rhodophorphyrin  $\text{Me}_2$  ester identical with (I), and reduced by  $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}\cdot 3\%$   $\text{NaOMe}$  to rhodophorphyrin (IV). In agreement with the structure assigned oxidation of (I) with  $\text{PbO}_2\cdot\text{H}_2\text{SO}_4$  at  $0^\circ$  gives methylethylmaleimide. 2-Hydroxyethylrhodophorphyrin (V), m.p.  $255^\circ$  (*loc. cit.*; by  $\text{MeOH}\cdot\text{KOH}$  reduction of the 2-Ac compound) ( $\text{Cu}$  complex salt, m.p.  $222^\circ$ ), is reduced by  $\text{AcOH}\cdot\text{HI}$  (*d* 1.96) to (IV), and is reoxidised by cold 20% oleum-S to the 2-Ac derivative. With  $\text{HBr}\cdot\text{AcOH}$  at  $45^\circ$  and treatment of the product with  $\text{KOH}\cdot\text{MeOH}$ ,  $\text{AcOH}$ , and  $\text{CH}_2\text{N}_2$

(V) gives a porphyrin with 3-OMe (partial ether formation), which does not depress the m.p. of (V),

and could not be converted into the 2-vinyl derivative by heating with  $\text{Cu}$  powder in quinoline. The *hæmin* ester of (III) with  $\text{CHCl}_3\cdot\text{OEt}\cdot\text{POCl}_3\cdot\text{SnCl}_4$  (cf. A., 1934, 1234) and subsequent re-esterification gives [2-*de*-ethyl-2-formylrhodophorphyrin ester, m.p.  $283^\circ$  (VI) (*oxime*, m.p.  $262^\circ$ ), converted by  $\text{MgMeI}$  in  $\text{C}_6\text{H}_5\text{N}\cdot\text{Et}_2\text{O}$  into [2-*de*-vinyl-2-hydroxyethylpseudoverdoporphyrin (VII), m.p.  $250^\circ$ . Treatment of the  $\text{HBr}\cdot\text{AcOH}$  rearrangement product of pseudoverdoporphyrin  $\text{Me}_2$  ester with  $\text{KOME}\cdot\text{MeOH}$  gives [2-*de*-vinyl-2-methoxyethylpseudoverdoporphyrin ester, m.p.  $196^\circ$ , not identical with (VII), but with 20% aq.  $\text{KOH}$  the  $\text{Me}_2$  ester, m.p.  $252^\circ$ , of (VII) is obtained. Pseudoverdoporphyrin (VIII) ( $A$ ;  $R=\text{CH}\cdot\text{CH}_2$ ) therefore contains a vinyl group and its  $\text{Me}_2$  ester with  $\text{Br}\cdot\text{HCO}_2\text{H}$  followed by  $\text{MeOH}\cdot\text{KOH}$  gives a *Br*-derivative,  $\text{C}_{37}\text{H}_{46}\text{O}_6\text{N}_4\text{Br}$ , m.p.  $190^\circ$  [side-chain  $\cdot\text{CHBr}\cdot\text{CH}_2\cdot\text{OMe}$  or  $\cdot\text{CH}(\text{OMe})\cdot\text{CH}_2\text{Br}$ ].  $\text{CHN}_2\cdot\text{CO}_2\text{Me}$  the  $\text{Me}_2$  ester of (VIII) gives the compound  $\text{C}_{37}\text{H}_{46}\text{O}_6\text{N}_4$  (IX), m.p.  $247^\circ$ , and with  $\text{PhN}_3$  it is converted into (VI). Phætopurpurin 7 (X) must also contain a  $\cdot\text{CH}\cdot\text{CH}_2$  group and its  $\text{Me}_2$  ester reacts with  $\text{CHN}_2\cdot\text{CO}_2\text{Me}$  to give a liquid product, converted by  $\text{C}_6\text{H}_5\text{N}\cdot\text{MeOH}$  into (IX). (X) has, therefore, structure B ( $R=\text{CH}\cdot\text{CH}_2$ ). With  $\text{AcOH}\cdot\text{HI}$  (XI) and purpurin 18 give a mixture of (IV) and its  $\gamma$ -carboxylic acid, and chlorin  $p_6$  gives only the latter product. J. W. B.

**Optical activity of horse's globin-hæmochromogen and of hæmoglobin.**—See this vol., 221.

**Porphyrin-gelatin phosphorescence.** F. DOW and E. J. KLAUS (Z. physiol. Chem., 1936, 238, 1—13).—The absorption and fluorescence spectra of porphyrins in gelatin films closely resemble the absorption spectra of solutions. The fluorescence spectra are less intense and the max. are shifted slightly towards the red.  $p_H$  has great influence, and is changed by buffering or by variation of the solvent used for the porphyrin. No chemical or physical change occurs during prep. of the films. R. S. A.

**Constitution of stercobilin.** H. FISCHER and H. HALBACH (Z. physiol. Chem., 1936, 238, 59—Stereobilin (I) (modified prep.),  $\text{C}_{33}\text{H}_{46}\text{O}_6\text{N}_4$ , m.p. -

readily absorbs 2H in AcOH (Pd-black), but 4H in 0.05*N*-NaOH; it cannot be converted into or obtained from mesobilirubinogen (II). (II) with O<sub>2</sub> in HCl gives mesobiliviolin and a little urobilin [reduced to (II) by Na-Hg]. (I) and HNO<sub>3</sub> give (·CH<sub>2</sub>-CO<sub>2</sub>H)<sub>2</sub>, but no methylethylmaleinimide which is readily so obtained from mesobilirubin (III) or glaucobilin (IV). (I) and HI-AcOH at 100° give pyrrole bases but no bilirubinic acid. With HBr-AcOH at 180° (I) gives an unidentified porphyrin. With PhN<sub>3</sub>Cl (II) and (III) give the ester *hydrochloride*, m.p. 193°, of a dye, *stercobilinogen* gives an uncrystallisable dye, but (I) does not react; (I) also does not react with PhCHO. With conc. H<sub>2</sub>SO<sub>4</sub> at 100° (I), (II), and (III) give (IV). (I) is strongly levorotatory (hydrochloride, [ $\alpha$ ]<sub>D<sup>20</sup></sub><sup>0.550</sup> -1733°, [ $\alpha$ ]<sub>D<sup>20</sup></sub><sup>0.550</sup> -1007° in AcOH), but is readily racemised by various reagents. (I) is probably as shown. Opsopyrrole and *p*-C<sub>6</sub>H<sub>4</sub>Me-N<sub>2</sub>Cl give a monazo-dye, m.p. 238° (*hydrochloride*, m.p. 208°; *hydrobromide*, m.p. 185°; *picrate*, m.p. 182°).

R. S. C.

Preparation and tinctorial properties of benzoxazole dyes. V. J. MIKESKA and M. T. BOGERT (J. Amer. Chem. Soc., 1935, 57, 2513—2517).—A series of substantive cotton dyes are prepared from diazotised 4-phenyl-1-*p*-aminophenylbenzoxazole (I) [and its  $\text{SO}_3\text{H}$  derivative (II)] and 4-amino-1 : 6-diphenylbenzoxazole (III) (and its  $\text{SO}_3\text{H}$  derivative) by coupling with  $\alpha$ - and  $\beta$ - $\text{C}_{10}\text{H}_7\cdot\text{OH}$ ,  $\text{PhOH}$ ,  $m\text{-C}_6\text{H}_4(\text{OH})_2$ , and  $\alpha\text{-C}_{10}\text{H}_7\cdot\text{NH}_2$ ; those prepared from (I) are more substantive than those from (III). The dyes resemble, but give lighter shades than, the corresponding derivatives from dehydrothio-*p*-toluidine (1.) (A., 1927, 679). Absorption curves for "ingrain red" [from (IV) and  $\beta\text{-C}_{10}\text{H}_7\cdot\text{OH}$ ] and "oxazole red" [from (II) and  $\beta\text{-C}_{10}\text{H}_7\cdot\text{OH}$ ] are given; the former shows wider absorption. Oxidation (aq.  $\text{EtOH-NaOCl}$  at  $0-10^\circ$ ) of (I) gives  $\text{pp}'$ -di-(4-phenyl-1-benzoxazolyl)azobenzene, decomp.  $>300^\circ$  [ $(\text{SO}_3\text{Na})_2$  derivative (V);  $(\text{SO}_3\text{Na})_4$  derivative, prepared by similar oxidation of 4-phenyl-1-*p*-aminophenylbenzoxazolesulphonic acid]. Similar "chloramine yellow" dyes are prepared from 1-*p*-aminophenyl-4-methylbenzoxazole [resembles (V)] and (III) [inferior to (V)]. Fabrics dyed directly retain (after 5 years) a better colour than those dyed by the "ingrain" process.

Н. 1

Pyridine and quinoline derivatives of dibenzfuran and their physiological properties. W. H. KIRKPATRICK and H. GILMAN (Proc. Iowa Acad. Sci., 1934, 41, 172).—The physiological properties of a no. of amino- and substituted amino-dibenzfurans and their amino reduction products have been studied. In many cases the  $\text{NH}_2$ -compounds undergo cyclisation, yielding pyridinodibenzfurans. CH. ABS. (r)

Alkyl derivatives of aryl-substituted thiazolones. J. A. DAVIS and F. B. DAINS (J. Amer.

Chem. Soc. 1935, 57, 2627—2630; cf. A., 1933, 1174).—Alkylation (alkyl halide on Na salt in EtOH) of 2-arylamino-4-thiazolidones [prepared (a) from  $\text{NHAr}\cdot\text{CO}\cdot\text{CH}_2\text{Cl}$  and KCNS in EtOH, or (b) from  $\text{NHAr}\cdot\text{CS}\cdot\text{NH}_2$  and equimol. amounts of  $\text{CH}_2\text{Cl}\cdot\text{CO}_2\text{Et}$  and  $\text{C}_5\text{H}_5\text{N}$  in EtOH] gives generally a mixture of a little 2-arylimino-3-alkyl-4-thiazolidone (I) [the 5-benzylidene derivatives of which are hydrolysed (EtOH—conc. HCl) to  $\text{NH}_2\text{Ar}$  and 2:4-diketo-5-benzylidene-3-alkyltetrahydrothiazoles] and much 2-N-alkylarylamino-4-thiazolidone (II) (the 5-benzylidene derivatives are hydrolysed to  $\text{NHArAlk}$  and 2:4-diketo-5-benzylidenetetrahydrothiazoles). Certain exceptions are noted. (I) are also synthesised from  $\text{CH}_2\text{Cl}\cdot\text{CO}_2\text{Et}$  and  $\text{NHAr}\cdot\text{CS}\cdot\text{NHalk}$ . The 3-aryl-2-ethylimino-4-thiazolidones of Beckurts and Frerich (A., 1916, i, 744) are (II). The following are described: (a) substituted thiocarbamides: *p*-cymyl-, m.p. 152°; *N*-o-, m.p. 88°, and -*p*-, m.p. 112°, -ethoxyphenyl-, *N*-*ψ*-cumyl-, m.p. 138°; *N*-o-, m.p. 77°, -*m*-, m.p. 112°, and -*p*-, m.p. 147°, -anisyl-, *N*-*p*-cymyl-, m.p. 126°, *N*-*p*-iodophenyl-, m.p. 147·5°, and *N*-2:4-di-iodophenyl-, m.p. 164°, -*N'*-ethyl-, *N*-*ψ*-cumyl-, m.p. 179°, and *N*-*p*-iodophenyl-, m.p. 171°, -*N'*-methyl-, *N*-*p*-iodophenyl-*N'*-amyl-, m.p. 130°, and -*N'*-benzyl-, m.p. 149°; (b) substituted 4-thiazolidones: 2-*p*-ethoxyanilo-3-ethyl-, m.p. 93° (5-benzylidene derivative, m.p. 135°); 2-*o*-ethoxyanilino-, m.p. 172°; 5-benzylidene derivative, m.p. 210°, of 2-*N*-ethyl-*p*-ethoxyanilino-; 2-*N*-ethyl-*o*-ethoxyanilino-, m.p. 99° (5-benzylidene derivative, m.p. 164°); 2-*o*-ethoxyanilo-3-ethyl-, m.p. 79° (5-benzylidene derivative, m.p. 113°); 2-*ψ*-cumylimino-3-methyl-, m.p. 91° (5-benzylidene derivative, m.p. 136°), and -3-ethyl-, m.p. 77° (5-benzylidene derivative, m.p. 141°); 5-benzylidene derivative, m.p. 180°, of 2-*N*-ethyl-*ψ*-cumylamino-; 2-*o*-, m.p. 114°, -*m*-, m.p. 65—66°, and -*p*-, m.p. 83°, -anisylimino-3-ethyl- (5-benzylidene derivatives, m.p. 99°, 109°, and 125°, respectively); the 5-benzylidene derivatives, m.p. 149°, 135°, and 198°, of 2-*N*-ethyl-*o*-, -*m*-, m.p. 112°, and -*p*-anisidino-, respectively; 2-*m*-anisidino-, m.p. 165°; 2-*p*-cymylamino-, m.p. 174°; 2-*N*-ethyl-*p*-cymylamino-, m.p. 85° (5-benzylidene derivative, m.p. 169°); 2-*p*-cymylimino-3-ethyl-, m.p. 64° (5-benzylidene derivative, m.p. 73°); 2-2':4'-di-iodoanilino-, m.p. 233°; 2-2':4'-di-iodoanilo-3-ethyl-, m.p. 173° (5-benzylidene derivative, m.p. 210—211°); 2-*p*-iodoanilino-, m.p. 226°; 2-*N*-methyl-, m.p. 207°, -ethyl-, m.p. 116°, -amyl-, m.p. 116°, and -benzyl-, m.p. 176°, -*p*-iodoanilino- (5-benzylidene derivatives, m.p. 246°, 231°, 202°, and 221°, respectively); 2-*p*-iodoanilo-3-methyl-, m.p. 152°, -ethyl-, m.p. 103°, -amyl-, m.p. 57°, and -benzyl-, m.p. 137° (5-benzylidene derivatives, m.p. 167°, 172°, 105°, and 162°, respectively); 2-anilino-3-amyl-, an oil (5-benzylidene derivative, m.p. 78°); 2-benzylimino-3-benzyl-, m.p. 74° (5-benzylidene derivative, m.p. 109°); (c) miscellaneous: chloroacet-2-*p*-cymidide, m.p. 85°, and -2:4-di-iodoanilide, m.p. 153°; *p*-nitrobenz-*o*-phenetidide, m.p. 155°; benzenesulphon-*N*-ethyl-*o*-phenetidide, m.p. 61°, -*N*-ethyl-*o*-anisidide, m.p. 90°, and -*N*-methyl-*p*-iodoanilide, m.p. 78°; *N'*-phenyl-*N*-*p*-ethoxyphenyl-*N*-ethyl-, m.p. 93°, and *N*-*p*-tolyl-*N'*-*o*-ethoxyphenyl-, m.p. 172°, -carbamides; 2:4-diketo-5-benzylidene-3-amyl-, m.p. 74°, and -3-benzyl-, m.p. 134°, -tetrahydrothiazoles.

H. B.

**Aneurine. II. Synthesis of N-arylthiazolium salts; details in the constitution of aneurine and thiochrome.** A. R. TODD, F. BERGEL, and KARIMULLAH (Ber., 1936, 69, [B], 217—223).— $\text{CH}_2\text{PhBr}$  and 2:4-dimethylthiazole at  $100^\circ$  give 3-benzyl-2:4-dimethylthiazolium bromide, m.p.  $173^\circ$ . Addition of thioacetmethylamide to  $\text{CH}_2\text{Cl}\cdot\text{COMe}$  at  $80^\circ$  yields 2:3:4-trimethylthiazolium chloride, m.p.  $235^\circ$  (decomp.). Similarly thioacetanilide and  $\text{CH}_2\text{Cl}\cdot\text{COMe}$  at  $100^\circ$  afford 3-phenyl-2:4-dimethylthiazolium chloride (I), m.p.  $184^\circ$  (decomp. in sealed capillary; corresponding picrate, m.p.  $115^\circ$ ). If reaction is effected at  $15\text{--}20^\circ$ , S-acetylthioacetanilide hydrochloride (II), m.p.  $112^\circ$  [corresponding perchlorate, m.p.  $130^\circ$ , unstable free base and its semicarbazone, m.p.  $230^\circ$  (decomp.)], is formed. It passes at  $100^\circ$  into (I) and is hydrolysed by boiling  $\text{H}_2\text{O}$  or dil. acid to  $\text{NH}_3\text{Ph}$ ,  $\text{NHAcPh}$ , and a substance (III), (?)  $\text{SH}\cdot\text{CH}_2\cdot\text{C}(\text{CH}_3)_2\cdot\text{S}\cdot\text{CH}_2\cdot\text{COMe}$  [semicarbazone,  $\text{C}_7\text{H}_{13}\text{ON}_3\text{S}_2$ , m.p.  $213^\circ$  (decomp.)]. 3-o-Tolyl-2:4-dimethylthiazolium chloride, perchlorate, m.p.  $172^\circ$ , picrate, m.p.  $150^\circ$ , and iodide, m.p.  $217\text{--}218^\circ$  (decomp.), are obtained analogously. S-Acetylthioacet-o-toluidide hydrochloride, m.p.  $125^\circ$ , is more stable than (II); its hydrolysis leads to  $\text{o-C}_6\text{H}_4\text{Me}\cdot\text{NH}_2$ ,  $\text{C}_6\text{H}_4\text{Me}\cdot\text{NHAc}$ , and (III).  $\text{o-NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{NHAc}$  is converted by cautious treatment with  $\text{P}_2\text{S}_5$  into o-nitrothioacetanilide, m.p.  $114^\circ$ , whence 3-o-nitrophenyl-2:4-dimethylthiazolium perchlorate, m.p.  $205^\circ$ . Determination of C-alkyl by oxidation with  $\text{CrO}_3$  of thiazolium, pyrimidine, and allied compounds shows that Williams' pyrimidine compound from aneurine (IV) contains only one alkyl; (IV) and thiochrome

each contains two alkyls, the higher val. indicated (Kuhn) for (IV) being observed with other compounds which lose CMe quantitatively.  $\text{o-C}_6\text{H}_3(\text{NH}_2)_2$  and  $\text{CS}(\text{NH}_2)_2$  yield thiobenziminazoline, m.p.  $295\text{--}300^\circ$ , converted by  $\text{CH}_2\text{Cl}\cdot\text{COMe}$  into 3-methylthiazolo-2':3':2:1-glyoxaline (V), m.p.  $164\text{--}165^\circ$ .

H. W.

**1-Amino-5-ethoxy-2-methylbenzthiazolium hydroxide and its derivatives.** O. BEHAGHEL and E. SCHNEIDER (Ber., 1936, 69, [B], 88—98).—Repetition of the work of Hunter *et al.* (A., 1930, 1452) shows that *p*-ethoxyphenylthiocarbamide is transformed by an excess of Br in  $\text{CHCl}_3$  into bromo-1-amino-5-ethoxybenzthiazole (I), m.p.  $196^\circ$ , and by the calc. quantity into 1-amino-5-ethoxybenzthiazole, m.p.  $162^\circ$ . Treatment of (I) with  $\text{Me}_2\text{SO}_4$  yields the corresponding methosulphate, converted by NaOH into bromo-1-imino-5-ethoxy-2-methylbenzthiazoline, m.p.  $144^\circ$ , also derived from *as-p*-ethoxyphenylmethylthiocarbamide, m.p.  $139^\circ$  (prepared from *N*-methyl-*p*-phenetidine hydrochloride and  $\text{NH}_4\text{CNS}$ ), and Br in  $\text{CHCl}_3$ . *N*-Methyl-*p*-phenetidine and KCNS in 95% AcOH are transformed by Br in warm AcOH into 1-amino-5-ethoxy-2-methylbenzthiazolium bromide, decomp.  $295^\circ$ , whereas in MeOAc the corresponding thiocyanate, m.p.  $187^\circ$ , is produced. Treatment of the salts with cold  $\text{Na}_2\text{CO}_3$  affords 1-amino-5-ethoxy-2-methylbenzthiazolium hydroxide (II), m.p. about  $64^\circ$ , which readily loses  $\text{H}_2\text{O}$  when kept over  $\text{H}_2\text{SO}_4$

giving 1-imino-5-ethoxy-2-methylbenzthiazoline (III), m.p.  $98^\circ$ . 1-Amino-5-ethoxybenzthiazole (III) is transformed by  $\text{Me}_2\text{SO}_4$  at  $100^\circ$  into 1-amino-5-ethoxy-2-methylbenzthiazolium methosulphate, m.p.  $187\text{--}189^\circ$ , converted by NaOH into 1-methylimino-5-ethoxy-2-methylbenzthiazoline, m.p.  $86^\circ$ . 1-Amino-5-ethoxy-2-methylbenzthiazolium iodide, m.p.  $245^\circ$ , results from (II) and HI or from (IV) and MeI in MeOH at  $100^\circ$ , whilst the corresponding chloride, m.p.  $308^\circ$  (decomp.), is obtained from (II) and boiling HCl. The presence of NH in (III) is established by the isolation of 1-nitrosoimino-5-ethoxy-2-methylbenzthiazoline, which evolves  $\text{N}_2$  quantitatively when boiled with xylene and gives 5-ethoxy-2-methylbenzthiazolone, m.p.  $87^\circ$ . (III) is converted by boiling  $\text{Ac}_2\text{O}$ , BzCl, or valeric anhydride, respectively, into 1-acetimido-, m.p.  $172^\circ$ , 1-benzimido-, m.p.  $191^\circ$ , and 1-valerimido-, m.p.  $119^\circ$ , -5-ethoxy-2-methylbenzthiazoline, which essentially yield salts with mineral acids. Bromo-1-amino-5-ethoxy-2-methylbenzthiazolium methosulphate is transformed by  $\text{Me}_2\text{SO}_4$  and NaOH into bromo-1-methylimino-5-ethoxy-2-methylbenzthiazoline, m.p.  $158^\circ$ , transformed by  $\text{NaNO}_2$  in AcOH and subsequent treatment of the product with boiling xylene into bromo-5-ethoxy-2-methylbenzthiazolone, m.p.  $126^\circ$ . The benzthiazolium hydroxides and benzthiazolines have identical absorption spectra in MeOH possibly owing to conversion of the former into the latter. The absorption spectra of 2-methylated benzthiazole, benzoxazole, benz-selenazole, and benziminazole are compared. *p*-Chlorophenyl-thiolacetic and -selenolacetic acid have closely similar absorption spectra which differ considerably from that of *p*-chlorophenoxyacetic acid.

H. W.

**Compounds for treatment of textiles [benzthiazoles].**—See B., 1936, 92.

**Cyanine dye series. II. Carbocyanines with substituents in the three-carbon chain.** L. G. S. BROOKER and F. L. WHITE (J. Amer. Chem. Soc., 1935, 57, 2480—2488).—Substituted thiocarbocyanine iodides,  $\text{C}_6\text{H}_4\text{--}\langle\text{S--NR}\rangle\text{--C}\cdot\text{CH}\cdot\text{CR}'\cdot\text{CH}\cdot\text{C}\langle\text{S--NRI}\rangle\text{--C}_6\text{H}_4$ ,

are prepared from various ortho-esters (I), *e.g.*,  $\text{CR}'(\text{OMe})_3$  ( $\text{R}'=\text{H}$ , Me, Et, Pr, Bu, amyl,  $\text{CH}_2\text{Ph}$ ,  $\text{OPh}\cdot\text{CH}_2$ , Ph) and 1-methylbenzthiazole alkiodides or alk-*p*-toluenesulphonates (followed by aq. KI) in boiling  $\text{C}_5\text{H}_5\text{N}$ . The following are described: 2:2'-diallyl-, m.p.  $264\text{--}266^\circ$  (decomp.); 2:2'-di-*n*-propyl-, m.p.  $296\text{--}297^\circ$  (decomp.); 2:2'-di-*n*-butyl-, m.p.  $275\text{--}277^\circ$  (decomp.); 8-methyl-2:2'-diallyl-, m.p.  $267\text{--}268^\circ$  (decomp.), -2:2'-di-*n*-propyl-, m.p.  $295\text{--}296^\circ$  (decomp.), and -2:2'-di-*n*-butyl-, m.p.  $236\text{--}237^\circ$  (decomp.); 2:2'-dimethyl-8-ethyl-, m.p.  $286\text{--}287^\circ$  (decomp.); 2:8:2'-triethyl-, m.p.  $236\text{--}237^\circ$  (decomp.); 8-ethyl-2:2'-diallyl-, m.p.  $214\text{--}216^\circ$  (decomp.), -2:2'-di-*n*-propyl-, m.p.  $248\text{--}250^\circ$  (decomp.), and -2:2'-di-*n*-butyl-, m.p.  $241\text{--}243^\circ$  (decomp.); 2:2'-dimethyl-8-*n*-propyl-, m.p.  $268\text{--}269^\circ$  (decomp.), -8-*n*-butyl-, m.p.  $168\text{--}169^\circ$  (decomp.), -8-*n*-amyl-, m.p.  $217\text{--}219^\circ$  (decomp.), -8-isoamyl-, m.p.  $241\text{--}242^\circ$  (decomp.), -8-benzyl-, m.p.  $288\text{--}289^\circ$  (decomp.), -8-phenoxyethyl- (bromide), m.p.  $255\text{--}257^\circ$  (decomp.), and -8-phenyl-, m.p.  $275\text{--}277^\circ$  (decomp.); 2:2'-diethyl-8-*n*-propyl-, m.p.  $246\text{--}$

248° (decomp.), -8-*n*-butyl-, m.p. 233—234° (decomp.), -8-*n*-amyl-, m.p. 237—238° (decomp.), -8-isoamyl-, m.p. 219—220° (decomp.), -8-benzyl-, m.p. 242—243° (decomp.), -8-phenoxymethyl-, m.p. 202—204° (decomp.), and -8-phenyl-, m.p. 300—301° (decomp.); 8-benzyl-, m.p. 225—227° (decomp.), and 8-phenoxymethyl-, m.p. 211—213° (decomp.), -2:2'-diallyl-. In the above series introduction of 8-Me (for H) causes a shift in the absorption max. (in MeOH) of about 150 Å. towards the blue; replacement of 8-Me by Et (or higher alkyl) causes a shift of about 50 Å. back towards the red. The following substituted 5:6:5':6'-dibenzthiacarbocyanine bromides are similarly prepared from (I) and 1-methyl- $\alpha$ -naphthothiazole meth-*p*-toluenesulphonate, m.p. 232—233°, or etho-*p*-toluenesulphonate followed by aq. KBr: 2:2'-dimethyl-, m.p. 285° (decomp.); 2:2'-diethyl-, m.p. 280° (lit. 274°) (decomp.); 2:8:2'-trimethyl-, m.p. 278—281° (decomp.); 8-methyl-2:2'-diethyl-, m.p. 261° (decomp.); 2:2'-dimethyl-8-ethyl-, m.p. 299° (decomp.); 2:8:2'-triethyl-, m.p. 296° (decomp.); 8-phenyl-2:2'-dimethyl-, m.p. 308—310° (decomp.), and -2:2'-diethyl-, m.p. 296° (decomp.). 2:2'-Dimethyl-, m.p. 237° (decomp.), 2:8:2'-trimethyl-, m.p. 240—241° (decomp.), 2:2'-dimethyl-8-ethyl-, m.p. 230° (decomp.), 2:8:2'-triethyl-, m.p. 247° (decomp.), and 8-phenyl-2:2'-dimethyl-, m.p. 242—244° (decomp.), and -2:2'-diethyl-, m.p. 252° (decomp.), -3:4:3':4'-dibenzthiacarbocyanine bromides are similarly obtained from 2-methyl- $\beta$ -naphthothiazole meth-*p*-toluenesulphonate, m.p. 189—190°, or the etho-*p*-toluenesulphonate. 1-Methylbenzelenazole meth- and etho-*p*-toluenesulphonates lead to 2:8:2'-trimethylselenacarbocyanine bromide, m.p. 290—291° (decomp.), and 2:2'-dimethyl-8-ethyl-, m.p. 271—272° (decomp.), 2:8:2'-triethyl-, m.p. 146—148°, and 8-phenyl-2:2'-dimethyl-, m.p. 271—272° (decomp.), and -2:2'-diethyl-, m.p. 280—281° (decomp.), -selenacarbocyanine iodides. 2:8:2'-Trimethyl-, m.p. 290—292° (decomp.), 2:2'-dimethyl-8-ethyl-, m.p. 280—282° (decomp.), and 2:8:2'-triethyl-, m.p. 269—270° (decomp.), -oxacarbocyanine iodides, prepared from the appropriate benzoxazole salts and (I) in  $C_5H_5N$ -NEt<sub>3</sub>, are sensitizers for the green and blue-green. Absorption curves for many of the dyes are given. The following are new: *Me* ortho-propionate, b.p. 126—128°, -*n*-butyrate, b.p. 145—147°, -*n*-valerate, b.p. 167—170°, -*n*-hexoate, b.p. 187—190°, and -isohexanoate, b.p. 178—181°; *Et* ortho-phenoxyacetate, b.p. 99—100°/1.5 mm., and -benzoate, b.p. 239.5—240.5°; 1-methylbenzthiazole *n*-propyl iodide, m.p. 173—175°, -*n*-butyl iodide, m.p. 186—187°, allyl iodide, m.p. 192—193°, and meth-*p*-toluenesulphonate, m.p. 183.5—184.5°.

H. B.

**Cyanine dye series. III. Improvements in the 2'-cyanine condensation.** L. G. S. BROOKER and G. H. KEYES. IV. [Thiazolo-2'-cyanines and related compounds.] L. G. S. BROOKER, G. H. KEYES, and F. L. WHITE (J. Amer. Chem. Soc., 1935, 57, 2488—2492, 2492—2496).—III. 2:1'-Diethyl-oxa-2'-cyanine iodide (A, R=O), m.p. 290—292° (decomp.), obtained in 43—56% yield from 2-iodoquinoline ethiodide (I) and 1-methylbenzoxazole ethiodide in EtOH-NEt<sub>3</sub>, is best prepared using NPhEt<sub>2</sub> (at 100°)

as the condensing agent; EtOH-KOH (cf. Hamer, A., 1928, 307) leads to a 3% yield. The following are prepared in yields of 10—87% usually in Pr<sup>4</sup>OH-NEt<sub>3</sub>: 2:1'-diethylseleno-2'-cyanine iodide (A, R=Se), m.p. 280—282° (decomp.), from (I) and 1-methylbenzelenazole ethiodide; 1:1'-diethyl-2-pyridyl-2'-cyanine iodide (II), m.p. 237—239° (decomp.), from (I) and 2-methylpyridine ethiodide (III) or from 2-iodopyridine ethiodide (IV) and 2-methylquinoline ethiodide (thus affording further evidence of the virtual tautomerism of the cyanine dyes); 1:1'-diethyl-2-pyridyl-4'-cyanine iodide, m.p. 194—196° (decomp.), from (IV) and 4-methylquinoline ethiodide;

1:1'-diethyl-4-pyridyl-2'-cyanine perchlorate, m.p. 211—214° (decomp.), from (I) and 4-methylpyridine etho-*p*-toluenesulphonate (V) followed by aq. KClO<sub>4</sub>; 1:1'-dimethyl-2:2'-pyridocyanine iodide, m.p. 315—317° (decomp.), from 2-iodopyridine methiodide (VI) and 2-methylpyridine methiodide; 1:1'-diethyl-2:2'-pyridocyanine iodide (VII), m.p. 237—239° (decomp.), from (III) and (IV); 1:1'-dimethyl-2:4'-pyridocyanine iodide, m.p. 214—217° (decomp.), from (VI) and 4-methylpyridine meth-*p*-toluenesulphonate; 1:1'-diethyl-2:4'-pyridocyanine iodide, m.p. 163—166° (decomp.), from (IV) and (V). Absorption curves for the above dyes are given. All the compounds containing the  $C_5H_5N$  ring show sensitising action.

IV. 2-Methylthiazole ethiodide, m.p. 195—197°, and 2-iodoquinoline ethiodide (I) in EtOH-NEt<sub>3</sub> give 3:1'-diethylthiazolo-2'-cyanine iodide (B, R=S; R'=H), m.p. 267—269° (decomp.); the 4-Me, m.p. 255—257° (decomp.), and 4-Ph, m.p. 256—258° (decomp.),

derivatives of this are similarly formed from (I) and 2:4-dimethylthiazole ethiodide and 4-phenyl-2-methylthiazole ethiodide, m.p. 175.5—176.5°, respectively.

Similarly, (I) with 2:4-dimethyl- (II) and 4-phenyl-2-methyl-oxazole etho-*p*-toluenesulphonates affords 4-methyl- (B, R=O; R'=Me), m.p. 255—258° (decomp.), and 4-phenyl-, m.p. 262—264° (decomp.), -3:1'-diethyloxazolo-2'-cyanine iodide, respectively, whilst (I) and the ethiodide, m.p. 157—158°, of 2:4-dimethylselenazole, b.p. 54—55°/12 mm. [from selenoacetamide (modified prep.) and COMe·CH<sub>2</sub>Cl], give 4-methyl-3:1'-diethylselenazolo-2'-cyanine iodide (B, R=Se; R'=Me), m.p. 259—260° (decomp.). 2-Iodo- $\beta$ -naphthquinoline ethiodide and the above S, O, and Se salts [except (II)] afford 3:1'-diethyl-, m.p. 268—270° (decomp.), 4-methyl-3:1'-diethyl-, m.p. 278—280° (decomp.), and 4-phenyl-3:1'-diethyl-, m.p. 274—276° (decomp.), -5':6'-benzthiazolo-, 4-phenyl-3:1'-diethyl-5':6'-benzoxazolo-, m.p. 279—282° (decomp.), and 4-methyl-3:1'-diethyl-5':6'-benzelenazolo-, m.p. 275—277° (decomp.), -2'-cyanine iodides, respectively. 3:1'-Diethyl-, m.p. 260—262°

(decomp.), 4-methyl-3:1'-diethyl-, m.p. 255—257° (decomp.), and 4-phenyl-3:1'-diethyl-, m.p. 247—249° (decomp.), -thiazolo-, and 4-methyl-3:1'-diethylselenazolo-, m.p. 232—233° (decomp.), -2'-pyridocyanine iodides are prepared from 2-iodopyridine ethiodide and the above S and Se salts. All the above dyes are sensitizers; absorption spectra are given.

**Catalysed photo-reduction of vat dyes.**—See this vol., 300.

**Alkaloids from the seeds of *Cassia absus*, Linn.** S. SIDDIQUI and Z. AHMED (Proc. Indian Acad. Sci., 1935, 2, A, 421—425).—Kernels of these seeds extracted with MeOH-HCl give a product from which the quaternary alkaloids *chaksine* (I) and *iso-chaksine* (II) are separated through their iodides. *Chaksine iodide* (III), m.p. 168° (decomp.), is converted into the (impure) base,  $[\alpha]_D^{25} + 32^\circ$  in EtOH, which absorbs CO<sub>2</sub> from the air to give *chaksine H carbonate*, C<sub>12</sub>H<sub>20</sub>ON<sub>3</sub>·HCO<sub>3</sub>·0.5H<sub>2</sub>O, m.p. 167—169° (decomp.). *Chaksine sulphate* (IV), m.p. 316° (decomp.), and *picrate*, m.p. 239—240° (decomp.), are prepared; the *platinichloride*, (C<sub>12</sub>H<sub>20</sub>ON<sub>3</sub>·HCl)<sub>2</sub>PtCl<sub>6</sub>, m.p. 232° (decomp.), loses HCl at 120°. *isoChaksine iodide* gives (II); this is also obtained by treating (IV) with Ba(OH)<sub>2</sub>, and its *carbonate*, (C<sub>12</sub>H<sub>20</sub>ON<sub>3</sub>)<sub>2</sub>CO<sub>3</sub>, m.p. 128° (decomp.), by heating *chaksine H carbonate* in EtOH. *isoChaksine chloride* loses H<sub>2</sub>O at 90° to form a *product*, m.p. 250—252°; the *picrate* has m.p. 184°; the *platinichloride*, (C<sub>12</sub>H<sub>20</sub>ON<sub>3</sub>·HCl)<sub>2</sub>PtCl<sub>6</sub>, m.p. 172° (decomp.), is stable at 120°. (III) gives no evidence of containing OMe or N-Me; (I) and (II) appear to be quaternary bases, with a second N feebly basic. (IV) is a general depressant (heart, respiration, nerves); lethal dose for frogs, 0.1 g. per kg.

E. W. W.

**Alkaloid from *Crotalaria spectabilis*, Roth.** W. M. NEAL, L. L. RUSOFF, and C. F. AHMANN (J. Amer. Chem. Soc., 1935, 57, 2560—2561).—The seeds are soaked in 5% aq. NH<sub>3</sub> and the filtrate is extracted with CHCl<sub>3</sub>; *monocrotaline* (I), probably C<sub>16</sub>H<sub>26</sub>O<sub>6</sub>N, m.p. 196—197°, is thus obtained. (I) is the toxic principle of *C. spectabilis*; pharmacological data are given.

H. B.

**Alkaloid of *Stemona sessilifolia*.** H. SCHILD (Ber., 1936, 69, [B], 74—80).—The isolation from *S. sessilifolia* is described of an alkaloid (I), m.p. 86—87°, b.p. about 220°/0.0006 mm.,  $[\alpha]_D^{20} - 47.1^\circ$  in CHCl<sub>3</sub>, analyses of which together with those of its *perchlorate*, m.p. 243°, and *methiodide monohydrate* (II), decomp. 230—233°, agree most closely with the formula C<sub>22</sub>H<sub>33</sub>O<sub>2</sub>N. (II) is transformed by AgCl into the *methochloride dihydrate*, m.p. 169°, and by Ag<sub>2</sub>O into the *betaine*, C<sub>23</sub>H<sub>37</sub>O<sub>3</sub>N·H<sub>2</sub>O, decomp. 227—229°, which re-forms (II) when heated with HI. (I) is a *tert.* base which does not evolve CH<sub>4</sub> with MgMeI. 2 O are present in a lactone group, since it dissolves in 1 mol. of hot KOH. Further groups sensitive to alkali are not present. Catalytic hydrogenation of

(I) in neutral solution yields the *substance*, m.p. 118—120°,  $[\alpha]_D^{20} - 10.8^\circ$  in CHCl<sub>3</sub>, whereas in acid solution a *compound*, C<sub>22</sub>H<sub>35</sub>O<sub>4</sub>N, m.p. 134,  $[\alpha]_D^{20} - 13.2^\circ$  in CHCl<sub>3</sub> (*hydrochloride*), is produced. Since (I) does not give an ultra-violet absorption spectrum above 234—313 mμ the presence in it of an aromatic ring is excluded. The presence of a pyrrolidine ring is possible since in conjunction with I, MeI, or EtI it is oxidised by air to a neutral *substance*, C<sub>22</sub>H<sub>29</sub>O<sub>4</sub>N, m.p. 186°, which retains the lactone ring, readily gives the Ehrlich pyrrole reaction, and has a characteristic ultra-violet absorption spectrum. Electrolytic reduction of (I) yields the di-deoxo-base, C<sub>22</sub>H<sub>37</sub>O<sub>2</sub>N (*perchlorate*, m.p. 244—245°; *methiodide*, m.p. 261—262°), which does not contain a lactone group; the second replaced O is attributed to the presence of non-reactive CO. (I) is very stable towards HNO<sub>3</sub> and CrO<sub>3</sub> but is oxidised by KMnO<sub>4</sub>-H<sub>2</sub>SO<sub>4</sub> to *l*-methylsuccinic acid, m.p. 108—109°,  $[\alpha]_D^{20} - 9.3^\circ$  in CHCl<sub>3</sub>, and by alkaline KMnO<sub>4</sub> to a *substance*, C<sub>17</sub>H<sub>25</sub>O<sub>3</sub>N, m.p. 134—135° after softening at 130°.

H. W.

**Conessine series. I. Isomerisation of conessine and its nor-bases.** S. SIDDIQUI (Proc. Indian Acad. Sci., 1935, 2, A, 426—437; cf. A., 1934, 787).—Conessine dissolved in cold conc. H<sub>2</sub>SO<sub>4</sub>, poured on to ice, and treated with NaOH, AcOH, and KI, gives, with oxidation products, the *hydriodide*, m.p. 325—326° (decomp.), of *isoconessine* (I), C<sub>24</sub>H<sub>40</sub>N<sub>2</sub>, b.p. 239—241°/3 mm.,  $[\alpha]_D^{25} + 97^\circ$  in EtOH [*hydrochloride* (+2H<sub>2</sub>O), m.p. 318° (decomp.),  $[\alpha]_D^{25} + 72^\circ$ ; *platinichloride*, m.p. 271—273°; *aurichloride*, m.p. 293—295° (decomp.); *picrate*, m.p. 240—242° (decomp.); *hydrobromide* (II), m.p. 318—322° (decomp.); *dimethiodide*, m.p. 316—318° (decomp.)]. (I) with Br in CHCl<sub>3</sub> or AcOH yields (II) and an oily *product*. With H<sub>2</sub>SO<sub>4</sub>, *isoconessimine* similarly isomerises, to *isonorisconessimine* (III), C<sub>23</sub>H<sub>38</sub>N<sub>2</sub>,  $[\alpha]_D^{25} + 101^\circ$  in EtOH [*hydriodide*, m.p. 289° (decomp.); *hydrochloride*, m.p. 335° (decomp.),  $[\alpha]_D^{25} + 72.80^\circ$  in H<sub>2</sub>O; *picrate*, m.p. 166°; *platinichloride*, m.p. 290—292° (decomp.)]. (III) with MeI gives an ill-defined *product*, m.p. 280—300°; with CH<sub>2</sub>O-HCO<sub>2</sub>H followed by KI it furnishes the *hydriodide* of (I). (III) in HCl with NaNO<sub>2</sub> forms a *NO*-derivative (*hydrochloride*, m.p. 282—284°). *Conimine* in H<sub>2</sub>SO<sub>4</sub> gives rise to *isoconimine* (IV), C<sub>22</sub>H<sub>36</sub>N<sub>2</sub>,  $[\alpha]_D^{25} + 89^\circ$  in EtOH [*hydriodide*, m.p. 332° (decomp.); *carbonate*; *hydrochloride*, m.p. 335—336° (decomp.); *picrate*, m.p. 135°; *platinichloride*, m.p. 285—288° (decomp.); (*NO*)<sub>2</sub>, m.p. 123—125°, and *Ac*, m.p. 139—140° [*bromination product*, m.p. 185—186° (decomp.)], derivatives. The Me<sub>2</sub> derivative of (I) (CH<sub>2</sub>O-HCO<sub>2</sub>H) is identical with (I). *isoConessine* is about three times as active (respiration of frogs) as conessine.

E. W. W.

**Alkaloids of *Erythrophloeum guineense*.** G. DALMA (Annali Chim. Appl., 1935, 25, 569—571). From the bark of the West African red-water tree were isolated *cassaine*, C<sub>24</sub>H<sub>36</sub>O<sub>4</sub>N, m.p. 141,  $[\alpha]_D^{20} - 103^\circ$  in EtOH, *cassaidine*, C<sub>24</sub>H<sub>43</sub>O<sub>5</sub>N, m.p. 131°, *norcassaidine*, C<sub>23</sub>H<sub>41</sub>O<sub>5</sub>N, m.p. 131°, and *omofteit*, C<sub>56</sub>H<sub>90</sub>O<sub>9</sub>N<sub>2</sub>. Colour reactions are given.

O H

**Reduction in morphine series. VII. *ψ*-Codemone.** R. E. LUTZ and L. SMALL (J. Amer. Chem.

Soc., 1935, 57, 2651—2656).—The alicyclic double linking in  $\psi$ -codeinone (I) [*hydrochloride* (+H<sub>2</sub>O) (II), m.p. 201—203° (decomp.)] is considered to be between C6 and C7 [as suggested by Gulland and Robinson (A., 1926, 83)] since treatment with an excess of semicarbazide gives (as with  $\alpha\beta$ -unsaturated ketones) *semicarbazinodihydro- $\psi$ -codeinonesemicarbazone* (+H<sub>2</sub>O), m.p. 225—227° (uncorr.; decomp.). Condensation of (I), which is prepared by oxidation (method: Knorr and Horlein, A., 1907, i, 547) of  $\psi$ -codeine or *allo- $\psi$ -codeine*, with PhCHO does not indicate the  $\cdot\text{CH}_2\cdot\text{CO}\cdot$  group since codeine undergoes the same reaction. Reduction (H<sub>2</sub>, PtO<sub>2</sub>, AcOH) of (II) affords the non-phenolic *dihydro- $\psi$ -codeinone* (III), m.p. 113°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> +37° in EtOH [*hydrochloride* (+H<sub>2</sub>O), m.p. 172—173°; *hydriodide*, m.p. 250—255° (decomp.); *H tartrate* (?), m.p. 199—200° (uncorr.); *oxime*, m.p. 244—245°], reduced (Na, EtOH) to *dihydro- $\psi$ -codeine-A* (A., 1933, 170) and converted by Ac<sub>2</sub>O-NaOAc into *de-N-acetyldihydro- $\psi$ -codeinone enol acetate*, m.p. 191.5—192°. Reduction (H<sub>2</sub>, PtO<sub>2</sub>, EtOH) of (I) gives the phenolic *tetrahydro- $\psi$ -codeinone* (+0.5H<sub>2</sub>O) (IV), m.p. 137—138.5°, m.p. (anhyd.) 170—171°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> +8° in EtOH [*hydrochloride* (+2H<sub>2</sub>O), m.p. 165—166° (decomp.); *hydriodide* (+H<sub>2</sub>O), m.p. 154—155°; *Ac derivative*; *oxime*, m.p. 218—219° (lit. 137°)], which differs considerably from Hill's description (Diss., Frankfurt, 1925). (IV) does not react with CH<sub>2</sub>N<sub>2</sub>; it is reduced, as is (I), by Na and EtOH in N<sub>2</sub> to *tetrahydro- $\psi$ -codeine*. Demethylation (48% HBr) of (III) gives *dihydroisomorphinone* (V), m.p. 198°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> +46° in EtOH. (I) and MgMeI afford the phenolic *methylidihydro- $\psi$ -codeinone* (VI), m.p. 213.5—214.5°, which could not be reduced (various methods); no oxime or semicarbazone could be prepared. (VI) may be formed by 1:2- or 1:4-addition involving fission of the  $\cdot\text{O}\cdot$  ring. All m.p. are corr. unless stated otherwise. Pharmacological data for (III) and (V) are given. H. B.

**Strychnos alkaloids. LXXXIX. Behaviour of strychninonic acid towards barium peroxide.** H. LEUCHS and W. DIELS (Ber., 1936, 69, [B], 47—48).—Treatment of strychninonic acid with Ba(OH)<sub>2</sub>, H<sub>2</sub>O<sub>2</sub> at 85—90° gives the *NH<sub>2</sub>-acid* (I), C<sub>18</sub>H<sub>18</sub>O<sub>4</sub>N<sub>2</sub>, m.p. 248—255°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> -18.8° in H<sub>2</sub>O [*monoperchlorate*, m.p. 240—243° (decomp.) after softening at 230°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> -17.4° ( $\pm$ 8°); *semiperchlorate* (I) with NaOH-MeOH-MeI gives the *product*, C<sub>19</sub>H<sub>20</sub>O<sub>4</sub>N<sub>2</sub> (*perchlorate*, decomp. 262°), and a mixture of neutral products. H. W.

**Sinomenine. XLIII.** K. GOTO and H. SHISHIDO Bull. Chem. Soc. Japan, 1935, 10, 597—600).—*Bromodemethoxydihydrosinomenine methiodide* (A., 1931, 1171) with hot 2% NaOH affords *1-bromode-N-methyl-demethoxydihydrosinomenine* (A; R' = Br), m.p. 130°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> +7.00° in MeOH (*methiodide*, m.p. 278—279°), which gives a *racemate*, m.p. 148°, with *1-bromode-N-methylidihydro-codeinone*, m.p. 132°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> -8.00° in MeOH. Similarly *de-N-methyl-demethoxydihydrosinomenine* (I) (A; R' = H), m.p. 120°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> +4.00° in MeOH, gives a

*racemate*, m.p. 114—116°, with *de-N-methyldihydro-codeinone* (II), [ $\alpha$ ]<sub>D</sub><sup>20</sup> -4.00° in MeOH (Freund *et al.*, A., 1921, i, 125). Reduction (H<sub>2</sub>-Pd-BaSO<sub>4</sub> in 0.3% HCl) of (I) gives its *H<sub>2</sub>-derivative*, m.p. 93—97°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> +50.00° in EtOH, which gives a *racemate*, m.p. 113—116°, with the *H<sub>2</sub>-derivative*, m.p. 95—98°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> -50.5° in EtOH, of (II). Catalytic reduction of thebaine in < N-HCl affords *dihydrothebaine* (III) and a little *dihydrothebainone* (IV); in 2.5N-HCl (IV), *dihydrocodeinone* (V), and *metathebainone* (VI), are obtained, whereas in 5N-HCl a 75% yield of (VI) is obtained (Cahn, A., 1933, 1061). (III) is hydrolysed by cold 2N-HCl to (V). The mixture (A., 1930, 1600) of *demethoxydihydrosinomenine* [(+)-*dihydrothebainone*] [*hydrobromide*, m.p. 291° (decomp.); *hydrochloride*, m.p. 293° (decomp.)] and *demethoxydihydrosinomeninol* [(+)-*dihydrothebainol*] is separated by dissolution in HBr or HCl, salts of the former crystallising. 1-Bromodemethoxydihydrosinomenine (*oxime*, m.p. 177—178°: the m.p. 263° given in A., 1930, 795, is that of the oxime hydrochloride) has been obtained in a form, m.p. 167°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> +78.67° in CHCl<sub>3</sub>, which gives a *racemate*, m.p. 190—193°, with 1-bromodihydrothebainone. J. W. B.

**New alkaloid of ergot.** S. SMITH and G. M. TIMMIS (Nature, 1936, 137, 111).—Ergot contains an *alkaloid*, probably C<sub>30</sub>H<sub>35</sub>O<sub>5</sub>N<sub>5</sub>, decomp. approx. 228°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> +522° in CHCl<sub>3</sub>. L. S. T.

**Dimorphism of ergometrine.** R. L. GRANT and S. SMITH (Nature, 1936, 137, 154).—A second *modification*, m.p. 212° (decomp.), of ergometrine, m.p. 162—163° (decomp.), has been cryst. in long needles from COMe<sub>2</sub>. The form of low m.p. tends to pass into the less fusible on keeping, and is the more sol. Both forms have [ $\alpha$ ]<sub>D</sub><sup>20</sup> +62.6°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> +42.2° in EtOH. L. S. T.

**Aconitine. I. Oxonitin and the oxidation of aconitine with nitric acid and chromic acid.** A. LAWSON (J.C.S., 1936, 80—83).—Oxonitin is oxidised (HNO<sub>3</sub>) with loss of OMe to an *acidic compound*, C<sub>31</sub>H<sub>35</sub>O<sub>14</sub>N<sub>3</sub>, m.p. 263° (decomp.). Aconitine (I) is oxidised (CrO<sub>3</sub>) to *aconitoline*, C<sub>30</sub>H<sub>37</sub>O<sub>9</sub>N, m.p. 220°, hydrolysed (NaOEt) with loss of BzOH to a base, C<sub>30</sub>H<sub>33</sub>O<sub>8</sub>N [*hydrochloride* (+3H<sub>2</sub>O), m.p. 222°; *Ac derivative*, m.p. 239°]. (I) with HNO<sub>3</sub> gives an *acid*, C<sub>30</sub>H<sub>35</sub>O<sub>13</sub>N<sub>2</sub>, m.p. 268° (decomp.), containing NO, hydrolysed with loss of BzOH and AcOH to a *substance*, C<sub>22</sub>H<sub>29</sub>O<sub>11</sub>N<sub>3</sub>, m.p. 201°, and with HCl converted into an *amino-acid*, C<sub>31</sub>H<sub>36</sub>O<sub>12</sub>N<sub>2</sub>·HCl·2H<sub>2</sub>O, m.p. 218° (decomp.). Aconitoline with HNO<sub>3</sub> yields a *nitroso-acid*, C<sub>29</sub>H<sub>33</sub>O<sub>13</sub>N<sub>3</sub>, m.p. 186° (decomp.), which with HCl forms an *NH<sub>2</sub>-acid*, C<sub>29</sub>H<sub>31</sub>O<sub>12</sub>N<sub>2</sub>, m.p. 250° (decomp.), hydrolysed (NaOEt) to an *acid*, C<sub>22</sub>H<sub>30</sub>O<sub>11</sub>N<sub>2</sub>·HCl·H<sub>2</sub>O, m.p. 218° (decomp.). Oxidation of (I) with HNO<sub>2</sub> gives a *substance*, C<sub>31</sub>H<sub>40</sub>O<sub>12</sub>N<sub>2</sub>, m.p. 276° (decomp.). These results are in agreement with the formula for (I) of Spath and Galinovsky (A., 1931, 1313). F. R. S.

**Arsenical derivatives of thymol.** V. BELLAVITA and M. BATTISTELLI (Annali Chim. Appl., 1935, 25, 631—634).—2-Aminothymol is diazotised and converted by As<sub>2</sub>O<sub>3</sub> in NaOH (Cu) into 2-hydroxy-6-methyl-3-propylphenylarsinic acid (I), m.p. 189—190° (decomp.). (I) is resistant to reduction by H<sub>3</sub>PO<sub>2</sub>; with

(A.)

R =  $\cdot[\text{CH}_2]_2\cdot\text{NH}_2$

R' = H, m.p. 120°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> +4.00° in MeOH, gives a

$\text{Na}_2\text{CO}_3$ -KI- $\text{SO}_2$  it gives after 10 days 2-hydroxy-6-methyl-3-propylphenylarsinoxide, unaltered at  $320^\circ$ . In EtOH with HCl (or HBr) and  $\text{SO}_2$ , (I) yields respectively 2-hydroxy-6-methyl-3-propylphenyldichloro-, m.p.  $60-62^\circ$ , and dibromo-arsine, b.p.  $140^\circ/12$  mm. With Br in AcOH, (I) forms 5-bromo-2-hydroxy-6-methyl-3-propylphenylarsinic acid, m.p.  $204-205^\circ$ ; the corresponding 5-I-compound, m.p.  $195^\circ$ , is obtained in alkaline solution using 0.1N-I. (I) gives no colour with  $\text{FeCl}_3$ . E. W. W.

**Polymethylbenzenes. XIII. Mercuration.** L. I. SMITH and F. L. TAYLOR (J. Amer. Chem. Soc., 1935, 57, 2370-2372).—The hydrocarbons are heated with  $\text{Hg}(\text{OAc})_2$  in MeOH-AcOH; the resulting  $\text{OAc}\cdot\text{Hg}\cdot$  derivatives (in  $\text{CHCl}_3$ , EtOH, or EtOH- $\text{CHCl}_3$ ) with aq. EtOH-HCl, -NaBr, and -NaI (<1 equiv.) give the  $\text{HalHg}$ -compounds. The following are described: pentamethylbenzene ( $\text{OAc}\cdot\text{Hg}\cdot$ , m.p.  $180^\circ$ ,  $\text{ClHg}\cdot$ , m.p.  $205^\circ$ , and  $\text{BrHg}\cdot$ , m.p.  $195-196^\circ$ , derivatives); durenene ( $\text{OAc}\cdot\text{Hg}\cdot$ , m.p.  $158-159^\circ$ ,  $\text{ClHg}\cdot$ , m.p.  $188-189^\circ$ ,  $\text{BrHg}\cdot$ , m.p.  $174^\circ$ , and  $\text{IHg}\cdot$ , m.p.  $161-162^\circ$ , derivatives); isodurenene ( $\text{OAc}\cdot\text{Hg}\cdot$ , m.p.  $108^\circ$ ,  $\text{ClHg}\cdot$ , m.p.  $174^\circ$ ,  $\text{BrHg}\cdot$ , m.p.  $160^\circ$ , and  $\text{IHg}\cdot$ , m.p.  $163-164^\circ$ , derivatives); prehnitene ( $\text{OAc}\cdot\text{Hg}\cdot$ , m.p.  $147^\circ$ ,  $\text{ClHg}\cdot$ , m.p.  $216-217^\circ$ ,  $\text{BrHg}\cdot$ , m.p.  $213-214^\circ$ , and  $\text{IHg}\cdot$ , m.p.  $200^\circ$ , derivatives); mesitylene ( $\text{OAc}\cdot\text{Hg}\cdot$  derivative, m.p.  $102-103^\circ$ );  $\psi$ -cumene (5- $\text{OAc}\cdot\text{Hg}\cdot$  derivative, m.p.  $145-147^\circ$ );  $\text{Hg}(\text{C}_6\text{Me}_5)_2$ , m.p.  $278^\circ$  (lit.  $266^\circ$ ), and  $\text{Hg}$  diduryl, m.p.  $242-243^\circ$ , diisoduryl, m.p.  $217-218^\circ$ , and diprehnityl, m.p.  $200^\circ$ , are prepared from the appropriate  $\text{IHg}\cdot$  derivative and NaI (4 mols.) in EtOH.

H. B.

**Antiseptics. Mercury salts of alkylfluoresceins.** A. NOVELLI (An. Farm. Biochim., 1933, 4, 29-35; Chem. Zentr., 1935, i, 3691).—Mercuration of diacetyl-, dipropionyl-, diethyl-, dipropyl-, dibutyl-, and dihexyl-fluoresceins leads to  $\text{Hg}$  compounds

(I). The antiseptic activity increases with increasing length of the side-chain, R.

Presence of  $\text{CO}$  in R diminishes antiseptic power.

**Action of radioactive substances on proteins.**—See this vol., 301.

**Multivalent amino-acids and peptides. VI.**—See this vol., 379.

**Influence of neutral salts on the optical rotation of gelatin. III, IV.**—See this vol., 288.

**Colloid chemistry of edestin. III.**—See this vol., 288.

**Salting-out and peptisation of edestin by mixtures of two salt solutions.**—See this vol., 288.

**Reducing groups of proteins.** A. E. MIRSKY and M. L. ANSON (J. Gen. Physiol., 1936, 19, 451-459).—Proteins contain, besides SH groups, others which will react with  $\text{K}_3\text{Fe}(\text{CN})_6$ , and are probably in the tyrosine and tryptophan units. Their activity is enhanced by denaturation and by increase of  $p_{\text{H}}$  and

temp., but they differ from SH groups in that their activity depends on the concn. and time of exposure to  $\text{K}_3\text{Fe}(\text{CN})_6$ . F. A. A.

**Thiol and disulphide groups of proteins. II. Relation between number of SH and S-S groups and quantity of insoluble protein in denaturation and in reversal of denaturation. III. Thiol groups of native proteins: haemoglobin and the proteins of the crystalline lens.** A. E. MIRSKY and M. L. ANSON (J. Gen. Physiol., 1936, 19, 427-438, 439-450).—II. No SH groups are detectable (see A., 1935, 506) in native ovalbumin, but on heat-coagulation as many are found as in the fully hydrolysed protein. The same no. of them appears when ovalbumin is denatured by ultra-violet radiation, or at surfaces. The sol. fraction of partly heat-coagulated ovalbumin shows no SH. When serum-albumin is denatured, S-S groups appear, but disappear when denaturation is reversed.

III. Native haemoglobin and the proteins of the cryst. lens contain SH groups, the no. increasing with rise of  $p_{\text{H}}$  from 6.8 to 9.5. On denaturation, more SH groups appear; these latter are active at  $p_{\text{H}}$  vals. so low that those in the native proteins are barely detectable, and thus may be differentiated from them. At  $p_{\text{H}}$  6.8,  $\text{K}_3\text{Fe}(\text{CN})_6$  oxidises the Fe-porphyrin of haemoglobin without affecting the SH groups; at 9.6, the SH groups may be oxidised, by cystine, without affecting the Fe-porphyrin. F. A. A.

**Characterisation and determination of the hydrolysis products of elastin. Isolation of the monoamino-acids by a new technique.** R. ENGELAND (Bull. Soc. Chim. biol., 1935, 17, 1790-1804).— $\text{NH}_2$ -acids are separated by fractional pptn. of the hydrochlorides from MeOH solution. From elastin two  $\text{NH}_2$ -acids,  $\text{C}_{11}\text{H}_{22}\text{O}_4\text{N}_2$  and  $\text{C}_{17}\text{H}_{38}\text{O}_4\text{N}_2$ , are isolated as the Cu salt,  $\text{C}_{11}\text{H}_{20}\text{O}_4\text{N}_2\text{Cu}$ , and the aurichloride,  $\text{C}_{17}\text{H}_{36}\text{O}_4\text{N}_2\cdot 2\text{AuCl}_4$ , respectively. A. L.

**Determination of the m.p. of organic substances.** F. FRANCIS and F. J. E. COLLINS (J.C.S., 1936, 137-142).—A description of apparatus for setting point and m.p. determination. Setting point gives more accurate experimental vals. for transition temp. from solid to liquid. With the apparatus described, existence of metastable forms fusing within  $1^\circ$  of each other can be detected, transition temp. recorded, and a judgment reached on the purity of the specimen. F. R. S.

**Organic micro-analytical practice.** C. WEYGAND and H. HENNIG (Chem. Fabr., 1936, 9, 8-10).—The technique of methods of C, H, N, halogen, S, and OMe-determination, as applied to samples of 0.001-0.01 g., is detailed. J. W. S.

**Determination of carbon and nitrogen by the action of chromic acid under reduced pressure.** C. N. ACHARYA (Biochem. J., 1936, 30, 241-247).—C and N are determined in org. material by oxidation with  $\text{CrO}_3$  and  $\text{H}_2\text{SO}_4$  and the  $\text{CO}_2$  evolved is absorbed and weighed. Subsequent direct distillation of the digest with alkali gives low vals. for N owing to the formation of  $\text{NO}_3^-$  so that a preliminary reduction is necessary. The disturbing influence of Cl is avoided by addition of  $\text{HgO}$ . H. D.

**Analysis of organic compounds containing H and D.** H. ERLÉNMEYER and H. GARTNER (Helv. Chim. Acta, 1936, 19, 129—144).—The customary determination of H in org. compounds which contain H and D gives accurate results only when the content of H is very high. In the general case a differentiation between a H- and D-compound cannot thus be effected or only very inexactly. Generally, the differences in the % of C allow an approx. differentiation between H- and D-compounds but for accurate results a high % of C and H is necessary. Suitable relationships exist in hydrocarbons particularly in those of the paraffin series. A method is described in which the substance (0.05 to 0.15 g.) is burnt with CuO and the water is collected in a tube cooled in solid  $\text{CO}_2\text{-CCl}_4\text{-CHCl}_3$ . It is mixed with 10 c.c. of standard  $\text{H}_2\text{O}$ ; the mixture is distilled and its  $d$  is determined. The sensitiveness is such that in a mixture of isotopic benzenes, approx. PhD, it is just possible to discriminate between  $\text{C}_6\text{H}_{4.995}\text{D}_{1.005}$  and  $\text{C}_6\text{H}_{5.005}\text{D}_{0.995}$ . H. W.

**Determination of organic sulphur by the liquid ammonia-sodium method.** F. J. SOWA, V. G. ARCADE, and J. A. NIEUWLAND (Ind. Eng. Chem. [Anal.], 1936, 8, 49—50).—0.1 g. of substance is dissolved in 175 c.c. of liquid  $\text{NH}_3$  with the help if necessary of an inert solvent and Na is added until the blue colour is permanent. The solution is evaporated (20 c.c.), 3—5 g. of  $\text{NH}_4\text{Cl}$  are added, and the mixture is evaporated to dryness. The residue is taken up in  $\text{H}_2\text{O}$ , oxidised with 2 g. of  $\text{Na}_2\text{O}_2$ , and the S pptd. as  $\text{BaSO}_4$ . The method is accurate and of general applicability. S. C.

***p*-Bromobenzhydrazide as a reagent for the identification of aldehydes and ketones.** S. M. WANG, CHENG-HENG KAO, CHUNG-HSI KAO, and P. P. T. SAH (Sci. Rep. Nat. Tsing Hua Univ., 1935, A, 3, 279—284).—*p*-Bromobenzhydrazide, m.p.  $164^\circ$  (prep. from *p*- $\text{C}_6\text{H}_4\text{Me}\cdot\text{NH}_2$  described), condenses with aldehydes and ketones in boiling 95% EtOH containing a few drops of glacial AcOH yielding *p*-bromobenzoylhydrazones of the following substances: MeCHO, m.p.  $192\text{--}193^\circ$ ; EtCHO, m.p.  $172\text{--}173^\circ$ ;  $\text{Pr}^\text{t}$ CHO, m.p.  $157\text{--}158^\circ$ , Bu $^\text{t}$ CHO, m.p.  $153\text{--}154^\circ$ ; hexaldehyde, m.p.  $144\text{--}145^\circ$ ; *n*-heptaldehyde, m.p.  $124\text{--}125^\circ$ ; PhCHO, m.p.  $242\text{--}243^\circ$ ; *p*-, m.p.  $250\text{--}251^\circ$ , and *m*-, m.p.  $217\text{--}218^\circ$ ;  $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CHO}$ ; furfuraldehyde, m.p.  $218\text{--}219^\circ$ ;  $\text{CHPh}\cdot\text{CH}\cdot\text{CHO}$ , m.p.  $235\text{--}236^\circ$ ; COMe., m.p.  $198\text{--}199^\circ$ ; Me hexyl ketone, m.p.  $131\text{--}132^\circ$ ; CPhMe, m.p.  $192\text{--}193^\circ$ ; *p*- $\text{C}_6\text{H}_4\text{Me}\cdot\text{COMe}$ , m.p.  $212\text{--}213^\circ$ ; benzylideneacetophenone, m.p.  $219\text{--}220^\circ$ ; *m*- $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{COMe}$ , m.p.  $219\text{--}220^\circ$ ; CPh., m.p.  $160\text{--}161^\circ$ ; lævulic acid, m.p.  $158\text{--}159^\circ$ ; Et, m.p.  $128\text{--}129^\circ$ , and  $\text{C}_6\text{H}_5\text{Ph}$ , m.p.  $123\text{--}124^\circ$ , lævulate;  $\text{CH}_2\text{Ac}\cdot\text{CO}_2\text{Et}$ , m.p.  $74\text{--}75^\circ$ . Primary and sec. alcohols are oxidised and then identified by this method. H. W.

**Determination of thiol and disulphide compounds, with special reference to cysteine and cystine.** IV. Accurate determination of thiol compounds. Standardisation of cysteine hydrochloride. V. Cystine determination by sulphite and phospho-18-tungstic acid reagent. K. SHINO-

HARA. VI. Reaction of ascorbic acid and glutathione with phospho-18-tungstic acid reagent. VII. Modified phospho-18-tungstic acid method of determining cysteine, cystine, and ascorbic acid in urine. K. SHINOHARA and K. E. PADIS (J. Biol. Chem., 1936, 112, 671—682, 683—696, 697—708, 709—721; cf. this vol., 60).—IV. Cysteine (I) and  $\text{SH}\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$  are allowed to react with a deficiency of  $\text{HgCl}_2$  and the excess is determined colorimetrically by phospho-18-tungstic acid (II).  $\text{H}_2\text{O}$  and a little cystine (III) are the chief impurities in commercial (I). (III) does not interfere with the determination of (I) by this method.

V. (III) is reduced by  $\text{NaHSO}_3$  and then determined colorimetrically by (II).  $\text{NaHSO}_3$  alone develops little colour;  $\text{HgCl}_2$  inhibits formation of colour by (III). Various reducing agents, but not (I), interfere.

VI. Ascorbic acid (IV) is determined colorimetrically by (II), the colour being twice as intense as that due to equimolar amounts of (I). The colour is not affected under specified conditions by  $\text{HgCl}_2$ , or small amounts of  $\text{CH}_2\text{O}$ . (I), (III), and (IV) are thus determined in the same solution by use of  $\text{CH}_2\text{O}$ ,  $\text{HgCl}_2$ , and (II). Oxidised (IV) gives no colour. Glutathione gives irregular results, probably due to hydrolysis, and interferes with the methods.

VII. Modifications are necessary for determinations in urine. Fresh normal urine contains 0—0.9 mg. of (I), 1.1—4.8 mg. of (III), and 3.2—26.8 mg. of (IV) per 100 c.c. R. S. C.

**Determination of cystine by Sullivan's method:** supposed cleavage of cystine from casein by dilute alkali. H. J. LEE (Austral. J. Exp. Biol., 1936, 13, 229—237).—Various factors may interfere with the determination of cystine (I) by Sullivan's method. The conclusion of Jones and Gersdorff (A., 1934, 313) that treatment of casein by dil. alkali destroys some of the (I) is vitiated by their failure to make allowance for the interfering effect of the casein hydrolysate on the determination of (I).

W. O. K.

**Titration of amino-acids in glacial acetic acid solution.** G. F. NADEAU and L. E. BRANCHEN (J. Amer. Chem. Soc., 1935, 57, 1363—1365).— $\text{NH}_2$ -acids (I) (in glacial AcOH) are determined by titration with 0.1*N*- $\text{HClO}_4$  using crystal-violet,  $\alpha$ -naphtholbenzein, or benzoylauramine as indicator; picric acid does not interfere. (I) insol. in AcOH are determined by dissolution in an excess of 0.1*N*- $\text{HClO}_4$  and back-titration with guanidine acetate. The results agree with potentiometric titration (in AcOH using chloranil electrode). H. B.

**Colorimetric determination of allantoin.** G. MOURROT (Bull. Soc. Chim. biol., 1935, 17, 1845—1850).—The method is a modification of that of Fosse (A., 1931, 976). The allantoinic acid is hydrolysed to glyoxylic acid, which is determined colorimetrically using  $\text{NHPh}\cdot\text{NH}_2$ . A. L.

**Weydel reaction for xanthines.** G. DENIGÈS (Bull. Trav. Soc. Pharm. Bordeaux, 1934, 72, 345—355; Chem. Zentr., 1935, i, 3162).—Colour reactions for caffeine, theobromine, theophylline, xanthine, and

guanine are described; the underlying mechanism and the influence of constitution are discussed.

H. N. R.

**Spectrophotometric determination of chlorophyll *a* and *b*, carotene, and xanthophyll.**—See this vol., 396.

## Biochemistry.

**Effect of respiration of pure oxygen on metabolism.** P. BIELCHOWSKY and S. THADDEA (Z. klin. Med., 120, 330—340; Chem. Zentr., 1934, ii, 3399).—Blood-ketones in man, if high, are diminished, and  $p_H$  is shifted towards the alkaline side as the result of decreased alveolar  $CO_2$  tension. The lactic acid curves obtained by injections of Na lactate and adrenaline in man or the dog lie considerably lower in  $O_2$  respiration.

R. N. C.

**Respiration of carbon dioxide in narcosis and in paralysis of the respiratory centre.** H. FRANKEN (Schmerz, Narkose, Anästhesie, 1934, 7, 26—36; Chem. Zentr., 1934, ii, 3646).

R. N. C.

**Simple valveless apparatus for determination of gaseous metabolism in man.** F. FOLDES (Biochem. Z., 1935, 282, 303—307).—The apparatus (cf. the similar apparatus for dogs, A., 1935, 238) is described. The error of duplicate experiments is  $\pm 3\%$ .

P. W. C.

**Respiratory characteristics of the blood of the seal.** L. IRVING, O. M. SOLANDT, D. Y. SOLANDT, and K. C. FISHER (J. Cell. Comp. Physiol., 1935, 6, 393—403).—The capacity of the blood for  $CO_2$  and its buffering power are  $<$  those of human blood.  $O_2$  capacity vals. and dissociation curves are given.

R. N. C.

**Vapour pressure of the blood of arthropods from swift and still waters.** H. M. FOX and E. J. BALDES (J. Exp. Biol., 1935, 12, 174—178).—No correlation was apparent between the v.p. of blood and the  $O_2$  consumption.

CH. ABS. (p)

**Effect of oxygenation of the external medium on the composition of blood in *Scyllium canicula*.** E. A. PORA (Compt. rend. Soc. Biol., 1936, 121, 194—196).—Total osmotic pressure, Na, Ca, proteins, org. substances, and the alkaline reserve are increased, whilst plasma-Cl falls; corpuscular Cl is unaffected. Mineral salts in serum and muscle increase simultaneously, and  $H_2O$  passes from the blood to the muscles.

R. N. C.

**Variation of blood- $p_H$  and blood-gas after injection of sodium silicate.** K. DAIKOKU (Trans. Soc. Path. Japon., 1934, 24, 72—76).—Continuous injection caused a decrease in blood- $p_H$  and -gas.

CH. ABS. (p)

**Regeneration of blood in fish following bleeding.** L. BAUDIN (Compt. rend. Soc. Biol., 1936, 121, 330—332).

R. N. C.

**Effects of extracts of pituitary gland on sedimentation of red blood corpuscles of normal and hypophysectomised dogs.** T. ICHIJO (Sei-i Kwai Med. J., 1934, 53, No. 6, 123—132).—Data obtained by Kowarski's apparatus are given.

CH. ABS. (p)

**Determination of rate of sedimentation of blood corpuscles. Effect of globulin solutions**

**on the rate *in vitro*.** I. BINET and I. KRASZNAI (Biochem. Z., 1936, 283, 190—198).—Westergreen's method gives trustworthy results only if const. temp. and  $p_H$  are maintained in the tubes. *In vitro* the rate of sedimentation of washed red blood corpuscles and to a smaller extent that of blood is diminished by addition of globulin.

W. McC.

**"Urea surcharge" (Delaunay) of the erythrocytes of *Sipunculus*: distribution of urea between erythrocytes and plasma in the coelomic liquids charged with erythrocytes.** M. FLORKIN (Compt. rend. Soc. Biol., 1936, 121, 158—160).—The erythrocytes of the coelomic liquid of *Sipunculus* are surcharged with urea, but not those of *Echiurus*, *Glycera*, or *Capitella*.

R. N. C.

**Effect of heparin on the permeability of the erythrocytes to adrenaline.** M. KUCZAROW (Klin. Woch., 1934, 13, 734—735; Chem. Zentr., 1934, ii, 3780—3781).

R. N. C.

**Characteristics of the stability of corpuscular glucose subjected to washing with physiological solution.** G. PATRASSI and U. TEODORI (Boll. Soc. ital. Biol. sperim., 1935, 10, 525—526).—Repeated washing of erythrocytes with 0.9% NaCl reduces their glucose to a steady min., which in erythrocytes from diabetics is slightly  $>$  from normal subjects.

R. N. C.

**Corpuscle resistance and bilirubinæmia in young mammals with trychophytia after slow dosage with thallium acetate.** I. GATTO and G. MELODIA (Pediatria, 40, 230—235; Chem. Zentr., 1934, ii, 3397).—Corpuscle resistance is increased and bilirubinæmia diminished or abolished.

R. N. C.

**Diurnal variations in concentration of red blood cells and hæmoglobin.** J. J. SHORT (J. Lab. Clin. Med., 1935, 20, 708—713).

CH. ABS. (p)

**Percentage of hæmoglobin compared with the volume of erythrocytes. Importance of this relation in correcting the Van Allen determination of the volume of platelets.** K. K. NYGAARD and D. L. DUXBURY (J. Lab. Clin. Med., 1935, 20, 767—772).—The hæmoglobin content expressed as g. per 100 c.c. is closely related to the vol. of erythrocytes expressed as vol.-% of the sample. Tables for intercalculation are given.

CH. ABS. (p)

**0.1N-Hydrochloric acid as diluent for combined leucocyte and hæmoglobin determinations.** C. A. PONS and W. P. BELK (J. Lab. Clin. Med., 1935, 20, 766—767).—Blood diluted with 0.1N-HCl is suitable for white cell counts and for examination in the Huden-Hausser hæmoglobinometer.

CH. ABS. (p)

**Birth pains and the blood of the new-born.** Z. HORVATH and C. HOLLÓSI (Amer. J. Dis. Children, 1935, 49, 689—694).

CH. ABS. (p)

**Determination of hæmoglobin in experimental anæmia in rabbits.** R. DAMADE, L. SERVANTIE, and J. FERVILLE (Compt. rend. Soc. Biol., 1936, 121, 229—232).—The methods of Sahli and Autenrieth and of Wong are recommended. R. N. C.

**Solutions of hæmoglobin stabilised with time.** I, II. W. DUCE (Boll. Soc. ital. Biol. sperim., 1935, 10, 376—379, 379—382).—I. Solutions of hæmoglobin (I) after prolonged dialysis are coagulated by boiling, and by 2*N*-NaCl, or EtOH, are coloured red by slight acidification or alkalis, and pptd. by HNO<sub>3</sub>, AcOH, Hg(NO<sub>3</sub>)<sub>2</sub>-HNO<sub>3</sub>, and K<sub>4</sub>Fe(CN)<sub>6</sub> (II), but not by CuSO<sub>4</sub>, NiSO<sub>4</sub>, AgNO<sub>3</sub>, basic Pb acetate, or HgCl<sub>2</sub>. After prolonged storage at room temp. dialysed (I) is coagulated only by 2*N*-NaCl, is coloured brown by acids and alkalis, and pptd. by all the above reagents except (II).

II. The absorption bands of (I) in the red are displaced towards the red end by prolonged dialysis and storage. The absorption quotient falls.

R. N. C.

**Sulphur content of hæmoglobin with special reference to blood-groups.** G. BALASSA (Biochem. Z., 1936, 283, 222—228).—In man the hæmoglobin (I) of the blood of some individuals contains 0.611% of S whilst that of others contains 0.662%, the corresponding Fe:S ratios and min. mol. wts. being, respectively, 4:13, 4:14, and 68,000, 34,000. The blood of individuals belonging to blood-groups A and B contains the second, that of the blood of individuals belonging to blood-group O the first, kind of (I).

W. McC.

**Optical properties of acidified solutions of -<sub>2</sub> and CO-hæmoglobin in blood.** G. BARKAN (Z., 1936, 283, 241—252; cf. A., 1930, 107).—Spectrophotometric examination indicates that the darker colour of the solutions containing CO is due to a difference in the degree of dispersion.

W. McC.

**Analysis of the spectra of hæmoglobin derivatives.** D. L. DRABKIN (Amer. J. Med. Sci., 1935, 189, 154).—Absorption curves are represented as ions a no. individual bands. Oxy- (I), ca h (II), cyano-, and two forms of met-hæmo- n e certain bands in common. Their position is discussed. The α-bands of (I) and (II) do not belong to this series and probably represent the union of hæmoglobin with a gas.

CH. ABS. (p)

**Aliphatic amino-content of the oxyhæmoglobins of animals.** K. GERGELY (Biochem. Z., 1936, 283, 263—272; cf. A., 1933, 107).—The average NH<sub>2</sub>-N contents of h dog-, and ox-oxyhæmoglobin are, respectively, 1.96—12.48, 13.14, and 13.28%. The vals. are not altered by repeated recrystallisation.

W. McC.

**Differentiation of the pigments of human serum.** R. SULLMANN, E. SZECSENYI-NAGY, and F. VARRÓ (Biochem. Z., 1936, 283, 263—272; cf. A., 1933, 107).—The pigments may be determined by advantage of their differing solubilities in ac. F<sub>3</sub> and light petroleum and may be separated by autographic adsorption on Al<sub>2</sub>O<sub>3</sub>. With the exception of very small amounts of non-diazotisable bilirubin-like pigments the only pigments in normal

human serum are bilirubin (I), carotene, and xanthophyll. (I) in aq. EtOH is determined after treatment with SO<sub>3</sub>H·C<sub>6</sub>H<sub>4</sub>·N<sub>2</sub>Cl. The pigments produced by ultra-violet irradiation of (I) are insol. in light petroleum and cannot be diazotised. W. McC.

**New crystalline derivative of blood-pigments.** M. WAGENAAR (Z. anal. Chem., 1935, 103, 417—418).—The object to be tested for blood is moistened on a microscope slide with COMe<sub>2</sub>, and a drop of dil. mineral acid is added. Characteristic crystals of acetone-hæmin are produced with the dried residue from 0.05 mg. of blood.

J. S. A.

**Spectrophotometric investigation of cyano-compounds of blood-pigments.** S. SCHONBERGER and P. BALINT (Biochem. Z., 1936, 283, 210—221; cf. A., 1935, 999).—In the visible part of the spectrum the absorption curves of cyanomethæmoglobin (I), cyano-NH<sub>2</sub>-parahæmatin, cyano-C<sub>5</sub>H<sub>5</sub>N-parahæmatin, and cyanohæmatin are identical and exhibit a max. at 541 mμ. In the ultra-violet (I) and cyanoparahæmatin (but not cyanohæmatin) exhibit an intense well-defined band at 424 mμ. The sp. extinctions in the visible are decreased 15% by increasing the alkalinity. The results throw light on the constitution of blood-pigments.

W. McC.

**Variations of osmotic pressure and of the size of hæmocyanin molecules during a long fast (in summer or hibernating) of varieties of *Helix*.** A. ROCHE and J. ROCHE (Compt. rend., 1935, 201, 1522—1524; cf. A., 1934, 673).—The mol. size of hæmocyanin in *H. pisana* and *H. pomatia* is about halved by fasting. This may be the mechanism for H<sub>2</sub>O retention within the animal.

J. L. D.

**Reticulo-endothelial origin of fibrinogen: comparative study of the fibrinogenetic action of some carioclasts.** P. CAMPELLONE (Boll. Soc. ital. Biol. sperim., 1935, 10, 497—499).

R. N. C.

**Micro-Kjeldahl technique for determining fibrinogen.** H. R. GARBUTT and R. S. HUBBARD (J. Lab. Clin. Med., 1935, 20, 758—761).—Plasma (0.5 c.c.) is mixed with 24 c.c. of 0.85% NaCl and 0.5 c.c. of 2.5% CaCl<sub>2</sub> solution. The clot is removed centrifugally, washed with 0.05% CaCl<sub>2</sub> solution, digested with the Folin-Wu mixture, and diluted to 10 c.c. N is determined by nesslerisation.

CH. ABS. (p)

**Protein and electrolyte contents of the plasma and transudates (serous effusions and subcutaneous fluid).** L. ANTOGNETTI (Pathologica, 1935, 27, 182—189).—A progressive and parallel decrease occurs in the [H<sup>+</sup>] and protein concn. in the order erythrocytes, plasma, serous effusions, subcutaneous transudates. Variations in [HCO<sub>3</sub><sup>-</sup>] are in the reverse order. The Donnan membrane equilibrium explains the facts.

CH. ABS. (p)

**Protein equilibrium of blood-serum in anaphylactic states.** AUBRY, THIODET, and RIBERE (Compt. rend. Soc. Biol., 1935, 120, 1257—1259).—Protein equilibrium is disturbed in anaphylactic states, particularly urticaria, albumins remaining steady whilst globulins fall considerably.

R. N. C.

**Protein, lipin, and total cholesterol content of the serum of the normal cat.** L. BLANCHARD (Bull. Soc. Chim. biol., 1935, 17, 1677—1692).—The vals. for the serum-protein, -serine, -globulin, total serum-lipins, and cholesterol of the normal cat are  $73.44 \pm 8.64$ ,  $38.35 \pm 6.97$ ,  $34.78 \pm 8.72$ ,  $8.63 \pm 1.92$ , and  $1.03 \pm 0.20$  g. per 1000 g., respectively. These vals. are of the same order as those for the dog and for man. A. L.

**Influence of ingestion of colostrum on proteins of the blood sera.** I. P. EARLE (J. Agric. Res., 1935, 51, 479—490).—Sera of new-born foals, kids, pigs, and lambs are deficient in euglobulin (I) and low in pseudoglobulin I (II). On ingestion of colostrum (I) and (II) increase rapidly. With foals the amounts of (I) and (II) absorbed are related to the quantity of colostrum ingested. E. P.

**Determination of the tyrosine index of serum polypeptides.** R. LEFAUX (Bull. Soc. Chim. biol., 1935, 17, 1822—1827).—The difference in colour intensity between the  $\text{CCl}_3\text{-CO}_2\text{H}$  and phosphotungstic acid filtrates of the material after treatment with conc.  $\text{HNO}_3$  and aq.  $\text{NaOH}$  is measured. A. L.

**Polypeptidaemia in anaphylactic shock.** M. POLONOVSKI, C. GERNEZ, and J. DRIESSENS (Compt. rend. Soc. Biol., 1936, 121, 37—38).—Blood-polypeptides show no significant modification either in anaphylactic shock or during sensitisation. R. N. C.

**Polypeptidaemia during anaphylactic shock.** F. MAIGNON (Compt. rend. Soc. Biol., 1936, 121, 225—226).—A reply to Polonovski, Gernez, and Driessens (see above). R. N. C.

**Hyperazotæmia of neuro-central origin.** P. JEDŁOWSKI (Boll. Soc. Ital. Biol. sperim., 1935, 10, 615—618). R. N. C.

**Variation of residual nitrogen in blood after injection of sodium silicate solution.** H. AKABANE (Trans. Soc. Path. Japon., 1934, 24, 76—81).—Residual N increased after injection. CH. ABS. (p)

**Influence of protein feeding on the nitrogenous blood constituents in the dog.** L. SAS (Biochem. Z., 1935, 282, 308—316).—The blood-residual-N is greatly increased by protein feeding, due in the initial stages to increase in blood-urea. The polypeptide-N shows no characteristic changes. In animals receiving a N-free diet, blood-urea decreases, but residual N remains unchanged. P. W. C.

**Blood- and urinary nitrogen of a lamelli-branch mollusc (*Anodonta cygnea*).** M. FLORKIN and G. BOSSON (Compt. rend. Soc. Biol., 1935, 120, 1368—1369).—Total, protein-, and non-protein-N vals. for blood and urine at different seasons are given. R. N. C.

**Non-protein-nitrogen content of blood of healthy Korean adults.** H. S. LEE (J. Chosen Med. Assoc., 1934, 24, 1541—1548).—In most cases, vals. varied from 29 to 43 mg. per 100 c.c. of blood (mean for 79 cases  $36.11 \pm 0.83$ ). CH. ABS. (p)

**Adenine nucleotide content of human blood.** II. Correlation with hæmoglobin. M. V. BUELL (J. Biol. Chem., 1936, 112, 523—530; cf. A., 1935,

373).—There is a statistically significant correlation between the adenine nucleotide and hæmoglobin contents of the erythrocytes. J. N. A.

**Oxidised/reduced glutathione ratio in acute oxidosis.** W. LIBBRECHT and A. MASSART (Compt. rend. Soc. Biol., 1935, 120, 1330).—The oxidised/reduced glutathione (I) ratio of rabbits' blood is increased by prolonged exposure to air or  $\text{O}_2$  *in vitro*, but is reduced by exposure to pure  $\text{O}_2$  at high pressures *in vivo*; the state of (I) depends therefore on oxidation in the tissues. R. N. C.

**Liver and glutathione.** L. BINET and G. WELLER (Compt. rend., 1935, 201, 992—993).—In fasting dogs, total glutathione (I) (oxidised+reduced) in the blood from the portal vein is 9%, and in the suprahepatic vein 44%, > in blood from the femoral artery. During digestion, the figures are 51% and 27%, respectively, indicating that during fasting the blood absorbs (I) from the liver, and deposits (I) during digestion. F. A. A.

**Determination of glyoxalines in serum.** A. SCHWARTZ and A. RIEGERT (Compt. rend. Soc. Biol., 1935, 120, 1309—1312).—The method of Loeper *et al.* is unsatisfactory. R. N. C.

**Does the blood contain acetylcholine?** R. AMMON (Klin. Woch., 1935, 14, 453—456).—Acetylcholine cannot be detected chemically or biologically in the blood. R. N. C.

**Arginine as the cause of the non-specificity of analytical methods for blood-guanidine.** M. ZAPPACOSTA (Diagnostica tec. lab. [Napoli], 1934, 5, 919—927).—Reagents for colorimetric tests give the same colour intensity with guanidine (I) as with equimol. quantities of arginine (II). (II), like (I), is adsorbed by C and 70% of it may be eluted with 0.02N-HCl in EtOH. CH. ABS. (p)

**Indole. II. Effect of indole on blood-sugar, urea-nitrogen, and blood-amino-acids.** III. Indolæmia provoked by ligaturing the hepatic peduncle: indican-indole index. E. MACCHIA (Boll. Soc. Ital. Biol. sperim., 1934, 9, 1314—1315, 1935, 10, 528—530).—II. Indole (I) temporarily increases blood-sugar in dogs, but scarcely affects non-protein-N and  $\text{NH}_2$ -acids.

III. Ligature of the hepatic peduncle in the dog after injection of (I) increases blood-(I) and reduces blood-indican. The liver is hence concerned in (4) metabolism. The indican-(I) index is defined. R. N. C.

**Blood-lipins, -calcium, and -potassium during experimental excitation of the hypothalamus, in dogs.** A. VAN BOGAERT and L. VAN MEEL (Compt. rend. Soc. Biol., 1936, 121, 199—201).—Blood-lipins are temporarily depressed, the fall being almost exclusively due to decrease of fatty acids. Cholesterol and unsaponifiable material are scarcely affected.  $\text{Ca}$  sometimes shows a slight temporary rise, and  $\text{K}$  slight fall. R. N.

**Serum-lipins by a micro-gravimetric technique.** W. R. WILSON and A. E. HANSEN (J. Biol. Chem., 1936, 112, 457—468).—The inorg. P and the wt., total acidity, and I val. of the fatty acids or saponifiable fraction and the I val. of the unsaponi-

able fraction of the serum-lipins were determined in 2.5–5 c.c. of serum. The mean total, unsaponifiable, and saponifiable lipins were 0.657, 0.260, and 0.362%, respectively. 81% of the lipin-P is found in the saponifiable fraction. H. D.

**Carotenæmia.** E. BOUNIN and M. LÉVINSON (Z. Vitaminforsch., 1935, 5, 12–21).—Carotenæmia is associated with tuberculosis, diabetes, typhus, malaria, metabolic disturbances, spleen and liver diseases, and in normal persons with a carotene-rich diet. The subnormal oxidation of carotenoids is related to the concomitant hypocholesterolaemia. F. O. H.

**Blood-cholesterol in the carotid artery, venæ cavæ, and portal vein.** F. H. SHILLITO, E. H. BIDWELL, and K. B. TURNER (J. Biol. Chem., 1936, 112, 551–556).—The level of the blood-cholesterol (I) in these vessels was the same for a given animal, whether the whole blood or serum was used, and whether or not cholesterol was administered previously. Passage through the lungs had no effect on (I). Large doses of KI given for 2–14 days produced no variation in the distribution of (I).

J. N. A.  
**Variations in blood-cholesterol in man and in animals.** L. I. PUTSCHINSKI and T. T. GLUHENKI (Bull. Soc. Chim. biol., 1935, 17, 1836–1844).—The cholesterol (I) content of (fasting) human blood over a 24-hr. period varies between 50 and 130 mg. per 100 g. (I) of rabbit and dog blood varies likewise. A. L.

**Influence of a hyperthermal sulphuretted radioactive environment on some constituents of the blood.** A. KRIJANOVSKY (Compt. rend. Soc. Biol. 1935, 120, 1236–1238).—Blood-sugar, -N, -cholesterol, and plasma-Cl are depressed, whilst corpuscular Cl rises, in man in the Luchon radio-vaporarium. R. N. C.

**Blood-sugar of *Cancer pagurus*: nature of reducing substances and factors of variation of blood-sugar.** J. ROCHE and C. DUMAZERT (Compt. rend. Soc. Biol., 1935, 120, 1225–1227).—The hæmolymp contains glucose (I) and non-fermentable reducing substances pptd. by Cd(OH)<sub>2</sub>. The average content is 0.21 g. per 1000; it is temporarily increased by removal from the aquarium, is unaltered by insulin, adrenaline, or muscular work. R. N. C.

**Hypoglycæmia by conditioned reflex.** C. C. HON and A. RUDEANU (Compt. rend. Soc. Biol., 1935, 121, 185–186).—Rabbits injected with 0.9% daily injections of insulin exhibit a fall of blood-sugar. R. N. C.

**Hourly constancy of phenolæmia in man in normal and pathological states.** R. BANFI, E. L. M., D. MARENZI (Compt. rend. Soc. Biol., 1935, 121, 359).—Free phenols (I) in nephrotoxic blood are > in normal blood, whilst conjugated phenols (II) are more variable. The constancy in normal blood is > that of (II) over a period of 28 hr. P. C.

**Rate of alcohol in the blood in putrefaction in vitro.** NICLOUX (Compt. rend. Soc. Biol., 1935, 120, 1304–1306).—The rate of disappearance

of EtOH from putrefying blood increases with rise of temp. R. N. C.

**Organic phosphorus of the blood studied by the method of prolonged spontaneous hydrolysis, in man and in some domestic animals.** G. DE TONI (Arch. Ist. Biochim. Ital., 1935, 7, 303–340).—The autolysis curves at 37° of org. P in infantile and adult human and animal blood are described. The curves are essentially the same in lactating animals of all species. Autolysis is rapid during the first 24 hr., but slackens very considerably afterwards. In the adult animals inorg. P is always < in the corresponding lactating animals, and the autolysis curves show wide variations from each other. Autolysis is most extensive in rabbit blood, moderate in human and horse blood, whilst sheep's and cows' bloods contain little or no org. P. R. N. C.

**Influence of pituitary body and preparations of other endocrine organs on inorganic salts of the blood.** S. NISHIDA (Sei-i-Kwai Med. J., 1934, 53, No. 6, 133–175).—Hypophysectomy causes a decrease in blood-Cl, -Na, -K, and -Mg and an increase in -Ca. Pituitrin, antuitrin, and pituglandol produce a reciprocal effect in normal dogs and restoration to normal levels in hypophysectomised animals. Oophormin, thyroxine, and adrenaline cause a decrease in Mg and K and an increase in Ca. Insulin produces no change in Mg in normal, but a decrease in that of hypophysectomised, dogs. CH. ABS. (p)

**Blood, bile, and liver of animals with permanent biliary fistulas.** F. CAVAZZA (Pathologica, 1935, 27, 241–250).—In dogs blood-Ca and alkaline reserve are lowered and blood-K increases. No marked changes occur in Ca content of bile and hepatic tissues. CH. ABS. (p)

**Effect of changes in the concentration of plasma-electrolytes on the concentration of electrolytes in the red blood cells of dogs, monkeys, and rabbits.** H. YANNET, D. C. DARROW, M. K. CARY (J. Biol. Chem., 1936, 112, 477–488).—In monkeys and rabbits changes in the plasma-Na, produced by intraperitoneal injection of aq. glucose or NaCl, caused changes in erythrocyte-Na and -K due to shift of H<sub>2</sub>O alone. In the dog a certain migration of cations occurred. H. D.

**Bromine in blood and spinal fluid; its relation to blood-iodine.** U. C. BONORINO, M. SCHTEINGART, and R. FERRAMOLA (Prensa med. Argentina, 1934, Mar. 7).—Blood-Br varied from 0.6 to 3.6 mg. per 100 c.c. Br and I vary in a parallel manner, I:Br ranging between 70 and 170. Spinal fluid contains 0.2 mg. of Br per 100 c.c. CH. ABS. (p)

**Blood-chloride in healthy Koreans.** M. S. KIM (J. Chosen Med. Assoc., 1934, 24, 1537–1540).—Vals. for Koreans who eat excessive amounts of salt fall within normal variations found in occidentals. CH. ABS. (p)

**Effects of hydrochloric acid and sodium hydrogen carbonate administrations on distribution of blood-chlorine.** N. MATSUOKA and K. DAITA (Trans. Soc. Path. Japon., 1934, 24, 82–91).—

$\text{NaHCO}_3$  increases blood-Cl and decreases plasma-Cl. Both vals. increase after administration of HCl.

CH. ABS. (p)

Metabolism of iodine. I. Blood-iodine. II. Influence of ascorbic acid on blood-iodine. H. LOHR (Arch. exp. Path. Pharm., 1936, 180, 332—343, 344—353).—I. Improvements in methods for the micro-determination of I are described. The blood-I (I) of healthy men and women is  $20\text{--}30 \times 10^{-6}\%$  and is not influenced by sex or season; it is greatly increased by exercise (rowing) for 1 hr., returning to normal after 1 hr. rest, but increasing again after 24 hr.

II. Ascorbic acid lowers the (I) of normal and thyroidectomised dogs and antagonises the (I)-increasing action of thyroxine. F. O. H.

Diffusible calcium in the serum of laying and non-laying hens. M. W. TAYLOR and W. C. RUSSELL (J. Agric. Res., 1935, 51, 663—667).—No difference in the level of diffusible Ca was apparent. Non-diffusible Ca was much higher in the laying condition. A. G. P.

Variability of non-haemoglobin iron. T. G. KLUMPP (J. Clin. Invest., 1935, 14, 351—355).—Non-haemoglobin Fe varies widely and is a significant fraction of the total Fe. CH. ABS. (p)

Chemical and physico-chemical sexual differences in the blood of selachians. E. A. PORA (Compt. rend. Soc. Biol., 1936, 121, 105—107).—Corpuscular vol. and Cl, and  $\kappa$  in the blood of males are  $>$  in females, whilst the alkaline reserve is less. The osmotic pressure and inorg. salts in the male are  $>$  in the female in *Scyllium canicula*, but less in *Raia undulata*, whilst with blood-proteins and org. substances of the serum the reverse is the case. R. N. C.

Chemical and physico-chemical sexual differences of the blood of *Labrus bergylla*. E. A. PORA (Compt. rend. Soc. Biol., 1936, 121, 102—105).—The osmotic pressure,  $\kappa$ , blood-, serum-, and corpuscular Cl, serum-Na, and total inorg. substances in the blood of the male are  $>$  in the female, whilst K, Ca, proteins, the alkaline reserve, corpuscular vol., and org. substances are less. The fraction of the osmotic pressure due to NaCl in the male is  $>$  in the female. R. N. C.

Action of indole on hydræmia, chloræmia, and glycaemia. G. F. DE GAETANI (Boll. Soc. ital. Biol. sperim., 1935, 10, 441—443).—Injection of indole in guinea-pigs increases  $\text{H}_2\text{O}$  and depresses Cl in the blood; blood-sugar behaves variably. R. N. C.

Blood-modifications from administration of indole. G. F. DE GAETANI (Boll. Soc. ital. Biol. sperim., 1935, 10, 439—441). R. N. C.

Composition of the blood of some marine invertebrates and vertebrates. E. A. PORA (Compt. rend. Soc. Biol., 1936, 121, 291—293).—From the analytical data given, the osmotic pressure of poikilosmotic marine animals is slightly  $>$  that of the external medium, whilst that of homeosmotic animals is less.  $\kappa$  of the serum of poikilosmotic animals differs from that of the external medium. The % of the osmotic pressure due to NaCl in selachians is

$<$  in teleosts. Blood-Cl in cephalopods is approx. equiv. to Cl in the sea; in selachians it is half, and in teleosts a quarter, of the cephalopod val. Proteins are high in cephalopods. R. N. C.

New antagonistic property of normal sera: the cercaricidal action. J. T. CULBERTSON and S. B. TALBOT (Science, 1935, 82, 525—526).—Sera of many animals have a definite cercaricidal action. L. S. T.

Investigations [on sera] in the ultra-violet. W. GRAUBNER (Z. ges. exp. Med., 81, 1—5; Chem. Zentr., 1934, ii, 3397).—The absorption spectra of different human sera vary considerably, but no significant deviation appears in any single serum. Pptn. with EtOH or dialysis shifts the spectrum about  $10 \text{ m}\mu$  towards the visible, but deproteinisation with  $\text{Fe}(\text{OH})_3$  or large  $p_{\text{H}}$  changes with  $\text{H}_2\text{SO}_4$  or NaOH are ineffective. The substance responsible for the spectrum is not one of the known serum constituents, and probably contains a CO or a  $\text{C}_6\text{H}_6$  ring. Urine always shows a band between 260 and  $280 \text{ m}\mu$ ; the max. is indefinite. The spectra of both sera and urine are probably due to the same substance, which is also present in cerebrospinal and pathological fluids. R. N. C.

Behaviour of calcium in the electrodialysis of blood-serum and its dialysate. G. PERETTI (Boll. Soc. ital. Biol. sperim., 1934, 9, 1333—1336).—Ca transport is anodic with small currents and cathodic with large currents in both serum and its dialysate; this confirms the existence in serum of diffusible non-ionisable Ca complexes. R. N. C.

Calcium metabolism in the first phase of blood clotting. III. Mechanism of thrombin formation. H. SCHEURING (Biochem. Z., 1935, 283, 1—11).—The mechanism of the earlier described (A., 1935, 1263) shift of Ca from the ionised to the negative Ca complex condition during thrombin formation is further investigated. The governing reaction results from the affinity of  $\text{Ca}^{++}$  for prothrombogen (I), the reaction conforming to the mass law and the complex formed being identical with thrombogen (II). The union of thrombokinase (III) with (II) also conforms to the mass law. Normal dog serum contains  $\text{Ca}^{++}$  corresponding with the (II) content, whilst (I) is present in about twice the amount required by the (III) content. P. W. C.

Action *in vitro* of iron-vitamin-C complexes with different bases on the coagulation of blood. F. ARLOING, A. MOREL, and A. JOSSERAND (Compt. rend. Soc. Biol., 1936, 121, 39—41).—Na ascorbate restrains slightly the coagulation of blood *in vitro*. Ferriscorbone complexes with inorg. and org. base exhibit greater restraining action, Ca ferriscorbone being the least anticoagulant. With ferrosorbone the time of coagulation is always  $> 1 \text{ hr.}$  R. N. C.

Influence of splenic fractions on blood coagulation. I. Effect of splenectomy, spleen diet, and spleen extract. S. BOKU, I. HIRAI, and K. GON (J. Chosen Med. Assoc., 1935, 25, 48—50).—Splenectomy accelerates coagulation for 2 days and subsequently delays it. Administration of spleen material restores normal conditions. CH. ABS. (p)

**Mechanism of the action of anticoagulant substances.** H. GOLDIE (Compt. rend. Soc. Biol., 1935, 120, 1181—1185).—The anticoagulant power of compounds of the moranyl group corresponds exactly with, or is slightly  $>$ , the alexin-destroying power; these compounds therefore affect a coagulant agent, probably prothrombin, the structure of which resembles that of alexin (I). Naphthalenesulphonates with high anticoagulant power exert only a feeble effect on (I). The incoagulable plasma exhibits variable characteristics as regards pptn. by acids, and contains "protective colloids." R. N. C.

**Toxicity of ricin and body temperature.** H. MORIYAMA (Japan. J. Exp. Med., 1934, 12, 591—600). CH. ABS. (p)

**Ricin. II.** H. MORIYAMA (Japan J. Exp. Med., 1934, 12, 437—453).—Effects of various substances on the hæmagglutinating power of ricin are recorded. The lyophilic character of the protein is associated with the presence of a double linking, the loss of which causes changes in colloidal state, toxicity, and agglutinating power. CH. ABS. (p)

**Distribution of isoagglutinins in blood-serum fractionated by electrophoresis.** A. GRONWALL (Biochem. Z., 1935, 282, 257—262).—Human serum of individuals of blood group O is fractionated by electrophoresis and the agglutinin titre, protein-N, and precipitability with  $(\text{NH}_4)_2\text{SO}_4$  are determined. Isoagglutinin is distributed uniformly through the fractions pptd. by 30% saturation with  $(\text{NH}_4)_2\text{SO}_4$ . P. W. C.

**Antigenic properties of detoxicated Indian and African venoms: cross-reaction exerted by the respective antivenins.** E. GRASSET and A. ZOUTENDYK (Trans. Roy. Soc. Trop. Med. Hyg., 1935, 391—398; cf. A., 1934, 1022).—Venoms were rendered atoxic by 1%  $\text{CH}_2\text{O}$ . The potency of these preps. is compared with that of African viperine and colubrine venoms. Multivalent antivenins of colubrine venoms may be produced either by unmodified venoms by anavenoms. CH. ABS. (p)

**Toxic and antigenic properties of S. African venoms with special reference to multivalency of S. African antivenin.** E. GRASSET, A. ZOUTENDYK, and A. SCHAAFSMA (Trans. Roy. Soc. Med., 1935, 28, 601—612).—The potency of horse antivenin can be titrated with venoms of the puff adder and Cape cobra. A special evaluation is shown with these venoms and the antivenin. CH. ABS. (p)

**Precipitin reaction to phosphatides of tubercle bacilli.** G. R. DUNCAN, C. C. VAN WAGENINGEN, E. S. MARIETTE, and E. P. K. FENGER (Amer. J. Tuberc., 1935, 31, 307—322).—Human tubercle bacillus (Anderson S-1) does not act as an antigen for precipitation of antibodies in rabbits. S-2 is a very poor and bovine, avian, and lepra phosphatides are good antigens. No type specificity among these phosphatides was apparent. CH. ABS. (p)

**Relation between type-specific carbohydrates of human cord and blood group-specific substances.** F. WITEBSKY, E. NETER, and H. SOBOTKA (J. Exp. Med., 1935, 61, 703—715).—Hæmolysis of

sheep cells is inhibited by human group-sp. A-antiserum. Differences between the acetylated and deacetylated polysaccharides of *Pneumococcus* type I are demonstrated by inhibition of hæmolysis, by complement fixation, and by inhibition of group-sp. isoagglutination tests. Destruction of potency of acetylated polysaccharides by faeces filtrates is not due to fission of Ac. CH. ABS. (p)

**Effect of various enzymes on toxin and anatoxin.** Y. ANAZAWA (Sei-i-Kwai Med. J., 1934, 53, No. 10, 1—62).—Trypsin detoxicates diphtheric and tetanic toxins and destroys their antigenic property. Anatoxins prepared by heating these toxins with  $\text{CH}_2\text{O}$  are not destroyed by trypsin. Neither diastase nor lipase destroys the toxins or anatoxins. CH. ABS. (p)

**Antibody production through the cutaneous route.** Y. HIROSE (Sei-i-Kwai Med. J., 1934, 53, No. 6, 1—73).—The antibody for cholesterol was produced in rabbits by smearing cholesterol or dehydrated lanoline over the skin. CH. ABS. (p)

**Antibody-forming accelerator in spleen. IV. Influence of spleen diet on hæmolysin and agglutinin formation.** S. BOKU, I. HIRAI, and K. GON (J. Chosen Med. Assoc., 1934, 24, 1508—1518).—Splenectiony delays hæmolysin and agglutinin formation. Oral administration of spleen counteracts this effect. CH. ABS. (p)

**Chemical composition of pig's stomach.**—See B., 1936, 168.

**Structure of protoplasm.** W. SEIFRIZ (Bot. Rev., 1935, 1, 18—36). CH. ABS. (p)

**Isoelectric point of mucoproteins.** A. ROCHE (Compt. rend. Soc. Biol., 1935, 120, 1229—1231).—The isoelectric point of the mucoprotein of the submaxillary of the ox is  $p_H$  2.70. R. N. C.

**Isoelectric point of mucoproteins.** A. ROCHE (Compt. rend. Soc. Biol., 1936, 121, 71—73).—The isoelectric points of a no. of mucoproteins from invertebrate tissues are given. That of the vitreous humour is about  $p_H$  3.0, whilst those of the skin are generally higher. R. N. C.

**The myogen volume in relation to the volume of the muscle fibre.** W. HAUMANN and H. H. WEBER (Biochem. Z., 1935, 283, 146—152).—The myogen solution of mammalian muscle occupies 35% of the vol. of the minced muscle and may amount to  $< 20\%$  of the vol. of the intact muscle fibre. Close agreement was obtained by different methods in the determinations of the non-solvent space for myogen. P. W. C.

**Myoglobin. I. Solubility in concentrated ammonium sulphate solutions.** V. E. MORGAN (J. Biol. Chem., 1936, 112, 557—563).—The solubility of carboxymyoglobin (I) in conc. solutions of  $(\text{NH}_4)_2\text{SO}_4$  at  $p_H$  6.6 and  $25^\circ$  is expressed by  $\log S = 8.00 - 0.94(\Gamma/2)$ , where  $S$  is the solubility in g. and  $\Gamma/2$  is the ionic strength per litre. (I) is quite sol. in buffer solutions at  $p_H$  6.6 up to a  $[\text{PO}_4^{''}]$  of  $\approx 3M$ . J. N. A.

**Decomposition of tuberculo-protein, starch, and gelatin by dry grinding.** C. H. BOISSEvain

(Amer. Rev. Tuberc., 1935, 31, 542—546).—Prolonged grinding of starch causes its transformation into erythro-dextrin, and then into achroo-dextrin. Similarly, gelatin is changed to a  $H_2O$ -sol. peptone-like compound incapable of forming a gel even at  $0^\circ$ . Tuberculo-protein (I) is decomposed by grinding into  $H_2O$ -sol. protein, peptone, and polysaccharide. Boiling with dil. acid or treatment with 4% aq. NaOH produces the same change in (I). CH. ABS. (p)

**Factors affecting the affinity of the pulmonary proteins and their degradation products for the lung.** P. MASCHERPA (Boll. Soc. ital. Biol. sperim., 1935, 10, 459—461).—The proteins of the portion of the lung juice expelled by 400 atm. pressure are able to fix Co and convey it to the lungs, the effect being unaffected by tryptic digestion. The effect is not shared by aq. lung extracts or the proteins of the juice expelled by 200 atm. pressure. R. N. C.

**Relation of protein coagulation to oxidation-reduction potential.** Y. NAKAMURA (J. Agric. Chem. Soc. Japan, 1935, 11, 1101—1104).—Treatment of ov- and serum-albumin by heat or ultra-violet irradiation and of milk by enzyme action lowers the potential, indicating a relation between coagulation and hydrolysis. F. O. H.

**Hydrogen-ion dissociation curve of the crystalline albumin of the hen's egg.** R. A. KEKWRICK and R. K. CANNAN (Biochem. J., 1936, 30, 227—234).—The  $H^+$  dissociation curve of ovalbumin has been constructed. The  $H^+$ -combining capacity reaches a max. of 30—32 eqvs. per mol. just below  $p_H$  2. Evidence of a max. dissociating capacity was observed at  $p_H$  8—9 (corresponding with a dissociation of 11 eqvs. of  $H^+$  per mol.), but not at  $p_H$  11.5—12.0. H. G. R.

**Effect of formaldehyde on the hydrogen-ion dissociation curve of ovalbumin.** R. A. KEKWRICK and R. K. CANNAN (Biochem. J., 1936, 30, 235—240).— $H^+$  dissociation curves of ovalbumin (I) in presence of  $CH_2O$  indicate the presence of 16—18  $NH_2$  groups, other than  $\alpha-NH_2$ , which are identified with the  $\epsilon-NH_2$  of lysine. The action of  $HNO_3$  on (I) indicates the presence of 19—20  $NH_2$  groups per mol. and the lysine-N of the phosphotungstate ppt., 17—18 mols. of lysine per mol. H. G. R.

**Relations between some alkaloids and protein substances.** P. MASCHERPA (Boll. Soc. ital. Biol. sperim., 1935, 10, 464—467).—Brucine (I) and strychnine in ovalbumin solutions form non-dialysable complexes with the protein. They also form complexes with serum-proteins, the quantity of alkaloid fixed by ox-serum being > by sheep serum. A method of determining (I) is described. R. N. C.

**Electric cataphoresis of brucine and strychnine in solutions of ovalbumin or in blood-serum from different animals.** P. MASCHERPA (Boll. Soc. ital. Biol. sperim., 1935, 10, 461—464).—Brucine and strychnine in the free state in solutions of ovalbumin or animal sera travel to the cathode, but when bound to the protein they travel to the anode. R. N. C.

**Bioluminescence. II. Partial purification of Cypridina luciferin.** R. S. ANDERSON (J. Gen. Physiol., 1935, 19, 301—305).—The powdered organ-

ism is extracted with MeOH under  $H_2$ , Bu<sup>o</sup>OH is added, the MeOH removed, and the BuOH solution treated with BzCl. Bz or Ac derivatives of luciferin (I) are more stable to  $O_2$  than is (I) itself. Preps. of (I) 2000 times as active as the starting material are obtained, in yields up to 65%, by two benzoylations followed by hydrolysis with  $N-HCl$ . F. A. A.

**Organic bases, especially spermine, in the muscle of higher animals.** K. YOSHIMURA, Y. HIWATASHI, and T. SAKAMOTO (J. Chem. Soc. Japan, 1935, 56, 280—288).—Vals. for creatine, hypoxanthine, carnosine, creatinine, methylguanidine, carnitine, and spermine are given for muscles of cattle, horse, pig, and hen. CH. ABS. (p)

**Antianæmic principle of liver.** H. B. SREERANGACHAR and M. SREENIVASAYA (Current Sci., 1936, 4, 468—472).—A review.

**Hæmatin pigments of Actinia (actiniohæmatin) and cytochrome-b.** J. ROCHE (Compt. rend. Soc. Biol., 1936, 121, 69—71).—The muscle of *Actinia* is rich in cytochrome-b (I), but contains little or no cytochrome-c (II).  $C_5H_5N$  extracts of (II)-free muscles contain protohæmatin and the hæmatin of (II), with traces of that of cytochrome-a. Hence (I) and (II) of *Actinia* contain the same prosthetic group. R. N. C.

**Hæmatin of cytochrome-c and nature of the combination of hæmatins with globins.** J. ROCHE and M. T. BENEVENT (Compt. rend. Soc. Biol., 1935, 120, 1227—1229).—Hæmatin-c (I), the prosthetic group of cytochrome-c (II), shows absorption bands at 614, 568, 535, 498, and 395  $m\mu$ .  $C_5H_5N$  transforms it into a parahæmatin (bands at 578 and 538  $m\mu$ ), which is reduced to a hæmochromogen (bands at 550, 521, and 410  $m\mu$ ) identical with that formed from (II) by  $C_5H_5N$ . (I) and (II) are reduced to the same porphyrin. (I) and natural globin in neutral or slightly alkaline solution form another parahæmatin (bands at 505 and 538  $m\mu$ ), whereas other hæmatins form methæmoglobins. The results suggest that hæmoglobins and hæmochromogens are not formed by the action of the same group in the hæmatin mol. R. N. C.

**Contents of glutathione and vitamin-C in anti-anæmic liver preparations.** F. G. KOSER (Arch. exp. Path. Pharm., 1936, 180, 183—188).—Glutathione does not occur in several (commercial) liver preps., whilst the vitamin-C content varies considerably. F. O. H.

**Glycogen in the central nervous system of human embryos.** O. FUSEJIMA (Sei-i-Kwai Med. J., 1934, 53, No. 9, 80—93).—A histological study. CH. ABS. (p)

**Laracein from the scale of the insect Cero-plastes rubens, Maskell.** R. KOYAMA (J. Chem. Soc. Japan, 1935, 56, 365—372).—The wax from insects grown on tea and on citrus trees had  $n_D^{20}$  0.69694, 0.99208, m.p. 54—56°, 55—57°, sap. val. 152.8, 126.0, acid val. 22.9, 46.6, I val. 76.3, 130.2, respectively. From the wax were obtained, melissic, ceromelissic,  $C_{33}H_{66}O_2$ , m.p. 94°, ceroplastic,  $C_{33}H_{70}O_2$ , m.p. 96—98°, and a resin acid,  $C_{22}H_{34}O_2$ . The unsaponifiable fraction contained ceromelissyl, cero-

plasyll, and melissyll alcohols, all of which are primary. The wax does not contain ceryl or ibotaceryl alcohols or the corresponding acids. CH. ABS. (p)

**Lipin composition and physiological activity in the ovaries of pregnant guinea-pigs.** E. M. BOYD (J. Biol. Chem., 1936, **112**, 591—595).—Ovaries from guinea-pigs at various stages of gestation showed the same average phospholipin content of about 1.25% as those from non-pregnant controls at the pre-ovulatory stage. Similarly there was no significant variation from the mean (0.30%) for the free cholesterol. There is no increase in physiological activity in the ovaries of gravid guinea-pigs. J. N. A.

**Liver-fat and blood determinations after adrenalectomy.** J. F. B. BARRETT and A. T. WILSON (J. Physiol., 1934, **81**, 43—45p).—In doubly adrenalectomised cats increased blood viscosity causes an increase in residual blood in the liver and a consequent fall in the % of total solids. No correlation is apparent between adrenalectomy and the amount and nature of liver-fat. CH. ABS. (p)

**Jaboty fat. Composition of mink fat. New alcohols and hydrocarbons in sperm oil.**—See B., 1936, 158.

**Hexadecenol and tetradecenol in sperm head oil. Hexadecenol in sperm blubber oil.**—See this vol., 311.

**Tetradecenoic and dodecenoic acids in sperm oil.** I, II.—See this vol., 313.

**Change in the solubility of calcium compounds during the autolysis of muscle tissue.** I. A. SMORODINCEV and J. N. LASKOVSKAJA (Bull. Soc. Chim. biol., 1935, **17**, 1814—1821).—The  $H_2O$ -sol. Ca of autolysing beef increases with time in parallel with the lactic acid, but not the  $PO_4^{'''}$  content of the extract. A. L.

**Analysis of otoliths and endolymphatic sac deposits in *Amblystoma tigrinum*.** A. B. HASTINGS (J. Comp. Neurol., 1935, **61**, 295—296).—Saccus deposits and otoliths contained 26.7 and 15.9% of  $Ca_3(PO_4)_2$  as dahlite and 64.5 and 83.2% of  $CaCO_3$  as aragonite, respectively. CH. ABS. (p)

**Role of iron and silica in the structure of the radular teeth of certain marine molluscs.** E. I. JONES R. A. McCANCE, and L. R. B. SHACKLETON (J. Exp. Biol., 1935, **12**, 59—64).—In the *Patellidae* radular teeth consist largely of Si and Fe, the former comprising the skeleton of the teeth. Fe is present as oxide, carbonate, or org. compound. In *Chitonidae* occurs without Si and in *Deutalium* Si, but not Fe, is present. CH. ABS. (p)

**Modifications in the quantity of some phosphorus compounds in the muscle of the pigeon deprived of its cerebellum.** M. F. DE MIRA and DA CRUZ (Compt. rend. Soc. Biol., 1936, **121**, 261).—Extirpation of the cerebellum diminishes inorg. P,  $P_2O_7^{'''}$ , and (particularly) phosphagen. R. N. C.

**Detection of heavy metals in the retina.** E. BARONI (Monatsh., 1935, **67**, 129—130).—Traces of Cu have been found in fresh retina and choroid. Zn is absent. F. L. U.

**Action of lipins on lacteal secretion and the chemical composition of milk. I. Action of lecithin and cholesterol introduced by the parenteral route in the goat. II. Action of the total lipins of egg-yolk introduced by the parenteral route in the goat.** D. TORRISI (Boll. Soc. ital. Biol. sperim., 1935, **10**, 443—445, 445—447).—I. Lecithin (I) in small quantities increases, and in larger quantities reduces, body-wt. and lacteal secretion; small quantities increase total milk-lipins (II) and cholesterol (III). Cholesteryl oleate (IV) increases body-wt., (II), and (III) without affecting secretion. Mixtures of (I) and (IV) in small quantities increase body-wt., lacteal secretion, total, inorg., and casein-P, (II), and (III), without affecting acid-sol. and lecithin-P. Larger quantities reduce body-wt. slightly without affecting lacteal secretion or the composition of the milk.

II. Injection of egg-yolk lipins in well-fed animals increases body-wt., lacteal secretion, total, inorg., and casein-P of the milk, (II), and (III); org. acid-sol. P and kephalin-P are unaffected. In sparingly-fed animals body-wt. and lacteal secretion are diminished, whilst small quantities also diminish (II) and kephalin. A succession of small daily doses influences favourably body-wt., lacteal secretion, (II), and the various P fractions in the milk. R. N. C.

**Monohydroxypalmitic acid in butter fat.** A. W. BOSWORTH and G. E. HELZ (J. Biol. Chem., 1936, **112**, 489—492).—A *monohydroxypalmitic acid*, m.p. 16.5—17.5°,  $[\alpha]_D^{20} +2.40^\circ$  to  $+2.47^\circ$  in  $CHCl_3$ , was separated from butter fat. H. D.

**Biological effects of feeding with the milk of cows in oestrus.** F. USUELLI (Boll. Soc. Eustachiana, 1934, **32**, 57—64; Chem. Zentr., 1934, ii, 3783). R. N. C.

**Detection of oxytocic, pressor, and diuresis-inhibitory components of posterior pituitary secretion in cerebrospinal fluid.** S. DELEONARDI (Arch. exp. Path. Pharm., 1936, **180**, 135—141).—All three components (oxytocic in amount corresponding with approx.  $0.4 \times 10^{-6}$  g. of fresh pituitary prep. per c.c.) were detected in cerebrospinal fluid (rabbit, dog) and in fluid from the second and third ventricles (man). F. O. H.

**Colour reaction of cerebrospinal fluid in cerebrospinal meningitis.** R. REITLER (Trans. Roy. Soc. Trop. Med. Hyg., 1935, **28**, 405—406).—The centrifuged fluid (1 c.c.) is poured over a layer (1 c.c.) of  $H_2SO_4$ . In pathological, but not in normal, fluids a violet ring is produced in 24 hr. CH. ABS. (p)

**Stability of sugar in cerebrospinal fluid.** P. G. SCHUBE (J. Lab. Clin. Med., 1935, **20**, 752—753).—The sugar content of the fluid stored under sterile conditions at  $10^\circ$  remains unchanged for  $\leq 21$  days. CH. ABS. (p)

**Inorganic phosphorus and sugar of cerebrospinal fluid.** P. UJSACHY (Orvosi Hetilap, 1935, **79**, 381—382).—Some proportionality between the two vals. was observed, but no regularities were apparent. The occurrence of high or normal P contents was no indication of the presence or absence of meningitis. CH. ABS. (p)

**Modifications of the thiocyanate concentration of the nasal mucus and other secretions, in relation to stimulation of the trigeminum and the olfactorium.** P. NICCOLINI (Boll. Soc. ital. Biol. sperim., 1935, 10, 431—432).—Stimulation of the olfactorium with eucalyptus oil increases CNS' in the nasal and lachrymal secretions and the urine, but not in the saliva. R. N. C.

**Saliva.** A. CASTELLANI, M. DOUGLAS, P. REDAELLI, and G. AMALFITANO (J. Trop. Med. Hyg., 1935, 38, 81—87).—A review. CH. ABS. (p)

**Presence of lactic acid in the saliva.** R. VLADESCO (Compt. rend. Soc. Biol., 1936, 121, 275—276).—Lactic acid is always present. R. N. C.

**Hæmolytic actions and surface tension of human and animal biles and cholates.** S. TSUJI (Japan. Z. Mikrobiol. Path., 1934, 28, 1534—1552).—Among various biles examined those of carp and toads had the greatest hæmolytic action and that of chicken the highest surface tension. CH. ABS. (p)

**Action of post-pituitary extracts on gastric secretion.** L. LANGERON, M. PAGET, and A. DANES (Compt. rend. Soc. Biol., 1936, 121, 33—35). R. N. C.

**Gastric acidity and its significance.** F. L. APPERLY (Lancet, 1936, 230, 5—9). L. S. T.

**Urine of the normal cat.** L. BLANCHARD (Bull. Soc. Chim. biol., 1935, 17, 1693—1706).—The vol., acidity, and urea,  $\text{NH}_3$ , and Cl' content of the urine of the cat are 37 c.c. per kg. wt. per day, 0.060 g. of H, 84.10—89.85, 1.88—2.69, and 3.05—4.67 g. per 1000 g., respectively. The normal urine contains albumin (0.5 g. per 1000 g.), and under certain conditions of feeding small amounts of lipins and cholesterol. A. L.

**Modifications of the urinary reaction following renal denervation.** E. TRIA and B. CAPALDI (Boll. Soc. ital. Biol. sperim., 1935, 10, 502—504).—Renal denervation induces a fall of the actual and potential acidity of the urine, a slight rise in  $\text{NH}_3$ , and a considerable rise of combined  $\text{CO}_2$ , free  $\text{CO}_2$  being scarcely affected. Conditions tend to return to normal after 10—15 days. R. N. C.

**Partition of nitrogenous constituents of urine and its physiological significance. VII. Evolution of specific endogenous nitrogen metabolism during protein inanition.** G. MOUROT (Bull. Soc. Chim. biol., 1935, 17, 1741—1789).—In the urine of rats undergoing protein starvation, the total N, after remaining nearly const. for some time, increases before death. Whilst urinary creatinine, uric acid, and purine bases do not, the urea-,  $\text{NH}_3$ -, and  $\text{NH}_2\text{-N}$ , allantoin, and creatine losses do, follow the same course as that of the total N. A. L.

**Detection of leucine and tyrosine [in urine].** FISCHER and H. STRALLER (Pharm. Ztg., 1936, 81, 38—39).—A method is given for detecting 0.01% of leucine (I) and tyrosine (II) in urine. In fresh urine containing sediment, (I) and (II) are in the sediment and not in solution. Control tests are advisable when the microscopic test is used. (I) and (II) occur very rarely in urine. P. G. C.

**Micro-determination of trimethylamine in the urine.** G. MONASTERIO (Boll. Soc. ital. Biol. sperim., 1935, 10, 385—386).—The urine is distilled with alkaline  $\text{NaOCl}$ , which decomposes all but the *tert.* bases.  $\text{NMe}_3$  is collected in 0.02N- $\text{H}_2\text{SO}_4$  and excess of  $\text{H}_2\text{SO}_4$  determined with I. R. N. C.

**Histidine in human urine.** F. FOLDES (Biochem. Z., 1936, 283, 199—209).—The frequency of the occurrence of histidine (I) in human urine increases as its *d* increases. (I) is detected more frequently in the urine of pregnant women than in that of non-pregnant, but a test for pregnancy cannot be based on this difference. No (I) could be detected in the urine of non-pregnant animals (dog, horse, cow, elephant, giraffe, tiger, antelope). A method described is more sensitive for the detection of (I) than is that of Kapeller-Adler (A., 1934, 1050). W. McC.

**Renal innervation and reducing substances in the urine.** E. MARTINI, A. BONSIGNORE, and F. PINOTTI (Boll. Soc. ital. Biol. sperim., 1935, 10, 474—477).—The oxidised/reduced ascorbic acid ratio in the urine of the dog is increased by congelation of the vagi, renal denervation, or injection of atropine. It is reduced by excitation of the congealed vagi or injection of eserine. R. N. C.

**Determination of ascorbic acid in urine by titration.** H. VON EULER and D. BURSTROM (Biochem. Z., 1935, 283, 153—157).—The ascorbic acid contents of the same samples of urine as determined by the Bezssonoff method (using molybdophosphotungstic acid) are always very much > results on the same urines by the Tillmans method. P. W. C.

**Use of Mayer's reagent for detection of quinine in alkaline urine.** J. W. FIELD and M. KANDIAH (Trans. Roy. Soc. Trop. Med. Hyg., 1935, 28, 385—390).—Addition of  $\text{AcOH}$  to the reagent ensures pptn. of albumin (I), and of quinine (II) in clinically significant amounts. If (I) is present, urine and reagent are boiled and filtered while hot. On cooling (II) is pptd. CH. ABS. (p)

**Detection of acridine derivatives in urine.** G. FERRARI (Diagnostica tec. lab. [Napoli], 1934, 5, 928—932).—The sample (5 c.c.) is treated with 1—2 drops of 20% aq. Na caffeine benzoate. An intense green fluorescence or the enhanced intensity of an existing fluorescence indicates the presence of acridine derivatives. CH. ABS. (p)

**Determination of urinary ketones for clinical use.** E. MACCHIA (Diagnostica tec. lab. [Napoli], 1934, 5, 908—918).—An application of the nitroprusside reaction is described. CH. ABS. (p)

**Paraffin hydrocarbon from urine of pregnancy.** W. F. HART and M. A. NORTHUP (J. Amer. Chem. Soc., 1935, 57, 2726—2727).—The material extracted by light petroleum from the adsorbate (fuller's earth) from the acidified, aged urine is separated by warm MeOH into insol. *heptacosane*, m.p. 58—59°, and (probably) sol. *pentacosane*, m.p. 52—54°. H. B.

**Urinolysis in fat metabolism.** F. J. JIRKA and C. S. SCUDERI (J. Lab. Clin. Med., 1935, 20, 631—633).—Intracystic fat occurs exclusively in the last

few drops of urine excreted. It may be determined directly by centrifuging in a Babcock bottle.

CH. ABS. (p)

**Determination of glucose and chlorides in urines containing sodium formaldehydesulphoxylate.** E. HUG and R. H. DE MEIO (Compt. rend. Soc. Biol., 1936, 121, 370—372).—Na formaldehydesulphoxylate reduces  $\text{AgNO}_3$  and alkaline Cu solutions, and must be oxidised with  $\text{HNO}_3$  and  $\text{KMnO}_4$  before Cl<sup>-</sup> can be determined. Glucose can be determined polarimetrically, or by Cu after preliminary deproteinisation with  $\text{HgSO}_4$ — $\text{H}_2\text{SO}_4$  and  $\text{BaCO}_3$ , and removal of Hg with  $\text{H}_2\text{S}$ .

R. N. C.

**Enteric coatings. II. Excretion studies with sodium salicylate tablets.** M. WRUBLE (J. Amer. Pharm. Assoc., 1935, 24, 1074—1077).—The amounts of salicylate recovered from the urine by a modified Thoburn-Hanzlik method were approx. the same whether coated or uncoated tablets of Na salicylate were administered.

E. H. S.

**Approximate rapid determination of the barbital content of urine and drugs.** H. OETTEL (Arch. Pharm., 1936, 274, 1—10).—The barbital content of urine is determined within a few mg. by acidifying 10 c.c. with a few drops of 0.1N-HCl, extracting with 20 c.c. of  $\text{CHCl}_3$ , and adding small amounts of 0.2%  $\text{MeOH-Co(OAc)}_2$  and 0.2%  $\text{MeOH-LiOH}$  to the extract. Barbitals are detected in urine immediately and several days after administration.

R. S. C.

**"Donaggio phenomenon" in the urine of children affected with muscular dystrophy both at rest and after fatigue.** E. BOZZI (Boll. Soc. ital. Biol. sperim., 1935, 10, 586—587).

R. N. C.

**"Donaggio phenomenon" in the urine of horses in febrile conditions.** P. RUCCI BITTI (Boll. Soc. ital. Biol. sperim., 1935, 10, 561—563).

R. N. C.

**"Donaggio reaction" in the urine of fatigued individuals.** A. TORBOLI (Boll. Soc. ital. Biol. sperim., 1935, 10, 548—550).

R. N. C.

**"Inhibition phenomena" of Donaggio.** T. ITALI (Diagnostica tec. lab. [Napoli], 1935, 6, 9—20).

CH. ABS. (p)

**Microdetermination of the  $p_H$  of fluid in renal glomeruli and tubules.** H. MONTGOMERY and A. PIERCE (Amer. J. Med. Sci., 1934, 187, 735).—A colorimetric method for 0.2-c.c. samples and a quinhydrone electrode for 0.02 c.c. are described. Vals. for glomerular, proximal, and intermediate tubular fluids in *Necturus* are the same as that for plasma. The  $p_H$  decrease occurs in the distal tubule, in which vals. are always < that of glomerular fluid and > that of the corresponding urine.

CH. ABS. (p)

**Determination of total lipins and lipin partition in faeces.** H. C. TYDWEIL and L. E. HOLT, jun. (Biol. Chem., 1936, 112, 605—613).—A method for determining the partition of lipins, unsaponifiable matter, neutral fat, fatty acid, and soap in a single sample is described.

J. N. A.

**Calcium precipitation in the pancreas.** M. EPER, A. LESURE, E. BIOY, and P. PERREAU

(Compt. rend. Soc. Biol., 1936, 121, 22—24).—Pancreatic Ca is 2—5 times as great as hepatic Ca in pathological states, which is probably the cause of its rapid petrification.

R. N. C.

**Blood and urinary phosphorus in various diseases.** T. IMIO (J. Chosen Med. Assoc., 1935, 25, 26—40).—Data are recorded.

CH. ABS. (p)

**Carbon disulphide and adrenals (Addison's disease).** L. DEVOTO (Arch. Gewerbepath. Gewerbehyg., 1934, 5, 429—432).—A case is reported of Addison's disease following prolonged work with  $\text{CS}_2$ .

R. N. C.

**Prophylaxis of simple anaemia in infancy with iron and copper. Effect on haemoglobin, weight, and resistance to infection.** S. J. USHER, P. N. MACDERMOT, and E. LOZINSKI (Amer. J. Dis. Children, 1935, 49, 642—657).—Daily administration of  $\text{Fe}^{III}$  glycerophosphate to infants increased the average haemoglobin concn. at 1 year by 15%. Simultaneous administration of  $\text{CuSO}_4$  enhanced the effect, and increased gains in wt. and resistance to infection.

CH. ABS. (p)

**Glutathione and anaemia.** G. C. DOGLIOTTI and T. CASTELLANI (Boll. Soc. ital. Biol. sperim., 1935, 10, 521—523).—Total glutathione (I) in the blood is normal or slightly reduced in post-haemorrhagic or acute infectious anaemia, whilst corpuscular (I) is normal or slightly raised. In other anaemias total (I) is generally normal, whilst corpuscular (I) is raised; in polycythemia corpuscular (I) is reduced.

R. N. C.

**Further evidence for the presence of a toxic factor in pernicious anaemia.** G. E. WAKERLIN and H. D. BRUNER (Science, 1935, 82, 494—495).—The urine contains a thermolabile, comparatively toxic, reticulocyte-decreasing factor and a partly thermostable, relatively non-toxic, reticulocyte-stimulating principle for the pigeon. Normal human urine contains the latter, but not the former.

L. S. T.

**Non-identity of lactoflavin and the "extrinsic factor" in pernicious anaemia.** C. A. ASHFORD, L. KLEIN, and J. F. WILKINSON (Biochem. J., 1936, 30, 218—223).—Lactoflavin is not identical with either the liver anti-pernicious anaemia principle or the "extrinsic factor."

H. G. R.

**Effect of transfusion of heterogeneous formalised blood in experimental acetylphenylhydrazine anaemia in the rabbit.** O. MALAGUZZI-VALERI (Boll. Soc. ital. Biol. sperim., 1935, 10, 453—455).

R. N. C.

**Effect of heterogeneous formalised transfusion in experimental anaemia from bleeding in the rabbit.** O. MALAGUZZI-VALERI (Boll. Soc. ital. Biol. sperim., 1935, 10, 546—548).

R. N. C.

**Cholesterol content of plasma in arthritis.** E. F. HARTUNG and M. BRUGER (J. Lab. Clin. Med., 1935, 20, 675—681).—Plasma-cholesterol (I) decreased in rheumatoid and increased in osteo-arthritis. The ratio of free (I) : (I) esters is normal. Total (I) of the blood and sedimentation rate are not related.

CH. ABS. (p)

**Cholesterol-induced atherosclerosis: prevention in rabbits by feeding an organic iodine compound.** I. H. PAGE and W. G. BERNHARD (Arch. Path., 1935, 19, 530—536).—Administration of org. I compounds prevents atherosclerosis following feeding of cholesterol (I) in olive oil. Persistent lipæmia also occurring under these conditions is more marked when I compounds are given. The lipæmia differs from that occurring in nephrosis, in that total, free, and ester-(I) are increased relatively  $>$  are lipin-N,  $\text{-NH}_2\text{-N}$ , or  $\text{-P}$ . CH. ABS. (p)

**Separation of liver substances which are reticulocytogenic in the guinea-pig and therapeutically active in experimental canine black tongue.** Y. SUBARROW, B. M. JACOBSON, and C. H. FISKE (New England J. Med., 1935, 212, 663—664).—Approx. 50% of the activity of crude liver extract was due to *l*-tyrosine. A second active substance can be adsorbed on charcoal and eluted by EtOH. CH. ABS. (p)

**Serum-proteins in cancer.** W. KOPACZEWSKI (Compt. rend., 1935, 201, 1229—1231).—In cancer serum-globulin and -albumin are  $<$  and myxoproteins  $>$  normal. The hydrophobic colloid content, and the physical condition of the colloid, are concerned in the acceleration of lactogelatinisation of cancerous sera. A. G. P.

**Schubert-Dannmeyer test for cancer.** E. R. HOLIDAY and F. C. SMITH (Amer. J. Cancer, 1935, 23, 339—342).—The method, based on changes in serum-lipin in cancer, is not sufficiently trustworthy for clinical use. CH. ABS. (p)

**Early diagnosis of carcinoma by exact chemical measurement.** R. LINKS (Z. Krebsforsch., 1934, 41, 166—206; Chem. Zentr., 1934, ii, 3787—3788).—A formula is given for the diagnosis of carcinoma from serum-K and -Mg determinations. R. N. C.

**Inhibiting the development of tar-carcinoma in mice.** J. R. DAVIDSON (Canad. Med. Assoc. J., 1935, 33, 364—366).—A diet rich in vitamin-E and incidentally in  $\text{-B}_1$  and  $\text{-B}_6$  increased the resistance of mice to carcinogenic factors in tar. CH. ABS. (p)

**Carcinogenic action of 1:2-benzpyrene.** C. SANNIE, C. OBERLING, M. GUERIN, and P. GUERIN (Compt. rend. Soc. Biol., 1935, 120, 1196—1198). R. N. C.

**Physiological validity of enzyme [amylase] determinations in tumour tissue.** F. H. SCHARLES, P. ROBB, and W. T. SALTER (Amer. J. Cancer, 1935, 23, 322—327).—The method previously described (A., 1934, 1023) determines only the enzymic activity, and not the effect of accelerators or inhibitors. CH. ABS. (p)

**Plasma and erythrocyte glutathione in human cancer.** J. W. SCHOONOVER (Amer. J. Cancer, 1935, 23, 315—321).—In cancer the ratio of oxidised glutathione (I) to reduced (I) is increased in plasma and lowered in erythrocytes. The quotient of the ratio in plasma  $\div$  the ratio in erythrocytes is  $>$  normal. CH. ABS. (p)

**Blood-glutathione in human cancer.** J. W. SCHOONOVER (Amer. J. Cancer, 1935, 23, 311—314).—

The average concns. of oxidised and of reduced glutathione (I) remain normal in cancer, but vals. for reduced (I) in erythrocytes were slightly  $>$  normal. CH. ABS. (p)

**Aminoethyl phosphate from tumours.** E. L. outhouse (Biochem. J., 1936, 30, 197—201).—Bovine malignant tumours contain aminoethyl phosphate (I) [*Ba* salt; *brucine* salt (one equiv. of brucine); *flavianate*, m.p. 223°] identical with synthetic (I) from aminoethanol (II) phosphate and  $\text{POCl}_3$ . Hydrolysis of (I) with phosphatase gives (II) (flavianate, m.p. 198° and 212°). Probably the formula of (I) is  $\text{CH}_2\text{<NH}_3\text{O>PO-OH}$ , at least at  $p_H$  5—9. W. McC.

**Biodynamics of the pseudo-proteins. Chemotherapy of carcinoma by redox substances from osteocolla.** O. HUPPERT (Wien. med. Woch., 1934, 84, 624—628; Chem. Zentr., 1934, ii, 3788).—A thiogelatin, an org. Fe-heavy-metal complex with a synthetically-introduced thiazole-glyoxaline group of the character of glutathione, prepared from osteocolla, has an inhibitory effect on growth of *B. coli*, and is thus a possible therapeutic agent for cancer. R. N. C.

**Effect of bromohexic acid on rat sarcoma 39.** W. A. SELLE and M. BODANSKY (Amer. J. Cancer, 1935, 23, 289—296).—No sp. inhibition of growth was observed. CH. ABS. (p)

**Enzymes in rabbit sarcoma.** K. MIYAMA (Sei-Kwai Med. J., 1934, 53, No. 6, 105—123).—Necrotic and non-necrotic areas in rabbit sarcoma contain amylase and lipase, the latter being greater in necrotic sections. The lipase is resistant to atoxyl and quinine. Small amounts of trypsin and a pepsin-like enzyme occur in both areas. CH. ABS. (p)

**Dental caries. III. Rickets in relation to caries in deciduous and in permanent teeth.** A. F. HESS, H. ABRAMSON and J. M. LEWIS (Amer. J. Dis. Children, 1934, 47, 477—487). CH. ABS. (p)

**Mottled enamel in Texas.** H. T. DEAN, R. M. DIXON, and C. COHEN (U.S. Publ. Health Repts., 1935, 50, 424—442).—A review. CH. ABS. (p)

**Calcium and phosphorus metabolism of children with mottled enamel.** E. M. LANTZ, M. C. SMITH, and R. M. LEVERTON (J. Home Econ., 1935, 27, 236—239).—The Ca and P metabolism is not affected by feeding F. F probably causes mottled enamel by a sp. effect on the enamel-forming organ. CH. ABS. (p)

**Changes in teeth and bone in chronic fluoride poisoning.** C. J. SUTRO (Arch. Path., 1935, 19, 159—173).—Changes in the enamel and bone matrix caused by feeding NaF are due to chemical disturbances unrelated to the parathyroid glands. CH. ABS. (p)

**Glutathione and diabetes.** G. C. DOGLIOTTI and O. MELONI (Boll. Soc. ital. Biol. sperim., 1935, 10, 523—525).—Total glutathione (I) in the blood of diabetics is normal whether or not insulin (II) has been administered. Corpuscular (I) is slightly  $>$  normal in moderate diabetes, and slightly  $<$  normal after (II); it is also  $<$  normal in severe cases. R. N. C.

**Diabetes mellitus, its differentiation into insulin-sensitive and insulin-insensitive types.** H. P. HIMSWORTH (Lancet, 1936, 230, 127—130).—One type appears to be caused by a deficiency of insulin (I), and the other to lack of an unknown factor which sensitises the body to (I). L. S. T.

**Effect of protein on carbohydrate tolerance of two patients having combined diabetes mellitus and pernicious anaemia.** N. JOLIFFE, H. BRANDALEONE, and H. MOST (J. Clin. Invest., 1935, 14, 357—365).—High-protein (II) diets reduced carbohydrate (I) tolerance. Use of high-(I) diets counteracted the immediate effects of (II), but loss in tolerance was permanent and not affected by insulin. CH. ABS. (p)

**Absorption curve of glucose by the red corpuscles of normal and diabetic subjects *in vitro*.** G. PATRASSI and U. TEODORI (Boll. Soc. ital. Biol. sperim., 1935, 10, 527—528).—The absorption curves of the corpuscles are very similar in the two cases, both rising to a steady max., the increases of the glucose contents being equal. R. N. C.

**Relations between bilirubinaemia and carbohydrate metabolism. I. Bilirubinaemia in fasting and glucose-fed diabetics.** E. SLAVICH (Boll. Soc. ital. Biol. sperim., 1935, 10, 531—532).—Bilirubinaemia in diabetics is considerably > normal. It is not affected by ingestion of glucose. R. N. C.

**Effect of thyroidectomy in poisoning by diphtheria toxin.** P. LOCATELLI (Boll. Soc. ital. Biol. sperim., 1934, 9, 1317—1318). R. N. C.

**Influence of acute infection and artificial fever on plasma-lipins.** A. V. STOEßER and I. McQUARRIE (Amer. J. Dis. Children, 1935, 49, 658—671).—Plasma-lipins decrease in acute febrile, but not in afebrile, disorders or induced fevers. Fever, in itself, does not cause lipin changes. CH. ABS. (p)

**Experimental goitre: functional, chemical, histological studies.** C. A. HELLWIG (Arch. Path., 1935, 19, 364—371).—A Ca-rich diet induces goitres in rats. The I content of goitres is related to that of the diet. Colloid (I-rich) goitres have a higher thyroid function than do parenchymatous, colloid-rich goitres. The latter induce the higher blood-Ca vals. CH. ABS. (p)

**Etiology of enzootic bovine haematuria. I.** A. DATTA (Indian J. Vet. Sci., 1934, 4, 341—344).—Oral administration of Ca lactate or intramuscular injection of  $\text{CaCl}_2$  caused no appreciable difference in coagulability of blood in affected cases. Serum-Ca was not affected, but serum- $\text{PO}_4^{'''}$  increased. CH. ABS. (p)

**Index and jaundice of the newborn.** H. HOLLÓSI and Z. HORVÁTH (Amer. J. Dis. Child., 1935, 49, 638—641).—The haemoglobin index is > 100% in normal and < 100% in jaundiced newborn. CH. ABS. (p)

**Ureum-phosphatase in toxic and haemolytic jaundice.** A. R. ARMSTRONG and E. J. KING (Canad. J. Biochem. Physiol., 1935, 32, 379—383; cf. A., 1935, 403).—The phosphatase increased markedly in toxic, but not in haemolytic, jaundice. CH. ABS. (p)

**Significance of thiocyanate in hepatic coma.** H. INOUE (J. Chosen Med. Assoc., 1934, 24, 1355—1365).—The  $\text{SCN}^-$  in blood and urine is lowered in hepatic coma. Vals. were also low in rabbits with total biliary obstruction and in dogs with Eck fistula. CH. ABS. (p)

**Pathological physiology of the liver. III. Impaired function in relation to nitrogen-containing substances.** I. MATSUO and K. INOUE (Acta Schol. Med. Kioto, 1935, 17, 417—432).—A review. CH. ABS. (p)

**Role of fats and cholesterol in the Henry reaction.** V. CHORINE (Compt. rend. Soc. Biol., 1936, 121, 297—300).—The intensity of the Henry reaction is reduced by washing the serum with  $\text{Et}_2\text{O}$ , which reduces surface tension and removes fats and cholesterol. The reaction is associated with protein modifications in the serum, the role of fats and cholesterol being secondary. R. N. C.

**Lipins and melano-flocculation (Henry reaction).** F. TRENSZ (Compt. rend. Soc. Biol., 1935, 120, 1268—1270).—The euglobulins of paludic sera that have been freed from fat by pptn. with  $\text{COMe}$ , no longer give positive melano-flocculation reactions. The isolated globulins also lose their melano-flocculability when treated with  $\text{COMe}_2$ ; the reaction is therefore dependent not on the protein part of the globulin mol., but on associated lipins or other  $\text{COMe}_2$ -influenced substances. R. N. C.

**Chemical factors of malaria-flocculation (Henry reaction) in anophelian paludism.** E. BENHAMOU and R. GILLE (Compt. rend. Soc. Biol., 1935, 120, 1259—1261).—The three factors controlling malaria-flocculation are euglobulin, serin, and cholesterol; the Henry reaction depends on their ratio (the index of flocculability), but not on any of them separately. R. N. C.

**Melano-precipitation serological reaction in malaria.** E. D. W. GRIEG, C. O. VAN ROOYEN, and E. B. HENDRY (Trans. Roy. Soc. Trop. Med. Hyg., 1934, 28, 175—191).—The substitution of a colloidal melanin (I) solution (prep. described) for the ox-choroid antigen (Henry) is suggested. In the course of a benign tertian infection the blood-phospholipin inversely  $\propto$  the reacting titre with (I). CH. ABS. (p)

**Malaria and blackwater fever. I. Malaria. II. Blackwater fever. Haemoglobinæmia. III. New blood pigment in blackwater fever and other biochemical observations.** N. H. FAIRLEY and R. J. BROMFIELD (Trans. Roy. Soc. Trop. Med. Hyg., 1933—1934, 27, 289—314).—I. Blood destruction in malaria is associated with hyperbilirubinaemia, urea increase, decrease in blood-cholesterol, and normal alkali reserve. Haemoglobinæmia does not occur. Sp. treatment (quinine etc.) decreases plasma-bilirubin and -urea and increases blood-cholesterol.

II. In blackwater fever blood is brownish-red and contains methaemoglobin (I). Washed red cells do not contain (I). Variations in (I) and oxyhaemoglobin (II) are recorded. (I) arises from (II) which has been liberated from corpuscles after lysis. Drug-methaemoglobinæmia is intracorpuseular in origin and does not

involve presence of (I) in plasma or excretion in urine.

III. The pigment resembles but is not identical with (I). The hæmolytic agent in blackwater fever arises from metabolic breakdown in chronic subtertian malarial infection, is pptd. by quinine, lysing the corpuscle and converting the liberated (II) into (I), or the new pigment. CH. Abs. (p)

**Function of the liver in malaria. Overloading with galactose and combined overloading with insulin-glucose-water.** K. TSCHELOV and I. MLADENOV (Arch. Schiffs- u. Tropen-Hyg., 1934, 38, 282—287; Chem. Zentr., 1934, ii, 3405).—Galactosuria following overloading with galactose does not indicate liver injury. In some patients blood-sugar (I) is increased without sugar excretion. Combined administration of glucose and  $H_2O$  after insulin produces a disturbance of the liver function, with hypoglycæmia and an abnormal difference between (I) in the unaffected and hypoglycæmic states. (I) is frequently delayed in reaching its max. R. N. C.

**Experimental chemotherapy in malaria.** W. KIKUTH (Deut. med. Woch., 1935, 61, 573—577). R. N. C.

**Chlorine metabolism in meningitis.** A. PRUNELL (Prensa med. Argentina, 1935, No. 2).—Bacillary meningitis is usually followed by decreased  $Cl'$  in spinal fluid; glucose content is lowered and fibrin is present. Blood- $NaCl$  is correspondingly decreased. CH. Abs. (p)

**Diagnostic and prognostic significance of the creatine-creatinine metabolism in various myopathies before and after amino-acid therapy.** H. H. BEARD, C. J. TRIPOLI, and J. E. ANDES (Amer. J. Med. Sci., 1934, 188, 706—712).—Clinical improvement is associated with increased creatine excretion (50—200% > that of control period) provided this increased creatinuria soon disappears or returns to the control level. Creatinuria probably has an exogenous origin from the  $NH_2$ -acids of the diet. CH. Abs. (p)

**Thiocyanate ions in blood and urine of nephritic cases.** H. INOUE and M. YAMASHITA (J. Chosen Med. Assoc., 1935, 25, 1—13).—Blood- $SCN'$  increases and urinary  $SCN'$  decreases in nephritis. A similar retention of  $SCN'$  occurs in experimental nephritis produced in rabbits by cantharidin, U, and  $HgCl_2$ . CH. Abs. (p)

**Phenol contents of blood of nephritic and hepatic patients.** D. YANAGIHARI (J. Chosen Med. Assoc., 1934, 24, 1562—1570).—Vals. for free, combined, and total  $PhOH$  in nephritic patients were <, and in hepatic patients >, normal. The free  $PhOH$  in blood increases with the gravity of the disease. No relationship was apparent between blood pressure and blood- $PhOH$ . CH. Abs. (p)

**An optimal diet in promoting nitrogen gain in nephrosis** S. H. LIU and H. I. CHU (J. Clin. Invest., 1935, 14, 293—303).—In Bright's disease of the nephrotic type, N retention was favoured by increasing the carbohydrate, fat, and N in the diet. Optimum

vals. are given. Changes in serum-protein level took place slowly even during N retention.

CH. Abs. (p)  
**Indican test on blood and urine in renal insufficiency.** S. H. POLAYES and E. A. ECKERT (J. Lab. Clin. Med., 1935, 20, 681—688).—High blood-indican (I) is always accompanied by high total non-protein-N (II). In some cases of severe renal disease normal (I) occurs with high (II). A persistent increase in (I), concomitant with a decrease in urinary indican, indicates a fatal prognosis. CH. Abs. (p)

**Influence of glycine on creatinuria in peripheral neuritis.** M. J. C. ALLISON, H. H. HENSTELL, and H. E. HIMWICH (Amer. J. Med. Sci., 1934, 188, 560—564).—Ingestion of glycine markedly increased creatinuria. Edetan and glutamic acid had no action. CH. Abs. (p)

**Nutritional oedema in the dog. II. Hypoalbuminaemia and the augmentation of tissue fluid.** A. A. WEECH, E. GOETTSCHE, and E. B. REEVES (J. Exp. Med., 1935, 61, 717—734).—Data relating to N metabolism and wt. changes indicate increasing retention of fluid during the pre-oedema stage. A positive correlation between the duration of oedema and the protein content of the oedema fluid is not demonstrable. CH. Abs. (p)

**Polypeptidæmia in pellagra.** P. TOMESCO, N. G. IONESCO, and P. CONSTANTINESCO (Compt. rend. Soc. Biol., 1936, 121, 190—192).—Polypeptidæmia is increased in pellagra, particularly in the more pronounced visceral forms. R. N. C.

**Behaviour of hepatic lipins in experimental rabies.** R. MACCOLINI (Boll. Soc. ital. Biol. sperim., 1935, 10, 580—583).—Hepatic lipins are > normal in the rabbit. R. N. C.

**Action of the lung on polypeptides: application to the study of scalds.** L. BINET and M. BURNSTEIN (Compt. rend. Soc. Biol., 1936, 121, 287—289).—Perfusion of blood through an isolated scalded lung causes an increase in the polypeptide content of the blood, which is reduced by subsequent perfusion through a normal lung. R. N. C.

**Chemotherapy of schistosomiasis.** M. KHALIL (J. Egypt Med. Assoc., 1935, 18, 284—295). CH. Abs. (p)

**Experimental scurvy. XX. Leucocytes in blood of guinea-pigs on a vitamin-C-free diet. XXII. Amounts of reducing substance and hydrolysed sugar in urine of guinea-pigs on a vitamin-C-free diet.** J. SHIMADA. XXIV. Gas metabolism. Y. SONEDA and Y. KATO (Sei-i-Kwai Med. J., 1934, 53, No. 6, 105—123, No. 10, 159—171, 172—186).—XXII. Scurvy does not affect the reducing substances in urine. Partial inanition causes a decrease in the amount and % of these substances.

XXIV Diets free from vitamin-C cause an initial decline (2 days), a return to normal (3 days), and from the tenth scorbutic day till death a steady decline in gaseous metabolism. The  $O_2$  intake of semi-starved guinea-pigs is reduced in abs. val., but practically unchanged if calc. on a body-wt. basis. CH. Abs. (p)

Complement fixation as related to resistance and allergy in experimental tuberculosis. A. B. BAKER (Amer. Rev. Tuberc., 1935, 31, 54—61).  
CH. ABS. (p)

Gastric acidity in pulmonary tuberculosis. I. GRAY and J. MELNICK (Amer. Rev. Tuberc., 1935, 31, 460—465).  
CH. ABS. (p)

Vitamin therapy in intestinal tuberculosis. M. M. STEINBACH and M. B. ROSENBLAT (Amer. Rev. Tuberc., 1935, 31, 35—43).—High-vitamin diets neither cured nor prevented intestinal tuberculosis.  
CH. ABS. (p)

Effect of applications of irradiated cholesterolised lanoline on the blood-cholesterol in pulmonary tuberculosis. A. DUFOUR and P. LAROUX (Compt. rend. Soc. Biol., 1936, 121, 43—45).  
R. N. C.

Standardised tuberculin (purified protein derivative) for uniformity in diagnosis and epidemiology. E. R. LONG, F. B. SEIBERT, and J. D. ARONSEN (Tubercle, 1935, 16, 304—322).  
CH. ABS. (p)

Old tuberculin, human tubercle bacillus protein, and trichloroacetic acid precipitate. C. A. STEWART (Amer. J. Dis. Children, 1935, 49, 625—628).—Simultaneous sensitivity to tuberculo-protein (by  $\text{CO}_2\text{H}$  pptn.) differs with age.  
CH. ABS. (p)

Effect of reduced glutathione on the curative action of neosalvarsan in the nagana-infected mouse. C. MONCORPS and R. M. BOHNSTEDT (Arch. Dermatologie, 1934, 170, 26—32; Chem. Zentr., 1934, ii, 3983).—Glutathione (I) increases the virulence of trypanosomes, and detoxifies neosalvarsan. In mice infected with *T. nagana* the action of (I) is weakened by small quantities of (I) (subcutaneous) but strengthened by large quantities (intravenous).  
N

Study of gastric acid secretion by fractional analyses in cases of gastric and duodenal ulcers. DELFINO (Pathologica, 1935, 27, 261—268).—representing changes of titratable acidity with time of extraction of the gastric secretion are parabolic in normal cases but not in cases of ulceration.  
CH. ABS. (p)

regulation of basal metabolism. L. AN (Orvosi Hetilap, 1935, 79, 311—314).—Basal metabolism is not influenced by agents affecting cerebral centres. Narcotics cause a change of 10%.  
CH. ABS. (p)

B in children of normal and a intelligence. Blood-cholesterol and creatinine values. B. ROTHBART (Amer. J. Dis. Children, 1935, 672—688).—No correlation was apparent between metabolic rates and intelligence quotients.  
CH. ABS. (p)

S action of amino-acids. I. E. effect of glucose on the specific-dynamic action of glycine. II. Effect of configuration on specific-dynamic action. III. Dependence of specific-dynamic action on amino-group content. Y. MASAI, T. UCHI, and T. FUKIWAKE (Biochem. Z., 1936, 283, 159—168, 169—173, 174—179).—I.

In fasting rabbits, distilled  $\text{H}_2\text{O}$ , orally administered, has no sp.-dynamic action and during the fast that of glucose (I) is very weak. The sp.-dynamic action of glycine (II) gradually decreases and finally disappears as fasting continues. The action of (II) is weakened and curtailed by administration of phloridzin. In both cases previous administration of (I) increases the action of (II). Hence the presence of (I) is essential for the development of the sp.-dynamic action of (II).

II. The sp.-dynamic action of *l*-alanine, *l*-glutamic acid, and *l*-aspartic acid is respectively > that of the corresponding *d*- and *dl*-acids, the action of *dl*-aspartic acid being very weak.

III. For each  $\text{NH}_2$ -acid there is an optimal amount which has the most powerful sp.-dynamic action, this being less powerful with larger or smaller amounts. There is no relation between the amount of  $\text{NH}_2$ -acid given or its  $\text{NH}_2$  content and the magnitude of the action. The action of urea is strong, but weaker than that of (II) and alanine.  
W. McC.

Diffusion of nitrogenous compounds from frog muscles in Ringer's solution. W. O. FENN (J. Cell. Comp. Physiol., 1935, 6, 469—485).—Frog muscles in Ringer's solution at 22° lose about  $52 \pm 6$  mg. of N per 100 g. of muscle in 5 hr., half the N lost being protein, and the remainder urea, creatine, and  $\text{NH}_2$ -acids. In solutions of varying  $[\text{K}^+]$  the loss in protein  $\propto$  the gain in  $\text{Cl}^-$ , with a min. at about 50 mg. of K per 100 g. Protein loss is increased by rise of temp., asphyxia, and frequent renewal of the solution; non-protein-N loss is increased by stimulation and asphyxia. Both N losses are reduced by previous perfusion of the muscle with Ringer's solution. During immersion in Ringer's solution  $p_{\text{H}}$  falls in the muscles and rises in the solution, owing to loss of  $\text{K}^+$  and gain of  $\text{Cl}^-$  by the muscle. Ringer's solution as a medium for muscle is abnormal.  
R. N. C.

Water balance of a marine mammal, the seal. L. IRVING, K. C. FISHER, and F. C. McINTOSH (J. Cell. Comp. Physiol., 1935, 6, 387—391).  
R. N. C.

Mechanism by which the acidity of an acid meal is reduced in the stomach. F. C. HILL, L. C. HENRICH, and C. M. WILHELMJ (Surg. Gynecol. Obstet., 1935, 60, 966—968).—The mechanism includes neutralisation and the regurgitation of duodenal fluids. The two factors may be determined by use of phenolphthalein. In dogs vals. were 35 and 65%, respectively.  
CH. ABS. (p)

Metabolism of injured tissue. (A) W. FLEISCHMANN. (B) H. DRUCKREY (Naturwiss., 1936, 24, 15; cf. this vol., 102).—The results of Druckrey are in harmony with previous work, e.g., that by Fleischmann on the metabolism of leucocytes.  
W. O. K.

Metabolism of injured tissue. H. DRUCKREY (Arch. exp. Path. Pharm., 1936, 180, 231—250; cf. this vol., 102).  
F. O. H.

Tissue metabolism. VIII. Effect of fumarate and succinate on tumour respiration. E. BOYLAND and M. E. BOYLAND (Biochem. J., 1936, 30, 224—226).—Respiration of tumour tissue, like

that of muscle, kidney, and liver, is increased by succinate or fumarate and decreased by malonate.

H. G. R.

**Exhaustion of the respiratory capacity *in vitro* of some tissues.** G. DOMINI and P. PERUZZI (Boll. Soc. ital. Biol. sperim., 1935, 10, 493—496).

R. N. C.

**Respiration *in vitro* of some tissues in relation to the growth-curve of the organism.** P. PERUZZI (Boll. Soc. ital. Biol. sperim., 1935, 10, 489—493).—O<sub>2</sub> consumption by surviving muscle, spleen, and liver sections of the albino rat rises to a max. during the period when body-wt. has reached 40—60 g., and then falls to a steady val.

R. N. C.

**Utilisation of oxygen by *Mya arenaria*.** L. VAN DAM (J. Exp. Biol., 1935, 12, 86—94).—The O<sub>2</sub> utilisation coeff. is normally 3—10%, but increases temporarily to 25% after a period of anaerobiosis.

CH. ABS. (p)

**Anoxybiosis of the embryo of *Rana fusca* in different stages of development.** I. LATINIR-VETULANI (Bull. Acad. Polonaise, 1935, B, 273—278).—The effect of anaerobic conditions on CO<sub>2</sub> production by the embryo varies with the stage of development. The mechanism of these effects is examined.

A. G. P.

**Respiratory quotients during embryonic development (Orthoptera).** E. J. BOELL (J. Cell. Comp. Physiol., 1935, 6, 369—385).—Bound CO<sub>2</sub> in eggs of *Melanoplus differentialis* increases during development. The O<sub>2</sub> consumption curve reaches a max. in 20 days at 25°. In diapause, respiration is maintained at a min. level, but afterwards it increases steadily. The R.Q. shows that fat is the chief metabolite oxidised during development; it decreases slowly in later stages and is probably converted into chitin.

R. N. C.

**Photodynamically-induced oxygen consumption in muscle and nerve.** A. J. KOSMAN and R. S. LILLIE (J. Cell. Comp. Physiol., 1935, 6, 505—515).—Exposure of eosin-stained muscle and nerve to visible light increases O<sub>2</sub> consumption by 135—183% and 133—144%, respectively. The increase is unaffected by Ca<sup>++</sup>, Na salt solutions, CN<sup>-</sup>, or boiling. Ovalbumin stained with eosin consumes O<sub>2</sub> in presence of light; glucose-eosin solutions, either alone or in presence of adsorbents, do not. Irradiated fat-free muscle extracts but not protein-free extracts consume O<sub>2</sub>. The photodynamic effect in skeletal muscle is possibly associated with the membrane proteins.

R. N. C.

**Energy sources in ontogenesis. VIII. Respiratory quotient of developing gastropod eggs.** E. BALDWIN (J. Exp. Biol., 1935, 12, 27—35).—Throughout development the R.Q. was 1.05. Fat synthesis is indicated. The increase in CO<sub>2</sub> content of the eggs coincides with the formation of true shell. Synthetic fat is probably not derived from protein. Uric acid is synthesised by the embryo during the later period of development.

CH. ABS. (p)

**Nutrition and national health.** (Sir) R. McCARRISON (Roy. Soc. Arts., 1936, 56 pp.).—Cantor Lectures.

**Nutritive value of canavanine.** M. KITAGAWA and M. WADA (J. Agric. Chem. Soc. Japan, 1935, 11, 1083—1088).—Dietary experiments on rats failed to elucidate the growth-promoting action of canavanine (cf. Ogawa, A., 1934, 1391).

F. O. H.

**Nutritive value of mustard oil.** B. B. BRAHMACHARI (Indian Med. Gaz., 1934, 62, 327—329).—The oil contains no vitamin-A and tends to inactivate -A in other foods. It has a nutritive val. similar to that of other fats provided the -A supply is adequate.

CH. ABS. (p)

**Comparison between the nutritive value of some legumes and some cereals.** V. ZAGAMI and V. FAMIANI (Arch. ital. Biol., 88, 119—127; Chem. Zentr., 1935, i, 3301).

G. H. F.

**Nutritive value of alcohol-extracted animal tissues, and supplements required for growth and lactation.** W. H. SEEGER and H. A. MATTIL (Proc. Iowa Acad. Sci., 1934, 41, 173—174).—Extracted tissues (beef heart, kidney, round, and liver) produced inferior growth in rats to that obtained with whole tissues. The deficiency was supplied by the EtOH-extract of liver.

CH. ABS. (p)

**Determination of digestibility coefficients. I. Method and computation for directly obtaining coefficients of individual nutrients in a mixed ration.** M. CARBERY, I. CHATTERJEE, and M. A. HYE (Indian J. Vet. Sci., 1934, 4, 295—340).—Methods utilising graphical and multiple regression equations are described.

CH. ABS. (p)

**Nutritional investigation of the porgy. IV. Fractionation of porgy meat.** Y. HATAKOSHI (J. Chem. Soc. Japan, 1935, 56, 221—229).—Max. dissolution of protein from ground meat was obtained with 0.1N-NaCl or 0.02N-NaOH.

CH. ABS. (p)

**"Disequilibrating" effect of fructose.** R. LECOQ (Compt. rend. Soc. Biol., 1936, 121, 226—228).—Fructose (I) causes disequilibrium when present in the diet to 80—84% of the total carbohydrates. The disequilibrium is not so accentuated as with galactose or lactose. Equilibrium is established with 35% of (I), and with 66% if yeast is added to the diet.

R. N. C.

**Metabolism of the lung-fish. II. Effect of feeding meat on metabolic rate.** H. W. SMITH (J. Cell. Comp. Physiol., 1935, 6, 335—349).—Lung-fish fed with meat exhibit a rise of O<sub>2</sub> consumption, and fasting causes a logarithmic decrease.

N C

**Organic matter in dissolved and colloidal form as food for *Daphnia magna*.** S. S. GELLIS and G. L. CLARKE (Physiol. Zool., 1935, 8, 127—137).—The animals require colloidal nutrients.

CH. ABS. (p)

**Nutrition: vegetable proteins.** L. B. MENDEL and H. B. VICKERY (Carnegie Inst. Wash. Yearbook, 1934, 33, 289—295).—In synthetic rations for rats in P-metabolism trials casein may be replaced lactalbumin or, less satisfactorily, partly purified ovalbumin. Highly purified vitamin-B<sub>2</sub> preps. are obtained from liver, protein-free milk, or yeast extraction with 5% HCl, adsorption on activated fuller's earth, and elution with NH<sub>3</sub> or C<sub>5</sub>H<sub>5</sub>.

Yellow solutions showing green fluorescence (especially in ultra-violet light) are produced. A yeast constituent other than  $-B_1$  or  $-B_2$  is required for satisfactory growth of rats. The cystine content of haemoglobin (Cu<sup>1</sup> mercaptide method) is: horse 0.41, sheep 0.61, dog 1.16%. Histidine was completely pptd. from protein hydrolysates by  $HgCl_2$ . In addition to nicotine, green tobacco leaves contain *N*-methylpyrrolidine and nornicotine, but no sol. quaternary bases other than volatile alkaloids.

CH. ABS. (p)

**Influence of protein on longevity.** C. Y. CHEN (Nat. Peiping Univ. Coll. Agric. Nutrition Bull., 1935, B, 2, 12—21).—On a 9% protein level the life span of rats was shortest on a beef diet and the longest on a mixed cereal diet containing maize protein 2, casein or soya-bean protein 1.

CH. ABS. (p)

**Protein metabolism and oxidation processes in experimental scurvy. III. Urea and creatinine excretions in experimental scurvy and the effect of iron.** L. D. KASHEVNIK and I. B. FRIDLAND (Biochem. Z., 1935, 282, 265—268).—The urinary creatinine in guinea-pigs increases during the development of scurvy and also by addition of Fe to the diets. Addition of Fe, however, does not affect urea excretion.

P. W. C.

**Histochemical studies of the development of fish. I. Vitellogenesis in the gudgeon (*Gobio fluviatilis*) and the carp (*Cyprinus carpio*).** B. KOSOPACKA (Bull. Acad. Polonaise, 1935, B, 163—). Appropriate histological technique is described and the stages of formation of vitellin during the growth of the oocyte are examined.

A. G. P.

**Synthesis of creatinephosphoric acid in organ extracts and in living spermatozoa.** I. TORRES (Z., 1935, 283, 128—133).—The transfer of  $PO_4^{'''}$  from phosphopyruvic acid (I) to creatine occurs in many organ extracts, most rapidly in muscle and next in extract of testicles, the activity in the latter case being related to the sperm content. In living sperms on addition of (I) and creatine show a considerable synthesis of creatinephosphoric acid.

P. W. C.

**Utilisation of tryptophan administered subcutaneously.** V. DU VIGNEAUD, R. R. SEALOCK, VAN ETTEN (J. Biol. Chem., 1936, 112, 451—).—view Alcock's contention (A., 1934, 1392) that tryptophan (I) produces no growth response in (I)-deficient animals, earlier work indicating the contrary (1933, 89) was repeated and confirmed. The discrepancies remained when Alcock's technique was used exactly.

H. D.

**Availability of tryptophan derivatives for supplementing diets deficient in tryptophan.** C. P. BLERG and H. E. HANSON (Proc. Iowa Acad. Sci., 1934, 31, 102—).—cf. A., 1935, 1405).—Utilisation of tryptophan by rats is prevented by benzoylation but not by acetylation or esterification (EtOH). The *p*-propyl and phenylpropionyl derivatives of (I) as well as *p*-Ph and  $CH_2Ph$  ester hydrochlorides (but not the phenylacetate) were utilisable.

CH. ABS. (p)

**Production of a deficiency involving cystine and homocysteine by the administration of cholic**

acid. A. WHITE (J. Biol. Chem., 1936, 112, 503—509).—Rats fed on a diet low in cystine (I) and containing cholic acid (II) lost wt., but addition of either *L*-(I) or *DL*-methionine (III) caused resumption of growth. Taurine and  $Na_2SO_4$  were ineffective. The deficiency in (I) and (III) produced by (II) may be due to the demand for taurine for the synthesis of taurocholic acid, or to a direct detoxication of (II) by (I) and (III).

J. N. A.

**Influence of feeding amino-acids and other compounds on the excretion of creatine and creatinine.** M. BODANSKY (J. Biol. Chem., 1936, 112, 615—624).—Comparatively large doses of arginine, aspartic acid, glutamic acid, cystine, histidine, tyrosine, choline, betaine, sarcosine, and salts of guanidine had no effect on the excretion of creatine (I) and creatinine in rats. Glycine, guanidinoacetic acid, and to a smaller extent, alanine increased the output of (I). 30—80% of (I) given in doses of 35—120 mg. was recovered in the urine within 48 hr.

J. N. A.

**Resorption of bile acids in the small intestine.** E. FROLICHER (Biochem. Z., 1936, 283, 273—279).—In the small intestine of rats taurocholic acid is more readily absorbed than are cholic and glycocholic acid. The absorption of the acids is more rapid in the lower than in the upper part of the intestine. The differences are not due to variations in  $p_H$  (5.9, 7.8) or to excretion of bile acids by the upper part of the intestinal mucous membrane.

W. McC.

**Indican. IV. Absorption of indoles and indican synthesis in the body. V. Excretion of indican by bile.** H. INOUE (J. Chosen Med. Assoc., 1934, 24, 1519—1536; 25, 121—135).—IV. In rabbits and dogs absorption of indoles can be greater in the small than in the large intestine. Some absorbed indole passes into blood by the lymphatics. Synthesis of indican (I) occurs in liver and lungs but not in kidneys or intestines. Emulsions from liver and lungs synthesise (I) *in vitro* (optimum  $p_H$  6.8—9.0).

V. Normal bile contains 0.06—0.12 mg. of (I) per 100 c.c., vals. being close to those in blood at the time of excretion.

CH. ABS. (p)

**Formation of xanthurenic acid: experiments on man.** F. M. CHIANCONE (Boll. Soc. ital. Biol. sperim., 1935, 10, 578—580).—Administration of kynurenine (I) to a healthy man produces the diazo-reaction in the urine, but none of the other reactions of xanthurenic acid. (I) is present in the urine, and is probably responsible for the diazo-reaction.

R. N. C.

**Phosphatide metabolism and the influence of thyroïdin.** L. PASTERNAK and I. H. PAGE (Biochem. Z., 1935, 282, 282—292).—Phosphatide (I) injected intraperitoneally into white mice is not stored, but is completely utilised. The muscle-(I) in rats after treatment with thyroïdin (II) increases by 96%. This increase is not due to any injury of the (I)-degrading power nor to any infiltration of (I) from other tissues. It is not a relative, but an abs. increase due probably to a synthesis of (I) under the action of (II), possibly as intermediate products in the degradation of fat.

P. W. C.

**Choline and dietary production of fatty livers.** C. H. BEST, H. J. CHANNON, and J. H. RIDOUT (J. Physiol., 1934, 81, 409—421).—Fatty liver caused by high-fat diet is due to an increase in the neutral fat fraction. That caused by cholesterol is due to excessive amounts of cholesteryl esters with an increase in neutral fat. The phosphatide (I) content of both types of fatty liver is inversely  $\propto$  the total lipin content. Choline prevents the occurrence of both types of fatty liver, and increases the % of (I) in the livers without disproportionate increases in lecithin and sphingomyelin. CH. ABS. (p)

**Physiology of lipins and sterols under complete and protein inanition.** S. VALLA (Bull. Soc. Chim. biol., 1935, 17, 1715—1740).—A comparison is made of the lipin and sterol content of normal mice and animals undergoing complete and protein starvation. Although the length of life under protein starvation is  $>$  that under complete starvation, the continuous carbohydrate intake in the first case does not prevent the complete utilisation of the fatty reserves. Fasting increases both cholesterol and total N of the animals. A. L.

**Fat metabolism. I. Effect of ingestion of olive oil on lipin contents of rabbit tissues. II. Effect on lipin contents of splenectomised rabbit tissues. III. Effect on sulphur distribution in rabbit tissues.** Y. SONEDA (Sci-i-Kwai Med. J., 1934, 53, No. 8, 49—65, 66—87, 88—91).—I. Daily administration of 10 c.c. of olive oil increased the fat acid (I) and lecithin (II) contents of spleen and adrenals, and the cholesterol (III) in spleen and (slightly) in kidneys. Other organs were unaffected.

II. Splenectomy lowered the (I), (II), and (III) in all organs. Administration of olive oil markedly increased the (I) of the lungs, decreased the (III) : (I) and (III) : (II) ratios of the kidneys, and increased the (II) : (I) ratio in the heart.

III. Feeding of olive oil caused a considerable increase in liver-S, and a slight increase in S of all other organs except lungs (decrease) and kidneys (no change). CH. ABS. (p)

**Combustion of odd-numbered fatty acids in the animal organism.** S. SKRAUP and E. STRIECK (Verh. Ges. Verdauungs- u. Stoffwechselkrankh., 1934, 132—136; Chem. Zentr., 1934, ii, 3784).—Saturated  $C_{11}$  and  $C_{13}$  fatty acids are not oxidised in the body of the dog when administered alone, but the oxidation is catalysed by small quantities of unsaturated fats which are not themselves oxidised. R. N. C.

**Central regulation of fat metabolism in the epidermis.** A. PERUTZ, B. LUSTIG, and A. E. KLEIN (Arch. Dermatol. Syphilis, 1934, 170, 511—520; Chem. Zentr., 1934, ii, 3784).—Destruction of the mid-brain followed by prolonged feeding with fatty substances in rabbits increases hair-fat and blood- $\beta$ -hydroxybutyric acid, blood-ketones being unaffected. Fat excretion by the skin is therefore probably regulated by a central mechanism. R. N. C.

**Fat metabolism in the course of gestation of *Trygon violacea*.** G. STOLFI (Boll. Soc. ital. Biol. sperim., 1934, 9, 1315—1316).—The I vals. of the

fats of the uterine liquid and embryonal tissues are  $<$  that of the maternal liver, which hence must undergo a saturation process in order to be utilised by the foetus. R. N. C.

**Nutritive effect of plant gums on formation of fat and glycogen.** H. IWATA (Bul. Sci. Fak. Terkult. Kjusu, 1933, 5, 352—366).—Feeding gum arabic or starch to rabbits did not increase glycogen formation. Blood-protein-N and haemoglobin were unchanged but -total sugar increased somewhat. CH. ABS. (p)

**Influence of acid-base equilibrium on the glycogen content of the liver.** S. KUMAMURA (Trans. Soc. Path. Japan, 1934, 24, 2—5).—Acidosis decreases, and alkalosis increases, liver-glycogen. CH. ABS. (p)

**Glycogenic function of the liver in the chicken embryo.** A. GUELIN-SCHERINA (Compt. rend. Soc. Biol., 1936, 121, 144—146).—Insulin does not cause the premature appearance of liver-glycogen (I) in the developing chick embryo; (I) appears at a later stage than the pancreas. R. N. C.

**Glycogen metabolism of the organiser in amphibian gastrula.** C. P. RAVEN (Proc. K. Akad. Wetensch. Amsterdam, 1935, 38, 1107—1109).—When pieces of ectoderm were inserted in the dorsal lips of the blastospore of the embryo, there was a definite decrease of glycogen (I) in those cells which had involuted. This loss of (I) is closely connected with the involution. J. N. A.

**Initial transformations of glycogenolysis: function of hexose monophosphoric ester.** P. OSTERN and J. A. GUTHKE (Compt. rend. Soc. Biol., 1936, 121, 232—235).—Glycogen is first broken down to hexose monophosphate, which then reacts with adenosinetriphosphoric acid to form hexose diphosphate. R. N. C.

**Utilisation of *d*-mannoheptulose (*d*-manno-ketoheptose) by adult rabbits.** J. H. ROE and C. S. HUDSON (J. Biol. Chem., 1936, 112, 443—449).—Rabbits fed with *d*-mannoketoheptose (I) showed an increased blood-sugar which was not accounted for by the blood-(I); (I) is converted into a reducing substance fermentable by yeast. The conversion does not occur in the liver, but during the process of intestinal absorption. Insulin accelerates the oxidation of the reducing substance formed from (I). H. D.

**Hydrolysis, oxidation, and energy changes in dogs. IV. Absorption of fructose by the organs of dogs *in vivo*.** M. WIERZUCHOWSKI and H. FISZEL (Biochem. Z., 1935, 283, 30—44).—Further work on the utilisation of fructose (I) is described (cf. A., 1935, 1017, 1542). The absorption velocities of (I) by the organs of the dog are, in mg. per g. per hr., for liver 21, organs of the portal system 3.5, motor system 0.4, muscle only 0.8, organs of the head 0.39, other organs 2.0. Simultaneously glucose is being formed by the liver and is being absorbed by the organs of the head with a velocity of 1.3, of the portal system 1.0, motor system 0.02, other organs 0.32. One fifth of the (I) absorbed is returned by the liver to the blood as lactic acid. The organs of

the head and portal system do not appear to give lactic acid in this way. The glucose-forming power of the liver is unchanged during the introduction of inositol, Na lactate, and MeCHO. P. W. C.

#### Chief method of lactic acid formation in muscle.

O. MEYERHOF and W. KRIESSLING (Biochem. 1935, 283, 83—113).—Lactic acid (I) arises in muscle chiefly by the oxidation of 1 mol. of triosephosphoric acid to phosphoglyceric acid with simultaneous reduction of 1 mol. of  $\text{AcCO}_2\text{H}$  to (I). This reaction proceeds much more rapidly than does the earlier described reaction in which  $\alpha$ -glycerophosphoric acid +  $\text{AcCO}_2\text{H}$  gave 2 mols. of (I). The stages of the new reaction can be separated using NaF and  $\text{CH}_2\text{I}\cdot\text{CO}_2\text{H}$  in the same way as with alcoholic fermentation. A complete scheme of the intermediate reactions in muscle is given, and it is seen that in muscle  $\text{AcCO}_2\text{H}$  is the biological equiv. of MeCHO and (I) of EtOH of alcoholic fermentation.  $\text{PO}_4^{4-}$  changes involve the muscle-adenylic acid system. The scheme is in close agreement with the requirements of the Harden-Young equation. P. W. C.

Effect of hydrazine on the production of ketonic substances in the phloridzin-intoxicated animal. M. M. GREENBERG (J. Biol. Chem., 1936, 112, 431—436).—Phloridzinised rats, treated with  $\text{N}_2\text{H}_4$ , showed a decreased excretion of ketones which was not due to kidney retention, decreased deamination of  $\text{NH}_2$ -acids, or increased glucose or protein metabolism. H. D.

Comparison of the tendencies of different animal species to ketonuria and ammoniuria. E. F. TERROINE and H. TRIMBACH (Arch. int. Physiol., 1934, 39, 377—416; Chem. Zentr., 1934, ii, 3980).—Ketonuria in milk-fed animals is higher in those of smaller body-wt., but is independent of the amount of food ingested per kg. The ratio  $(\text{COMe}_2 + \text{CH}_3\text{Ac}\cdot\text{CO}_2\text{H})/\beta$ -hydroxybutyric acid in the excreta is generally 30 : 70, but is less for the cat and hedgehog.  $\text{NH}_3$  excretion differs greatly with the species, and is independent of the type or quantity of the food. R. N. C.

Acetaldehyde in muscular work and avitaminosis-B. H. HANDOVSKY (Compt. rend. Soc. Biol., 1935, 120, 1357—1358).—Blood-MeCHO is not modified in the dog by muscular work. Injection of MeCHO in vitamin-B-deficient pigeons delays death. R. N. C.

Fate of alcohol in the corpse of an alcoholised mammal : formation of alcohol in non-alcoholised control animals. M. NICLOUX (Compt. rend. Biol., 1935, 120, 1306—1309).—The rate of disappearance of EtOH from the corpse of an alcoholised mouse increases with temp. Formation of EtOH occurs in non-alcoholised control animals; the rate of formation increases with temp., but it always rises to a max. and then falls. The highest max. occurs at 15—18°. R. N. C.

Mineral metabolism of pullets. II. R. H. SIMON (J. Agric. Sci., 1936, 26, 85—100; cf. A., 1933, 1326).—Heavy P excretion during egg laying increased excretion of  $\text{NH}_3\text{-N}$ . Probably the excess of P is eliminated as  $\text{NH}_4$

phosphate in the urine. Excreted P is not unduly high if the intake of  $\text{CaCO}_3$  is adequate. Pullets receiving 5% of  $\text{CaCO}_3$  in the ration produced eggs with a higher P content than when the  $\text{CaCO}_3$  was omitted. A. G. P.

Renal threshold of potassium. H. GRIFFON (Compt. rend. Soc. Biol., 1936, 121, 47—49).—Theoretical. R. N. C.

Aluminium in nutrition. H. H. KEIL and V. E. NELSON (Proc. Iowa Acad. Sci., 1934, 41, 161—164).—Of the salts examined the order of toxicity was  $\text{Al}(\text{OH})(\text{OAc})_2 < \text{K alum}$  and  $\text{Al}(\text{NO}_3)_3 < \text{AlCl}_3$ . CH. ABS. (p)

Influence of lungs on salt metabolism. S. RYU (J. Chosen Med. Assoc., 1934, 24, 1404—1410).—Blood-Cl in the right heart of the rabbit is  $>$ , and the plasma-Cl  $<$ , the corresponding amounts in the left. Passage of  $\text{CO}_2$  into arterial blood increases plasma-Cl and decreases corpuscular Cl. Reverse effects occur in venous blood. Lungs not only remove Cl from blood but regulate Cl distribution by the gaseous exchange. CH. ABS. (p)

Probable nervous mechanism of the increase of the reducing power of the aqueous humour under the action of light. A. BONSIGNORE (Boll. Soc. ital. Biol. sperim., 1935, 10, 505—509).—The increased ascorbic acid content is probably due to parasympathetic action. R. N. C.

Insolation and acidosis. G. DI MACCO (Boll. Soc. Ital. Biol. sperim., 1935, 10, 437—438).—Administration of HCl to rabbits delays death from insolation. R. N. C.

Increase of cell permeability by mitogenetic irradiation. (Chemical detection of the mitogenetic effect.) I. R. BACHROMEJEV (Biochem. Z., 1935, 282, 297—302).—The small amounts of inorg. P, phosphatide, phosphatase, sugar, and catalase separated from surviving mouse liver into Ringer's solution are very largely increased when the liver is previously subjected to mitogenetic irradiation for  $\frac{1}{2}$  hr. P. W. C.

Role of the reticulo-endothelial system in the fixation of radiothorium. K. SCHACHOWITZ, D. K. JOWANOWITSCH, and M. WISCHNITSCHewa (Glas Srpske kraljevske Akad., 1933, 78, 65—73; Chem. Zentr., 1934, ii, 3401). R. N. C.

Radioactive effect of potassium on the vegetative nervous system. O. MERCK (Strahlenther., 1934, 50, 471—475; Chem. Zentr., 1934, ii, 3786). R. C. N.

Influence of changes in the medium on the development of eggs of *Bothriocephalus scorpii* (Müller 1776). S. MARKOWSKI (Bull. Acad. Polonaise, 1935, B, 49—58).—Eggs are not susceptible to any but extreme changes in salt concn. in the medium. Light intensity is a more important factor. A. G. P.

Behaviour of the water-flea, *Daphnia pulex*, de Geer, in media of different hydrogen-ion concentrations. K. PASSOWICZ (Bull. Acad. Polonaise, 1935, B, 59—86).—Optimum development occurs at  $p_H$  7.3. With  $p_H$  5.7 and 6.0 the population

of *D. pulex* in a culture is restricted but the parthenogenetic increase of the survivors is not affected.

A. G. P.

**Embryonic and larval development in *Saccolina (Rhizocephala)* in media of changed osmotic condition.** M. RAMULT (Bull. Acad. Polonaise, 1935, B, 87—109).—Effects of hypo- and hypertonic solutions on the various stages of development are examined.

A. G. P.

**Water exchange and fatigue: effect of ingestion of water on tachycardia and hyperpnoea from work.** G. DI MACCO (Boll. Soc. ital. Biol. sperim., 1935, 10, 436—437).

R. N. C.

**Electromotive force in biological systems.**

IV. **Effect of carbon monoxide on the electromotive force of frog skin.** A. B. TAYLOR and E. J. BOELL (Proc. Iowa Acad. Sci., 1934, 41, 316—317; cf. A., 1934, 327).—The e.m.f. of frog skin is depressed by CO in CO-O<sub>2</sub> mixtures. The effect is not due to decreased [O<sub>2</sub>]. No additional change occurs in darkness. Aeration causes a return to normal (and sometimes > normal) vals.

CH. ABS. (p)

**Sensitisation of animals with simple chemical compounds.** K. LANDSTEINER and J. JACOBS (Proc. Soc. Exp. Biol. Med., 1934, 31, 790, 1079).—Positive effects on guinea-pigs are obtained with a no. of substances. The mechanism of the action is discussed.

CH. ABS. (p)

**Harmful effect of certain chemicals on the uterus of the rat.** F. E. D'AMOUR and N. KIVEN (Amer. J. Obstet. Gynecol., 1935, 29, 503—509).

CH. ABS. (p)

**Toxic action of heavy metal salts on the three-spined stickleback (*Gasterosteus aculeatus*).** J. R. E. JONES (J. Exp. Biol., 1935, 12, 165—173).—Toxic effects of the salts are largely due to the cations, although anions have some influence, e.g., SO<sub>4</sub><sup>2-</sup> > NO<sub>3</sub><sup>-</sup> or Cl<sup>-</sup>. Difference in toxicity is closely related to difference in electrical conductivity.

CH. ABS. (p)

**Mammalian organism and action of metallic salts.** L. E. WALBUM (Z. Immunitats., 1934, 82, 399—419).

R. N. C.

**Influence of neutral salts on the photodynamic stimulation of muscle.** R. S. LITTLE, M. A. HINRICHS, and A. J. KOSMAN (J. Cell. Comp. Physiol., 1935, 6, 487—501).—Pure Na salts in solution sensitise eosin-stained muscles to stimulation by light, the efficiencies of the anions being Cl<sup>-</sup> < Br<sup>-</sup> < NO<sub>3</sub><sup>-</sup> < I<sup>-</sup>. Stained muscles irradiated in Ringer's solution are sensitised to subsequent stimulation by Na salts: staining alone has a depressant action. Ca<sup>2+</sup> inhibits the photodynamic response, which is more sensitive to Ca<sup>2+</sup> than to Na<sup>+</sup>. O<sub>2</sub> is essential to photodynamic response.

R. N. C.

**Effect of iodine on the sexual organs and growth in the rat.** A. LIPSCHUTZ and E. MORALES (Compt. rend. Soc. Biol., 1936, 121, 337—340).

R. N. C.

**Iodine compounds and fertilisation. IX. Fertilisation in the starfish, *Asterias rubens*.** L. G. S. CARTER (J. Exp. Biol., 1935, 12, 108—118; cf. A., 1932, 1285).—Immature starfish sperm is activated and the fertilisability of unripe eggs is

improved by treatment with thyroxine (I). Ripe sperm and eggs are unaffected. (I) causes a temporary rise in the O<sub>2</sub> consumption of unripe eggs.

CH. ABS. (p)

**Interpretation of the [physiological] action of some preparations of bromine.** I. SIMON (Boll. Soc. ital. Biol. sperim., 1935, 10, 382—383).—Injection of dibromocholesterol in olive oil in rabbits causes a deposition of Br in the blood, liver, kidney, and adipose tissue, but not in the brain.

R. N. C.

**Effect of cupric, manganous, and ferric chlorides on cardiac explants in tissue culture.** D. C. HETHERINGTON and M. E. SHIPP (Biol. Bull., 1935, 68, 215—230).—Low concns. of the salts produced stimulatory and higher concns. toxic effects. A combination of the three chlorides was very toxic.

CH. ABS. (p)

**The combination of iron and copper and their relation to blood-formation and to general metabolism, and the connexion between their effects and the crystalline state of the metals.** S. ODA (Z. ges. exp. Med., 1932, 84, 719—727; Chem. Zentr., 1935, i, 3154).—Active Fe<sub>2</sub>O<sub>3</sub> (Siderac) (I) causes no polycythæmia in normal animals, but produces changes in the urinary C/N ratio. Cu-albumin compounds or Cu glycerophosphate cause polycythæmia, are efficacious in experimental anæmia, and affect the urinary ratio. Mixtures of (I) and Cu compounds have the greatest effect on blood and C/N ratio, but cryst. combinations of Cu and (I) have no effect on blood formation.

G. H. F.

**Therapeutic action of iron.** L. J. WITTS (Lancet, 1936, 230, 1—5).—Factors affecting the requirement, absorption, and utilisation of Fe are discussed. Absorption of Fe from food or drugs ∝ the ease with which Fe<sup>2+</sup> ions are liberated. Fe is a nutrient and not a stimulant for blood-forming organs.

L. S. T.

**Mercurial (novurit) suppository as a diuretic for cardiac oedema.** J. PARKINSON and W. A. R. THOMSON (Lancet, 1936, 230, 16—19).

L. S. T.

**Action of potassium on formation of lactic acid and breakdown of phosphagen in the isolated muscle of the frog.** D. NACHMANSOHN, J. WAJZER, and A. MARNAY (Compt. rend. Soc. Biol., 1936, 121, 141—142).—Excess of K<sup>+</sup> accelerates lactic acid formation and phosphagen breakdown in the isolated muscle in anaerobiosis.

R. N. C.

**Physiological and pharmacological action of sulphur.** F. M. CHIANCONE (Boll. Soc. ital. Biol. sperim., 1933, 8, 1511—1513).—S injected subcutaneously in dogs in aq. EtOH-glycerol solution increases the resistance of the erythrocytes, and also augments the alkaline reserve of the plasma, thus favouring the O<sub>2</sub>-fixing power of hæmoglobin and increasing the buffering power of the blood. The intracellular oxidation-reduction processes are maintained and accelerated.

R. N. C.

**Action of Viterbo sulphurous water on germination and on the activity of the epithelium of frog's oesophagus.** A. ROSSINI (Annali Chim. Appl., 1935, 25, 541—557).—The SO<sub>2</sub>-containing H<sub>2</sub>O (ana-

lyses given), after a brief initial retardation, accelerates the germination and growth of wheat and lentil when compared with controls in normal  $H_2O$  or Knop's solution. The movements of ciliated epithelial cells are depressed and finally (1—2 hr.) arrested. F. O. H.

Action of some natural mineral waters on the isolated heart. G. GUIDI (Boll. Soc. ital. Biol. sperim., 1935, 10, 432—434). R. N. C.

Action of hydrocyanic acid on carbon dioxide assimilation and respiration of *Stichiococcus bacillaris*. F. VAN DER PAAUW (Planta, 1934, 24, 353—360).—Small amounts of HCN accelerate assimilation and respiration under conditions of high or low light intensity. The inhibitory effect of larger dosages of HCN is more marked in high light intensity. A. G. P.

Fixation of propyl bromide in the blood and brain of the guinea-pig, after preliminary administration of different poisons of the central nervous system. M. TIFFENEAU and D. BROWN (Compt. rend. Soc. Biol., 1935, 120, 1169—1170).—The  $Pr^{Br}$ -fixing capacity of the brain is reduced by hypnotics (chloralose, soneryl, urethane), but increased by stimulants such as caffeine. R. N. C.

Pharmacology of bromoacetic acid. H. FREUND (Arch. exp. Path. Pharm., 1936, 180, 199—208).—The mechanism of the sp. actions of  $CH_2BrCO_2H$  on carbohydrate metabolism of animals and bacteria and of the toxic action on ascarides (the muscular contraction of which is compared with that due to santonin) is discussed. F. O. H.

Elimination of sodium formaldehydesulphoxylate by the kidneys. E. HUG (Compt. rend. Soc. Biol., 1936, 121, 365—367).—The kidneys of the dog have a concentrating capacity of 2—2.5% for the compound. The greater part is excreted in 2—3 hr. after injection. R. N. C.

Pharmacology of tetraethylammonium phosphate. I. SIMON (Arch. int. Pharmacodyn. Thé., 1934, 47, 75—95; Chem. Zentr., 1934, ii, 3981). R. N. C.

$\beta$ -n-Alkylcholine chlorides and their acetyl esters.—See this vol., 319.

Influence of the water vapour content of an odorous gas on the olfactory sense. H. WOERDEMAN (Arch. Neerland. Physiol., 1935, 20, 591—595).—Intensity of the odour of isoamyl acetate when mixed with damp air is > when mixed with dry air. J. N. A.

Relations between simple odorous and odorous irritant stimuli and thiocyanate concentration in the nasal mucus. P. NICCOLINI (Boll. Soc. ital. Biol. sperim., 1935, 10, 429—431).—The [CNS] of the mucus is increased by non-irritant and decreased by irritant odours. R. N. C.

Organic effects of hydrazine derivatives. W. C. HUEPER (J. Ind. Hyg., 1936, 18, 17—36).—The four derivatives examined produced lesions of the same type and in the same site, differing only in degree.  $\alpha$ -Ethyl- $\beta$ -propylacetaldehydehydrazone was the most toxic. Destruction of erythrocytes and leucocytes occurred in all cases. P. G. M.

Relation between the chemical constitution and pharmacological action of phenylhydrazine derivatives. W. F. VON OETTINGEN and W. DEICHMANN-GRUEBLER (J. Ind. Hyg., 1936, 18, 1—16).—Attempts to preserve the antipyretic action of  $NHPh \cdot NH_2$  while decreasing its toxicity have been unsuccessful. Substitution of one or more H by alkyl, aryl, alkoxy, or acyl decreases toxicity, which depends largely on the solubility in  $H_2O$  and the ease of hydrolysis. Introduction of  $Bu$ ,  $CH_2Ph$ , or  $CHO$  yields compounds which have no effect on blood pressure, respiration, etc. because of their stability at high temp. P. G. M.

Action of indole on the dehydrogenating power of tissues. G. F. DE GAETANI (Boll. Soc. ital. Biol. sperim., 1934, 9, 1291—1294).—The dehydrogenating processes are generally diminished; blood-sugar is raised. R. N. C.

Action of diketopiperazines on fibroblasts cultivated *in vitro*. R. TRUHAUT and D. ODIETTE (Compt. rend. Soc. Biol., 1935, 120, 1198—1201).—Growth is stimulated by 2:5-diketopiperazine, and to a smaller extent by glycine. R. N. C.

Alkylglyoxalidines.—See this vol., 344.

Mercury salts of alkylfluoresceins.—See this vol., 352.

Action of  $\beta$ -dinitrophenol (1:2:6) on respiratory exchange and temperature of homeothermic animals. G. SARZANA and D. ELIA (Boll. Soc. ital. Biol. sperim., 1935, 10, 545—546).—2:6-Dinitrophenol increases  $O_2$  consumption in pigeons and rats by about 100%. R. N. C.

Pharmacology of the vegetative nervous system. IV. Point of attack of 2:4-dinitrophenol. B. DE BIASIO (Boll. Soc. ital. Biol. sperim., 1935, 10, 383—385). R. N. C.

Action of phenylglyoxal on the vasomotor innervation of the kidney. E. MARTINI and G. FRANCHI (Boll. Soc. ital. Biol. sperim., 1935, 10, 473—474). R. N. C.

Vagal central action of phenylglyoxal. E. MARTINI (Boll. Soc. ital. Biol. sperim., 1933, 8, 1709—1710).— $BzCHO$  acts similarly to  $AcCHO$ , but is effective in smaller concns. R. N. C.

Urinary sulphate determinations as a measure of benzene exposure. W. P. YANT, H. H. SCHRENK, R. R. SAYERS, A. A. HORVATH, and W. H. REINHART (J. Ind. Hyg., 1936, 18, 69—88).—A marked decrease in the % of inorg.  $SO_4^{--}$  in the urine occurs many weeks before symptoms of anaemia etc. P. G. M.

Proliferation-stimulating action of 1:2:5:6-dibenzanthracene on *Obelia geniculata*. S. P. REIMANN and F. S. HAMMETT (Amer. J. Cancer, 1935, 20, 343—349).—Hydranth development was stimulated in sea- $H_2O$  cultures containing this compound. CH. ABS. (p)

Hypoglycaemic action of methylene-blue. G. PIOTROWSKI (Compt. rend. Soc. Biol., 1935, 120, 1215—1216).—Methylene-blue does not reduce normal blood-sugar in rabbits, but apparently reduces hyperglycaemia caused by adrenaline or glucose. R. N. C.

**Secretion in tissue cultures. I. Inhibition of phenol-red accumulation in the chick kidney.** R. CHAMBERS, L. V. BECK, and M. BELKIN. **II. Effect of sodium iodoacetate on the chick kidney.** L. V. BECK and R. CHAMBERS (*J. Cell. Comp. Physiol.*, 1935, **6**, 425—439, 441—455). R. N. C.

**Influence of pyocyanine on respiration of sea-urchin's eggs.** J. RUNNSTROM (*Biol. Bull.*, 1935, **68**, 327—334).—Pyocyanine (I) increases the respiration of the eggs, the effect being further increased by HCN in unfertilised, but decreased in fertilised, eggs. The block in division of the egg caused by HCN is not removed by (I). The rate of respiration in presence of (I) is  $>$  that in the presence of methylene-blue. Neither the Fe-containing enzyme nor the dehydrase-substrate system acts as a limiting factor for the oxidation rate in the unfertilised or newly fertilised egg. CH. ABS. (p)

**Action of acetylcholine on energy exchange.** V. BASUNTI (*Minerva med.*, 1935, **i**, 486—489).—Subcutaneous injection of acetylcholine (0.2 c.c.) during fasting produces a slight but inconst. increase in respiratory exchange and a definite const. increase in the sp. dynamic effect of foods. CH. ABS. (p)

**Acetyl- $\beta$ -methylcholine (mecholine). Action on blood pressure, skin temperature, and the heart as exhibited by electrocardiograms of hypertensive patients.** I. H. PAGE (*Amer. J. Med. Sci.*, 1935, **189**, 55—64). CH. ABS. (p)

**Developmental growth and the amino-acids. II. *l*-Tryptophan.** F. S. HAMMETT and M. L. ELLIOTT. **III. *d*-Arginine.** F. S. HAMMETT and N. CHATALBASH (*Protoplasma*, 1935, **23**, 457—465, 492—502).—II. Effects of various concns. of *l*-tryptophan (I) on the development of *Obelia* are recorded. The chief function of (I) is that of retarding catabolic activity, hence its indispensability for wt. maintenance. In developmental growth (I) is a sp. determining participant in processes concerned in differentiation or organisation and in the prep. of the tissue reaction basis for new growth initiation.

**III. The function of arginine (II) in growth** is not the regulation of any particular metabolic activity, but participation in preparatory processes essential for organisation of the tissue reaction basis for new growth initiation. The possible significance of (II) in malignancy is discussed. A. G. P.

**Highly active pressor substance from cerebral ventricular fluid of human beings.** I. H. PAGE (*Science*, 1935, **82**, 550).—Intravenous injection into cats of extract of human cerebral ventricular fluid from malignant hypertension cases produces a sharp rise in arterial pressure. Similar extracts prepared from plasma produce a slower but more prolonged rise. L. S. T.

**Vasoconstrictive substance in blood.** M. ENOMOTO (*J. Chosen Med. Assoc.*, 1935, **25**, 14—25).—The amount of vasoconstrictive substances is increased in pulmonary tuberculosis, typhoid, nephritic and hepatic cases. The substance is not destroyed by  $O_2$ ,  $H_2$ , or  $CO_2$ , nor by heating at  $60^\circ$  for 30 min. It is destroyed at  $100^\circ$ . CH. ABS. (p)

**Effect of specific substances of the body on blood pressure in man. III. Action of lacarnol, myoston, padutin, "fourth substance" (Lange), and eutonone on intravenous application.** H. J. WOLF and H. A. HEINSEN (*Z. klin. Med.*, 1934, **127**, 1—14; *Chem. Zentr.*, 1934, **ii**, 3787). R. N. C.

(A) Antagonistic action of lipins to the toxic action of bile salt. (B) Effect of thyroid gland preparation on formation of gastric ulcer by bile salts, and antagonistic action of cholesteryl oleate. (C) Relationship between toxicity of bile salts and their antagonist. K. ISHII (*Sei-i-Kwai Med. J.*, 1934, **53**, No. 9, 94—191, 192—198, 199—211).—(A) Susceptibility to bile salt (I) toxicity in the male is  $>$  in the female starfish. The effect is antagonised by cholesteryl oleate (II) or phospholipin, but not by free cholesterol, oleic acid, castor or olive oil, glucose, Na K tartrate, Na citrate or lactate.

(B) Hyperthyroidic guinea-pigs are more susceptible to gastric ulcer formation by (I). (II) antagonises the thyroid effect.

(C) When (I) and diphtheria toxin are simultaneously injected into guinea-pigs the antagonistic ratio of (II) : (I) is 1 : 0.8. CH. ABS. (p)

**Influence of cell constituents of the pancreas on the external secretion of the pancreas. I. Influence of parenteral introduction of pancreas cell constituents into dogs with complete pancreatic fistulas. II. Influence of cell constituents of other organs. III. Influence of purified extracts of pancreas and other organs. IV. Mechanism of hypersecretion and nature of the exciting agent.** K. TABUCHI (*Japan. J. Exp. Med.*, 1934, **12**, 411—418, 419—421, 423—425, 427—435).—Pancreatic cell constituents and their purified extracts stimulate strongly the external secretion of the pancreas, independently of simultaneous secretion of gastric juice and bile. Secretion is not inhibited by atropine. The mechanism of stimulation differs from that of insulin and histamine and is effected by a hormone acting by way of the blood stream on the acinar cells. CH. ABS. (p)

**Action of some amines related to adrenaline: methoxyphenylmethoxyethylamines.** G. K. ELPHICK and J. A. GUNN (*J. Physiol.*, 1934, **81**, 422—433).—The physiological effects of *p*-methoxy-3 : 4-dimethoxy-, and 3 : 4 : 5-trimethoxy-phenyl- $\beta$ -methoxyethylamines are compared with corresponding compounds lacking OMe. Addition of OMe to the side-chain diminishes the activity. CH. ABS. (p)

**Importance of cholesterol in the action of calcium on heart muscle.** S. MENTL, J. KARASEK, and V. KRUTA (*Arch. int. Physiol.*, 1934, **40**, 158—172; *Chem. Zentr.*, 1935, **i**, 3158).—The heart of cholesterol-treated frogs reacts normally to Ca and adrenaline, although the isolated heart is abnormally sensitive in presence of cholesterol. The right auricle of cholesterol-fed guinea-pigs is more sensitive and contains more cholesterol than normal. G. H. F.

**Action of creatine on the double electric curve of fatigue in man.** G. BORGATTI (*Boll. Soc. ital. Biol. sperim.*, 1935, **10**, 609—611). R. N. C.

**Variations of the dehydroascorbic/ascorbic acid ratio in the liver and adrenals after administration of parasympatheticotropic substances.** F. COPELLO (Boll. Soc. ital. Biol. sperim., 1935, 10, 509—515).—The ratio is decreased by parasympathetic excitants, and increased by paralyzers, in the liver, but is not affected by either in the adrenals.

R. N. C.

**Theory of narcosis.** N. V. LAZAREV (Biochem. Z., 1935, 283, 158).—Claim of priority in respect of the work of Meyer and Hemmi (A., 1935, 893).

P. W. C.

**Effects of chloral hydrate on maternal and fetal organisms.** R. E. CAMPBELL (Amer. J. Obstet. Gynecol., 1934, 28, 83—88).—Chloral hydrate depresses respiration and urinary output.

CH. ABS. (p)

**Carbohydrate metabolism under barbiturate narcosis.** M. G. MULINOS (Arch. int. Pharmacodyn. Ther., 1934, 47, 111—112; Chem. Zentr., 1934, ii, 3403).—Blood-sugar (I) in rabbits and dogs is raised by amylal, pernocton (II), nembutal (III), and dial. (II) anaesthesia does not affect the action of subcutaneously-injected glucose, adrenaline, or insulin on (I). Oral administration of glucose to anaesthetised rabbits raises (I) to only 60% of the val. reached in unanaesthetised animals. The urine of (III)-anaesthetised cats contains a reducing substance that is not glucose.

R. N. C.

**Constitution and hypnotic action: bromoethyl- and diethyl-barbituric acid.** L. DONATELLI (Arch. Farm. sperim., 1935, 40, 497—516).—The Na salt of 5-bromo-5-ethyl- (I) has a stronger hypnotic action than that of 5:5-diethyl-barbituric acid (II), and is very toxic. In restricting the respiration, and is very toxic. In restricting the respiration, and diminishing the amplitude and the frequency of the cardiac function, and in vasodilatory action the effect of (I) is much > that of (II).

E. P.

**Effect of oxygen in the prevention of liver necrosis produced by volatile antiseptics.** S. GOLDSCHMIDT, I. S. RAVDIN, and B. LUCKÉ (Amer. J. Med. Sci., 1935, 189, 155—156).—In  $\text{CHCl}_3$  or ivinyl ether anaesthesia,  $\text{O}_2$  decreases subsequent necrosis.

CH. ABS. (p)

**Local anaesthetics with vasopressor action. Esters of aryethanolamines.** G. A. ALLES and R. K. KNOEFEL (Arch. int. Pharmacodyn., 1934, 47, 96—110; Chem. Zentr., 1934, ii, 3404).

R. N. C.

**Effects of drugs on the autonomic nervous and on protein metabolism in normal and hypophysectomised dogs.** Y. TAKIZAKI (Sci. Med. J., 1934, 53, No. 11, 98—117).—In action eserine increased protein and intermediate metabolism. The effect was reversed by administration of nicotine or atropine.

CH. ABS. (p)

**Action of decamethylenediguanidine bitartrate on blood-sugar.** B. L. MONIAS (Illinois Med. J., 1934, 66, 105—107).—Dosages of 12 mg. administered by stomach tube caused a temporary increase of blood-sugar. Larger amounts (24 mg.) caused convulsions and death even when glucose (I) was given after

convulsions started. Simultaneous injection with (I) was non-toxic.

CH. ABS. (p)

**Cardiazol as a reviver in animal experiments.** M. H. FISCHER and H. LOWENBACH (Klin. Woch., 1934, 13, 1401; Chem. Zentr., 1934, ii, 3983).

R. N. C.

**Carioclastic crisis in the reticulo-endothelial system and endogenous uric acid exchange.** G. DOMINI (Boll. Soc. ital. Biol. sperim., 1934, 9, 1297—1300).—Carioclastic substances do not affect blood- or urinary uric acid in the dog, but allantoin excretion is increased.

R. N. C.

**Comparison of the effect of guanidine, synthalin, and "anticoman" on the muscle of cold-blooded animals.** R. RITTMANN and J. MAGERL (Arch. Verdauungskr., 1935, 57, 9—14; Chem. Zentr., 1935, i, 3158).—The fatigue induced in frog sartorius muscle, indicated by the acceleration in rate of production of lactic acid, gives the order: synthalin > guanidine > "anticoman" > "anticoman" + pancreatic enzyme prep. > "anticoman" tablets.

G. H. F.

**Action of ricin on the isolated heart of the rabbit.** R. ATTIMONELLI (Boll. Soc. ital. Biol. sperim., 1933, 8, 1524—1528).

R. N. C.

**Action of thevetin, a cardiac glucoside, and its clinical application.** H. L. ARNOLD, W. S. MIDDLETON, and K. K. CHEN (Amer. J. Med. Sci., 1935, 189, 193—206).—Thevetin from "be-still" nuts (*Thevetia neriifolia*) has a digitalis-like action with potency and toxicity approx. 1/7 of that of ouabain.

CH. ABS. (p)

**Mechanism and course of chemotherapeutic action.** F. AXMACHER (Arch. exp. Path. Pharm., 1936, 180, 142—166).—The action of various chemotherapeutic substances is ascribed to purely physical processes, e.g., changes in permeability and surface action, resulting in exclusion of nutritive substances from the cell and in inhibition of cell-enzymes. The action of germanin (I) on the fermentation of cell macerates does not depend on adsorption-inactivation of zymase, but is possibly related to the presence of  $\text{SO}_3\text{H}$  in (I); that of Sb preps. is due to inhibition or destruction of carboxylase. The mechanism of curative processes is discussed.

F. O. H.

**Mode of action of chemotherapeutics in spirochaete and protozoan infections.** E. SINGER (Med. Klinik, 1935, 31, 380—389).

R. N. C.

**New antipyretic: isopropylantipyrene.** G. ORESTANO (Boll. Soc. ital. Biol. sperim., 1935, 10, 470—473).

R. N. C.

**Pharmacology of chenopodium oil. II.** M. AIAZZI-MANCINI and L. DOVATELLI (Boll. Soc. ital. Biol. sperim., 1934, 9, 1306—1307).

R. N. C.

**Theosan and its combinations.** F. ECKHARDT (Wien. med. Woch., 1934, 84, 1059; Chem. Zentr., 1934, ii, 3787).

R. N. C.

**Mechanism of the action of ephedrine on gaseous exchange.** G. ORESTANO (Boll. Soc. ital. Biol. sperim., 1935, 10, 467—469).—The action of ephedrine on gaseous metabolism is similar to that of

adrenaline, and is effective in the same species, the effect persisting longer. R. N. C.

**Octaverine, a new spasmolytic.** P. ELLINGER, W. KOSCHARA, and H. SEEGER (Arch. int. Pharmacodyn. Thé., 1934, 48, 50—62; Chem. Zentr., 1934, ii, 3402).—Octaverine, a derivative of phenylisoquinoline, is less toxic and is less rapidly absorbed and detoxicated than papaverine. R. N. C.

**Action of bulbocapnine on the frog's heart.** F. M. CHIANCONE and U. POPPI (Boll. Soc. ital. Biol. sperim., 1935, 10, 573—575). R. N. C.

**Action of bulbocapnine on isolated frog muscle.** U. POPPI and F. M. CHIANCONE (Boll. Soc. ital. Biol. sperim., 1935, 10, 570—573). R. N. C.

**Action of cocaine on fish.** R. DE MARCO (Boll. Soc. ital. Biol. sperim., 1933, 8, 1488—1490). R. N. C.

**Pharmacology of physostigmine.** C. R. LINEGAR, J. M. DILLE, and T. KOPPANYI (Science, 1935, 82, 497). L. S. T.

**New active principle in ergot: effects on uterine mobility.** M. E. DAVIS, F. L. ADAIR, G. ROGERS, M. S. KHARASCH, and R. R. LEGAULT (Amer. J. Obstet. Gynecol., 1935, 29, 155—167).—A yellow, stable, non-alkaloidal fraction is isolated. It provokes the characteristic uterine response. CH. ABS. (p)

**Physiological action of ergometrine and of ergometrine.** R. HAMET (Compt. rend. Soc. Biol., 1935, 120, 1208—1212).—The activity of ergometrine in the dog is the smaller. R. N. C.

**Effect of morphine and of heroin on blood-sugar and respiration in rabbits.** H. GYOKU (J. Chosen Med. Assoc., 1935, 25, 222—226).—Blood-sugar is increased by injection of morphine hydrochloride (0.05 g. per kg.), reaching a max. in 2—3 hr., and regaining normal in 6—7 hr. Heroin hydrochloride produces similar but smaller changes. CH. ABS. (p)

**Antagonism between nicotine and some quaternary hexamethylenetetramine iodides. Curare poisons.** J. GAUTRELET and N. HALPERN (Arch. int. Pharmacodyn. Thé., 1934, 47, 4—44; Chem. Zentr., 1934, ii, 3402). R. N. C.

**Effect of nicotine on sex and sexual hormone.** Y. C. LEE (Trans. Soc. Path. Japon, 1934, 24, 446—449).—Luteo-hormone had a marked antidotic action to nicotine. CH. ABS. (p)

**Action of pilocarpine and acetylcholine, introduced into a Vella loop, on enteric secretion.** G. SARZANA (Boll. Soc. ital. Biol. sperim., 1935, 10, 542—544). R. N. C.

**Action of pilocarpine on formation of lactic acid and breakdown of phosphagen in the isolated frog's muscle at rest.** D. NACHMANSOHN, J. WAJZER, and R. LIPPMANN (Compt. rend. Soc. Biol., 1936, 121, 139—141).—Pilocarpine accelerates both lactic acid formation and phosphagen breakdown in the isolated muscle in anaërobiosis. R. N. C.

**Tolerance of cells cultivated *in vitro* to the action of quinine dichloride.** L. PILATI (Boll. Soc. ital. Biol. sperim., 1935, 10, 414—416). R. N. C.

**Influence of quinine derivatives on the iodine contents of endocrine organs.** II. A. OHTA (Sei-i-Kwai Med. J., 1934, 53, No. 11, 78—97).—Quinine hydrochloride (10 c.c. of 10% solution per kg.) increased the I content of thyroid, adrenals, liver, ovaries, and testicles, and lowered that of blood, thymus, spleen, pituitary, and pancreas. Both cinchonine hydrochloride and 2-hydroquinine produced smaller increases in I in thyroid, adrenals, and testicle; the former lowered that of spleen, and the latter that of spleen and liver. Optoquin caused no changes (cf. A., 1935, 1396). CH. ABS. (p)

**Action of quinic and phenylcinchoninic acids on metabolism.** E. BECCARI (Boll. Soc. ital. Biol. sperim., 1935, 10, 402—405).—Injection of quinic (I) and phenylcinchoninic acids (II) in healthy human subjects increases uric acid excretion. (I) produces a negative and (II) a positive balance of N and P. The urinary urea-/total N ratio is reduced by (I) through an increase of non-urea-N excretion, whilst the variations produced by (II) are due to variations of urea. The azoturic coeff. is reduced by both acids. R. N. C.

**Alkaloids from the seeds of *Cassia absus*, Linn.**—See this vol., 350.

**Isomerisation of conessine and its nor-bases.**—See this vol., 350.

**Variable action of cobra venoms standardised for therapeutic use.** P. SEMOMIN and J. BRION (Compt. rend. Soc. Biol., 1935, 120, 1253—1255). R. N. C.

**Ultra-violet absorption spectra of snake venoms.** H. F. HOLDEN and C. G. SETTER (Austral. J. Exp. Biol., 1936, 13, 223—228).—The venoms of many snakes exhibit an ultra-violet absorption band at about 280 m $\mu$ , but no correlation exists between the toxicity of the venom and the position or intensity of the band. W. O. K.

**Carbon tetrachloride intoxication.** A. NASSAN and M. SALAH (J. Egypt. Med. Assoc., 1935, 18, 207—214).—Poisoning by CCl<sub>4</sub> used as an anthelmintic is not related to the amount used or to Ca deficiency, but is due to constitutional intolerance. CH. ABS. (p)

**Arrow poisons.** C. G. SANTESSON (Skand. Arch. Physiol., 1934, 70, 102—125; Chem. Zentr., 1935, i, 3310).—An arrow poison of central African pigmies is of the digitalis-strophanthus type. Investigation of two Celebes arrow poisons points to their glucosidic nature, one of them possibly being derived from *Antiaris toxicaria*, Lesch. H. N. R.

**Physiology of the treatment of barbiturate poisoning.** R. MASSIERE and G. BEAUMONT (Presse Méd., 1935, 43, 4—7; Chem. Zentr., 1935, i, 3310).—The efficacy of strychnine as an antidote for barbiturate poisoning is not due to antagonism, but is an adsorption effect analogous to the toxin-antitoxin reaction. H. N. R.

**Toxicity of methyl alcohol.** S. KAJIZUKA (J. Soc. Chem. Ind. Japan, 1935, 38, 746—747B).—MeOH stimulates the mucous membranes locally, but is not highly toxic. On a diet containing 10% MeOH,

rats show a turbidity of the urine and an increased excretion of  $\text{HCO}_2\text{H}$ . H. G. R.

**Cause of the toxicity of methyl alcohol.** I. SIMON (Boll. Soc. ital. Biol. sperim., 1935, 8, 1376—1379).—The toxic effect of  $\text{MeOH}$  is considered to be due to  $\text{MeOH}$  itself, no oxidation to  $\text{CH}_2\text{O}$  or  $\text{HCO}_2\text{H}$  occurring in the body. R. N. C.

**Distribution of arsenic a few hours after ingestion of small amounts.** G. VITTE (Bull. Trav. Soc. Pharm. Bordeaux, 1934, 72, 357—358; Chem. Zentr., 1935, i, 3159).—The distribution of As in the viscera with and without simultaneous dosing with  $\text{Na}_2\text{SO}_4$  has been investigated. J. S. A.

**Effect of Fowler's solution on animals.** E. ROBERTS and W. M. DAWSON (Illinois Agric. Exp. Sta. Bull., 1935, No. 413, 187—202).—The practice of feeding Fowler's solution to animals for show purposes diminishes respiratory activity and reproductive functions. In treated animals As may be detected in the urine, faeces, and hair. A. G. P.

**Increase in toxicity for mice of solutions of neoarsphenamine on exposure to air.** R. WIEN (Quart. J. Pharm., 1935, 8, 631—641).—The toxicity to rats of a solution of neoarsphenamine increased by 17.5 and 23% after exposure to air for 15 and 25 min., respectively, but this increase was prevented if the solution was protected by a layer of liquid paraffin. W. O. K.

**Toxicity of sodium cyanide and the efficiency of the nitrite-thiosulphate combination as a remedy for poisoned animals.** A. B. CLAWSON, v. F. COUCH, and H. BUNYEA (J. Washington Acad. Sci., 1935, 25, 357—361).— $\text{NaCN}$  is less toxic than  $\text{KCN}$  or  $\text{HCN}$ , whilst the two latter are similar. The ratio min. toxic/min. lethal doses is 1 : 2 for  $\text{KCN}$  and  $\text{HCN}$ , and 1 : 1.25 for  $\text{NaCN}$ . Intraperitoneal injection of 1 g. of  $\text{NaNO}_2$  and 2 g. of  $\text{Na}_2\text{S}_2\text{O}_3$  in  $\text{H}_2\text{O}$  1.5—4 min. after the  $\text{NaCN}$  effected recovery in 4 out of 7 cases. P. G. M.

**Use of sodium tetrathionate in cyanide poisoning.** E. MENEGETTI (Boll. Soc. ital. Biol. sperim., 35, 10, 386—391).—A criticism of the method of Aunsiechio and de Nito (cf. A., 1935, 1276). R. N. C.

**Treatment of cyanide poisoning of sheep and cattle.** H. BUNYEA (J. Amer. Vet. Med. Assoc., 656—661).—Injections of methylene-blue,  $\text{NaNO}_2$ , and  $\text{Na}_2\text{S}_2\text{O}_3$  had some val. 10 c.c. of  $\text{NaNO}_2$  followed immediately by 20 c.c. of 10%  $\text{Na}_2\text{S}_2\text{O}_3$  was preferable to either alone. CH. ABS. (p)

**acid and soaps are not antidotes for cyanide poisoning.** BELLECCI (Arch. Farm. sperim., 1935, 40, 517—533).—If intravenous injection of the min. lethal dose  $\text{HgCl}_2$  is followed by injection of tannic acid or Na oleate (II) death is not prevented; is retarded by small, accelerated by large, doses of (I) or (II). If  $\text{HgCl}_2$  is given *per os*, (I) or (II) (*per ven* in large excess retards but does not prevent death. E. P.

**Diagnosis of lead poisoning in children.** M. (Klin. Woch., 1934, 13, 1646—1647; Zentr., 1935, i, 3320).—X-Ray examination,

supplemented by the skin reaction with  $\text{Na}_2\text{S}$ , is best. H. N. R.

**Action of electromagnetic waves on enzyme systems.** A. DE P. FORJAZ (Biochem. Z., 1935, 283, 53—58).—Electromagnetic waves have no effect on the activity of fumarase, but increase the activity of the phosphatase of takadiastase by 20%. P. W. C.

**So-called "blood-group enzyme" content of saliva.** O. SIEVERS (Klin. Woch., 1934, 13, 1640—1641; Chem. Zentr., 1935, i, 3148).—The power of saliva to destroy blood-group characteristics is greatest when collected during starvation. G. H. F.

**Enzymic reactions in heavy water.** D. L. FOX (J. Cell. Comp. Physiol., 1935, 6, 405—424).—Catalase, amylase, and emulsin show no loss of activity in  $\text{D}_2\text{O}$  at the same temp. and  $p_{\text{H}}$  as controls in  $\text{H}_2\text{O}$ . The activity of amylase appears to be increased in conc.  $\text{D}_2\text{O}$ . R. N. C.

**Enzymic hydrolysis of glucosides in heavy water.** K. F. BONHOEFFER and F. SALZER (Naturwiss., 1935, 23, 867).—Glucosides with high affinities for emulsin (*e.g.*, salicin) are hydrolysed more slowly in  $\text{D}_2\text{O}$  than in  $\text{H}_2\text{O}$ , whilst for those with low affinities (*e.g.*, methylglucoside) the reverse is the case.  $\text{D}_2\text{O}$  retards the hydrolysis of the enzyme-substrate complex, but may also increase the affinity of the enzyme for its substrate, in which case the higher concn. of the enzyme-substrate complex may compensate for the retardation of the hydrolysis, leading to an increase in the rate of reaction. E. A. H. R.

**Hydrogen-transporting co-enzyme, its composition and mode of action.** O. WARBURG, W. CHRISTIAN, and A. GRIESE (Biochem. Z., 1935, 282, 157—205).—The co-enzyme (I) from red blood cells, which is designated the H-transporting enzyme, was purified until its catalytic activity could not be further increased. The purest prep. (12.9% N, 12.3% P) was readily sol. in  $\text{H}_2\text{O}$ , did not crystallise, and on hydrolysis yielded 1 mol. each of adenine and nicotinamide together with 3 mols. of  $\text{H}_3\text{PO}_4$  and 2 mols. of pentose. Assuming that these are united with the loss of  $6\text{H}_2\text{O}$ , (I) is  $\text{C}_{21}\text{H}_{28}\text{O}_{17}\text{N}_3\text{P}_3$ . The  $\text{H}_2$  transportase of heart-muscle is probably, and that of yeast is certainly, identical with (I). (I) cannot replace cozymase (II) in yeast fermentation nor can (II) replace (I) in oxidation experiments. (I) is however, probably closely related to (II). (I) is active only in association with certain proteins, which are called intermediate enzymes (III). Hexosephosphoric acid (IV) in presence of traces of (I) + (III) + Warburg's yellow enzyme (V) is oxidised to hexosephosphonic acid (VI), (V) being reduced and, in presence of atm.  $\text{O}_2$ , reoxidised. (IV) is also oxidised by an equiv. amount of (I) in presence of (III), giving (VI) + (I)- $\text{H}_2$ , the latter then being able to react with (V) to give free (I) + (V)- $\text{H}_2$ . This then reacts with atm.  $\text{O}_2$  giving  $\text{H}_2\text{O}_2$  + (V). (I) can be hydrogenated reversibly by  $\text{Na}_2\text{S}_2\text{O}_4$  and irreversibly by  $\text{Pt} + 3\text{H}_2$ . In the latter reaction the  $\text{C}_5\text{H}_5\text{N}$  is converted into a piperidine ring and (I) loses its activity. The reversible hydrogenation of (I) is a partial hydrogenation of the  $\text{C}_5\text{H}_5\text{N}$  ring. P. W. C.

**Destruction of hydrogen transporting co-enzyme by ultra-violet light.** O. WARBURG and W. CHRISTIAN (Biochem. Z., 1935, 282, 221—223).—When 0.001 mg. of co-enzyme (I) in 1 c.c. of  $H_2O$  is irradiated in a quartz vessel at a distance of 30 cm., the activity of (I) is lost in 15 min. Irradiation in a glass vessel or of more conc. solutions (1 mg. per c.c.) in quartz vessels does not result in detectable loss in 15 min. Using dil. solutions, the time for half-destruction of (I) increases rapidly with the  $\lambda$ , being 520 times as great at 283  $m\mu$  as at 186  $m\mu$ .

P. W. C.

**Constitution of the prosthetic group of catalase.** K. G. STERN (J. Biol. Chem., 1936, 112, 661—669; cf. A., 1935, 1278).—Catalase (I) solutions from horse liver after an  $Al_2O_3$  gel adsorption were further conc. by  $COMe_2$ - $CO_2$  treatment. The (I) solution is then sufficiently conc. to allow the cleavage of (I) by the acid- $COMe_2$  treatment used for respiratory haem pigments, which ppts. the protein. On removal of the  $COMe_2$  the prosthetic group of (I) is pptd. The identity of this prosthetic group with the protohaematin of haemoglobin is established by the prep. from it of a mesoporphyrin  $Me_2$  ester and by its conversion into the haemoglobin of the same species by the substitution of native globin for the enzyme-protein.

E. A. H. R.

**Nutritive value of pentosans. V. Digestion by intestinal enzymes.** H. IWATA (J. Agric. Chem. Soc. Japan, 1935, 11, 1024—1027).—Xylanase occurs in rabbit's and pig's intestine to an extent < that of co-existing amylase. Optimum temp. and  $p_H$  are 38° and 6, respectively.

F. O. H.

**Action of lithium, sodium, and potassium bromides and iodides on the activity of the amylase of the fowl's crop. VII, VIII.** A. BERNARDI and M. A. SCHWARZ (Giorn. Biol. Appl. Ind. Chim., 1932, 2, 41—52; Chem. Zentr., 1935, i, 3679).— $LiBr > KBr > NaBr$  stimulates the amylase activity; otherwise they behave similarly to the chlorides.  $LiI < KI < NaI$  inhibits the activity.

R. N. C.

**Technique of diastase determination in blood according to Ottenstein.** J. BRINCK (Klin. Woch., 1934, 13, 1686—1688).—The technique is described and possible sources of error are discussed.

R. N. C.

**Relation of glycolysis to proteolysis in tissues.** V. M. RUBEL (Biochem. Z., 1936, 283, 180—189).—In healthy and diseased (tumour) tissue, glycolysis, increased by addition of glucose,  $AcCO_2H$  (I), and  $MeCHO$  or decreased by addition of  $NaF$  is accompanied, respectively, by increased or decreased proteolysis. Lactic acid (II) increases proteolysis and is probably the link which connects the two processes. When production of (II) is restricted by  $NaF$  the extent of proteolysis is restored to normal by addition of (I) and (II).

W. McC.

**Conversion of *p*-tolylglyoxal into *l*-*p*-methyl-mandelic acid by the enzyme of fresh cells.** S. FUJISE and M. IWAKIRI (Biochem. Z., 1936, 283, 298—300).—Fresh carp-muscle extract converts *p*-tolylglyoxal almost quantitatively into *l*-*p*-methyl-mandelic acid. The conversion of  $BzCHO$  into *l*-

mandelic acid by the extract is more rapid, but not so complete.

W. McC.

**Complete enzymic hydrolysis of chondroitin- and mucoitin-sulphuric acid.** C. NEUBERG and W. CAHILL (Atti R. Accad. Lincei, 1935, [vi], 22, 149—155).—Enzyme preps. from *B. fluorescens* hydrolyse chondroitinsulphuric acid to glucuronic acid (I), chondrosamine,  $AcOH$ , and  $H_2SO_4$  and mucoitinsulphuric acid to (I), glucosamine,  $AcOH$ , and  $H_2SO_4$ .

F. O. H.

**Glucosulphatase. XII. Purification of the enzyme and the effects of phosphate, sulphate, and fluoride on the enzyme action.** T. SODA and F. EGAMI (J. Chem. Soc. Japan, 1934, 55, 1164—1168).—Activity of the enzyme is inhibited by  $PO_4'''$  and  $F'$  in concns.  $> 0.0005M$  (cf. A., 1935, 659).

CH. ABS. (p)

**Pancreatic lipase. I. II. Influence of various compounds on the hydrolytic activity.** S. S. WEINSTEIN and A. M. WYNNE (J. Biol. Chem., 1936, 112, 641—648, 649—660).—I. The rate of hydrolysis of glycerides and alkyl esters of fatty acids by pancreatic lipase (I) is investigated. The initial rate of hydrolysis of triglycerides decreases in the order tripalmitin (II), tributyrin, trihexoin, triacetin, trivalerin. The initial rates of acid formation from mono-,  $\alpha\gamma$ -di-, and tri-acetin are in the ratio 1 : 2 : 2.66, indicating that the ester linking on the  $\beta$ -C is more slowly hydrolysed than the two end linkings. The rate of hydrolysis of the alkyl esters of the fatty acids increases with the length of the C chain of the acid radical, but decreases with its length in the alkyl. With phosphate buffers the initial rate of hydrolysis of (II) and of  $PrCO_2Me$  is greatest at  $p_H$  7.2, but in glycine buffers the optimum  $p_H$  is 9.3. The initial velocity of hydrolysis  $\propto$  (I) concn. and (II) concn. (in the range 0.016—0.16*M*). The vals. did not accord with the Michaelis equation.

II. Ketones and aldehydes markedly inhibit (I). The degree of inhibition depends on the time of preliminary incubation of (I) with the inhibitor, the mol. vol., the no. of CO groups present, and the presence or absence of the  $C_6H_5$  ring. Heavy metals are inhibitory.  $CN'$  and  $SH$  compounds activate (I). Phenols and cresols are inert, but a  $NO_2$ -group increases the toxicity. Di- but not tri-hydric phenols are inhibitory; the inhibitory action of the former increases with increased separation of the OH groups. Monohalogen derivatives of  $AcOH$  inhibit in the order  $I > Br > Cl$ , and halides in the order  $F > I > Br > Cl$ . Bile salts in neutral solution are without effect. Possible mechanisms of some of the inhibitions and activations are discussed, and it is suggested that  $NH_2$  may be an essential constituent of (I).

E. A. H. R.

**Castor bean lipase. VII. Relation between activity of highly active *Ricinus* lipase and some oxidising and reducing substances.** E. TAKAMURA (J. Agric. Chem. Soc. Japan, 1935, 11, 156; cf. A., 1935, 1416).—Exposure to air or  $H_2O_2$  retarded the activity of the lipase. Glutathione (I) accelerated activity to extents  $\propto p_H$ . Larger proportions of (I) or adjustment of  $p_H$  to 6.0 had a

retarding action. Cysteine (II),  $\text{CH}_2\text{O}$ , glucose, fructose, and  $\text{NaHSO}_3$  produced similar effects, but cystine had no action. Lipase, inactivated by oxidation, was not regenerated by addition of (I) and (II). CH. ABS. (p)

**Inhibitory action of formaldehyde on the activity of blood choline-esterase.** E. CORTEGGIANI, J. GAUTRELET, N. HALPERN, and A. SERFATY (Compt. rend. Soc. Biol., 1936, 121, 316—318).— $\text{CH}_2\text{O}$  inhibits the action of choline-esterase after a latent period which  $\propto$  the dilution of the  $\text{CH}_2\text{O}$ . The inhibition is probably the result of alterations of  $p_H$ . R. N. C.

**Formation of acetylcholine in the body, and an investigation of the choline-esterase. I—III.** F. H. SHAW (Austral. J. Exp. Biol., 1935, 13, 251—260).—Stimulation of the lingual nerve of the dog does not alter the choline content of the tongue. Two esterases exist in serum, of which only one is inhibited by eserine. In presence of pig's serum, acetylcholine (I) is synthesised from choline and  $\text{NaOAc}$ . Neither this action nor the enzymic synthesis of tributyrin is inhibited by eserine. The synthesis of (I) in the body is probably effected through the synthetic action of tissue-esterase. W. O. K.

**Enzymic histochemistry. I. Distribution of arginase activity in rabbit kidney.** L. WEIL and J. O. ELY (J. Biol. Chem., 1936, 112, 565—577).—The micro-method of Linderström-Lang *et al.* (A., 1935, 1163) for determining arginase (I) activity is suitable for histo-enzymic studies if the solution is buffered at  $p_H$  9.5. A micro-(I) unit is defined. (I) activity is present in the cortex only of rabbit kidney, and runs parallel with the no. of proximal convoluted tubular cells. The medulla shows no (I) activity, and as addition of inactive medullary tissue to cortical tissue causes no inhibition of (I) activity in the latter, it is concluded that the inactivity of the medulla is not due to inhibitors. E. A. H. R.

**Assay of aspartase.** K. P. JACOBSON and M. C. RES (Compt. rend. Soc. Biol., 1936, 121, 251—255).—Experiments described do not establish the presence of aspartase in the vegetable tissues examined, nor the amination of fumaric acid as a regular metabolic reaction in plants. R. N. C.

**Effect of various salts on the aspartase system.** F. B. PEREIRA and M. SOARES (Compt. rend. Soc. Biol., 1936, 121, 255—258).—Synthesis of acid by aspartase is accelerated by  $\text{SO}_4^{2-}$  and retarded by  $\text{Cl}^-$  relative to  $\text{Cl}^-$ . Atoxyl does not affect the action in presence of  $\text{PO}_4^{3-}$  buffer, but morphine slows it.  $\text{PO}_4^{3-}$  buffer alone exerts a restraining action, as does  $\text{Na}^+$  in presence of  $\text{Cl}^-$ . R. N. C.

**Peptic hydrolysis of caseinogen.** L. UTKIN (Biochem. Z., 1936, 283, 233—240).—In the early hydrolysis the liberation, at  $p_H$  4.6, of organic P compounds occurs in two (possibly more) defined phases. The P:N ratio of the compounds produced in the first phase differs from that of those produced in the second, the difference being due to differences in the composition of the

compounds, and not merely to differences in the amounts. W. McC.

**Physiology of digestion of plankton Crustaceæ. I. Digestive enzymes of *Daphnia*.** A. D. HASLER (Biol. Bull., 1935, 68, 207—214).—The  $p_H$  of the intestine of *D. magna* varied from 6.8 at the anterior to 7.2 at the posterior end. Tryptic digestion of casein is indicated. Glycerol extracts of the intestine digested gelatin. Hog-pancreas extract gave a similar hydrolysis curve. Extracts of defatted *D. pulex* contained amylase and lipase. CH. ABS. (p)

**Multivalent amino-acids and peptides. VI. Action of proteolytic enzymes on synthetic substrates.** J. P. GREENSTEIN (J. Biol. Chem., 1936, 111, 517—522; cf. this vol., 194).—Anhydro-*l*-lysyl-*l*-glutamamide,  $[\alpha]_D^{25} - 27.7^\circ$ , is unaffected by pepsin, trypsin, or papain-HCN (also without action on anhydro-*dl*-aminotricarballylic tetra-amide), which is inconclusive evidence against the existence of diketopiperazine rings in proteins. *l*-Lysyl-*l*-glutamamide and *l*-histidine are hydrolysed by yeast peptidase, the former more slowly. Glycyl-*dl*-aminotricarballylic acid is slowly split by yeast autolysate and intestinal erepsin, but not by carboxypeptidase. R. S. C.

**Inhibition of enzymic proteolysis by oxidising agents. Nature of the action of potassium bromate and analogous substances as improvers of wheat flour. II.** H. JØRGENSEN (Biochem. Z., 1935, 283, 134—145).—The inhibition of proteinases (I) in flour- $\text{H}_2\text{O}$  suspensions by  $\text{KBrO}_3$  and the consequent decrease of solubility of flour-N are greatly emphasised on adding yeast, due to the activation of (I) by the glutathione of the yeast (cf. B., 1935, 1115). P. W. C.

**Action of enzyme extracts on soluble keratin.** P. G. CASTELLINO (Arch. Ist. Biochim. Ital., 1935, 7, 417—424).—Extract of rabbit's skin is free from enzymes hydrolysing sol. keratin [prepared by the action of Na thioglycollate (A., 1934, 1238)] at  $p_H$  1.5, 3, or 8, but contains a tryptic enzyme hydrolysing caseinogen. F. O. H.

**Enzymic synthesis from thyroid di-iodotyrosine peptone of an artificial protein which relieves myxœdema.** W. T. SALTER and O. H. PEARSON (J. Biol. Chem., 1936, 112, 579—589).—A solution of di-iodotyrosine peptone (I) was prepared by peptic digestion of thyroglobulin (II) of human origin, followed by removal of thyroxine (III). (I) was conc. and then subjected to a peptic synthesis, with the formation of an artificial protein containing I, analogous in its properties to a true protein. Clinically, in equiv. I dosage, it relieves myxœdema as effectively as (II). The view is held that di-iodotyrosine is the precursor of (III) and that a naturally occurring protease in the thyroid cells is possibly responsible for the synthesis. E. A. H. R.

**Phosphatase content of blood-serum and tissues in the rat following administration of vitamin-D and -A.** P. D. CRIMM and J. W. STRAYER (J. Biol. Chem., 1936, 112, 511—515).—The mean phosphatase (I) content of rat serum is about 20 times that of human serum. Toxic doses of viosterol (II) lead to a marked decrease of (I) activity in blood

and kidney, and a considerable increase in the small intestine. The effect of (II) on the high (I) content of bones is variable. Liver and spleen contain small amounts of (I) both before and after administration of (II). The decrease in serum-(I) with rats deficient in vitamin-A (III) or with hypervitaminosis-A is attributed to impaired nutrition rather to the presence or absence of (III). E. A. H. R.

**Plasma-phosphatase in normal and rachitic children.** O. ANDERSEN (Jahrb. Kinderheilk., 1935, 144, 206—221; Chem. Zentr., 1935, i, 3148).—Antirachitic treatment of rachitic children (technique of Kay) produces a diminution of plasma-phosphatase. G. H. F.

**Intestinal phosphatase.** H. G. K. WESTENBRINK (Arch. Neerland. Physiol., 1935, 20, 566—590).—The activity of a solution of intestinal phosphatase (I) is not  $\propto$  its concn., and the rate of hydrolysis of Na glycerophosphate continually decreases with time of reaction. This is not due to inhibition by  $H_3PO_4$  or glycerol, or to decreasing substrate concn. or to inactivation by the buffer of  $p_H$  8.8. The activity of (I)  $\propto$  concn. if it is previously kept in contact with the buffer for some hr. at  $25^\circ$ . In determining (I) by the hydrolysis of  $H_3PO_4$  from a suitable substrate, it is best to work in a medium containing Ca. J. N. A.

**Determination of the phosphatase activity of whole blood, plasma, and serum.** J. CAYLA (Bull. Soc. Chim. biol., 1935, 17, 1707—1714).—A modification of the Mo colorimetric method for the determination of phosphatase (I) is described. In the normal adult the (I) content is 15 units per litre of serum, 1 unit of (I) liberating 1 mg. of  $H_3PO_4$  from 10% aq. Na  $\beta$ -glycerophosphate at  $p_H$  7.6. A. L.

**Specific pyrophosphatase.** E. BAUER (Naturwiss., 1935, 23, 866—867).—Glycerol extracts of yeast retain their ability to act on pyrophosphate after the  $\alpha$ -glycerophosphatase activity has largely been destroyed by heat, indicating the separate existence of a sp. pyrophosphatase. E. A. H. R.

**Glycerophosphatase of the brain.** F. CEDRANGOLO (Boll. Soc. ital. Biol. sperim., 1935, 10, 374—376).—Brain-glycerophosphatase shows optimum activity at  $p_H$  5.32 and 9.16, with a max. in 0.0016M-glycerophosphate. Prolonged electrodialysis abolishes the enzyme activity, which is restored by  $MgCl_2$ . Activity is inhibited by NaF,  $CH_2I-CO_2H$ ,  $As_2O_3$ , and phloridzin. The enzyme shows a preference for  $\alpha$ -glycerophosphate. R. N. C.

**Mode of action of intermediate enzymes.** E. NEGELEIN and E. HAAS (Biochem. Z., 1935, 282, 206—220).—In the reaction, co-enzyme (I) + hexosediphosphoric acid = (I)· $H_2$  + phosphohexonic acid, which occurs in presence of intermediate enzyme (II), the velocity of hydrogenation can be determined in terms of the rate of the resulting increase of absorption in the ultra-violet at 345 m $\mu$ . A study of the hydrogenation velocities with varying amounts of (I) and (II) shows that (II) functions not as a catalyst, but as the colloidal carrier of (I). (I) and (II) by a reversible reaction are converted into the H-transporting enzyme (III). At a concn. of (I)

of  $10^{-5}$  mol. per litre, half of the (III) is dissociated into (I) + (II). As a result of such dissociation, a small amount of (II) can effect hydrogenation of large amounts of (I). (II) therefore differs from the carrier of the yellow enzyme (IV), since it is combined with (IV), and the oxidational reaction requires therefore a stoicheiometric amount of pigment.

P. W. C.

**Oxidation, phosphorylation, and fermentation by apozymase in presence of reversible oxidation-reduction systems.** A. LENNERSTRAND and J. RUNNSTROM (Biochem. Z., 1935, 283, 12—29).—Oxidation and phosphorylation are studied in a system containing apozymase, cozymase, hexose diphosphate, glucose, and either methylene-blue (I) or pyocyanin (II), fermentation being inhibited by NaF. The system absorbs  $O_2$ , but forms practically no  $CO_2$ . Although (I) and (II) belong to the same potential range, the  $O_2$  absorption with (II) is three times that with (I) and moreover using  $\alpha$ -naphthol-2-sulphonate-indophenol, which has a much higher potential, the  $O_2$  absorption is  $<$  with (II). There is a definite connexion between oxidation and phosphorylation, 1 mol. of glucose being esterified with  $PO_4$  for each mol. of phosphoglyceric acid produced by oxidation from triose phosphate. P. W. C.

**Formation of flavin enzyme systems in germinating seeds.** H. VON EULER and O. DAHL (Biochem. Z., 1935, 282, 235—241).—The total flavin (I) content of barley in the first 5 days of germination is 3—7 times that of oats. The (I) synthesis is completed in barley by the 2nd day, but continues longer in oats. In extracts of germinated seeds, the ratio of non-dialysable to total (I) is 2 : 3, and is maintained fairly const. during germination. In peas (ungerminated) which contain considerable amounts of (I), almost all the (I) is in the non-dialysable form. Tables summarise the accompanying increases in respiration during germination. P. W. C.

**Nicotinamide and lumino-flavin.** O. WARBURG and W. CHRISTIAN (Ber., 1936, 69, [B], 228; cf. Kuhn *et al.*, this vol., 227).—Nicotinamide has been obtained previously from co-enzyme (I) and lumino-flavin by irradiation of an alkaline flavin solution obtained from milk. Since the yellow enzyme and (I) are universal components of cells, Kuhn's discoveries are not fundamentally new. H. W.

**Fermentation velocity of hexosediphosphoric acid and phosphate transfer to adenylic acid.** P. OHLMEYER (Biochem. Z., 1935, 283, 114—127).—Although muscle-adenylic acid (I) is not identical with and cannot replace cozymase in all its reactions, yet (I) has an activating role in some fermentation reactions. Thus hexose diphosphate in yeast maceration juice with added (I) is partly fermented and partly converted into hexose monophosphate (II), whilst (I) is converted into adenylyl pyrophosphate (III), which is identical with muscle-(III). The higher is the concn. of (I) in this reaction, the greater is the max. velocity. The fermentation velocity of (II) is also increased, but to a smaller extent by addition of (I), and (III) is again formed. Addition of (III) has no effect on the velocity of fermentation of the diphosphate. P. W. C.

**Action of extracts of liver and other organs on fermentation by yeast.** J. DADLEZ and W. KOSKOWSKI (Biochem. Z., 1936, 283, 292—297; cf. Zipf *et al.*, 1935, 253).—The stimulating effect on fermentation by yeast of liver extract is > that of extract of other organs (spleen, stomach, lung, heart, muscle, kidney, brain, testes, uterus, mammary gland, bone-marrow, pituitary, thymus, adrenals). With liver and spleen extracts the action does not always run parallel with the anti-anæmic effect. W. McC.

**Mechanism of oxidation processes.** XLIII. **Arrest of the respiration and fermentation processes of yeast.** H. WIELAND, K. RAUCH, and A. F. THOMPSON (Annalen, 1936, 521, 214—226).—The inhibiting action of various poisons on the fermentative action (glucose) of "impoverished" yeast is generally smaller than that on the aerobic dehydrogenation of EtOH at 30° and  $p_H$  6.8. 0.0002*M*-KCN reduces the  $O_2$  consumption to 56%, but 30 times this concentration is necessary to effect an equal retardation of the fermentation process.  $Na_2S$  is similar, but  $NaCNO$ , which is more potent than KCN, inhibits both processes to approx. the same extent;  $NaN_3$ , which inhibits the dehydrogenation as effectively as does KCN, has actually a small accelerating influence on the fermentation, and is equally effective under  $O_2$  as under  $N_2$ . The catalase activity is inhibited by  $NaCNO > NaN_3 > KCN$ . The inhibiting action of these poisons is largely removed by centrifuging the yeast with  $H_2O$ . The  $O_2$  consumption in the aerobic dehydrogenation of EtOH is greatly reduced if the  $[O_2]$  is only 2—5% (cf., A., 1932, 303). J. W. B.

**Effect of selenium on cellular metabolism.** **Rate of oxygen uptake by living yeast in presence of sodium selenite.** V. R. POTTER and C. A. ELVEHJEM (Biochem. J., 1936, 30, 189—196).—The uptake in presence of glucose, fructose, and mannose is diminished by 80% when  $Na_2SeO_3$  (min. effective concn. 0.0033*M*) is added. With lactate and pyruvate as substrates, the diminution is < 10%. The oxidation by yeast of EtOH, AcOH, and possibly succinic acid also appears to be diminished by  $Na_2SeO_3$ . The action is in all cases most marked in the acid zone and decreases rapidly at  $p_H$  7.0—7.5. Se appears to act primarily as inhibitor of glycolysis.  $a_3AsO_3$  (min. effective concn. 0.001*M*) is more toxic to oxidative systems than is  $Na_2SeO_3$ . W. McC.

**Effect of *m*-dinitrobenzene and its reduction derivatives on the metabolism of Fleischmann's yeast.** REAC'H (Compt. rend. Soc. Biol., 1936, 121, 248).—Respiration of liquid-cultured yeast is increased considerably by  $m\text{-NO}_2\text{-C}_6\text{H}_4\text{-NO}$  (I) and by  $m\text{-C}_6\text{H}_4(\text{NO}_2)_2$  (II), whilst that of yeast is increased considerably by both possibly through the reduction of (II) to (I) by the organism.  $m\text{-NO}_2\text{-C}_6\text{H}_4\text{-NH-OH}$  does not affect respiration. R. N. C.

**Action of dinitrothiophen on the metabolism of Fleischmann's yeast.** P. CREAC'H (Compt. Rend. Soc. Biol., 1936, 121, 248—250).—Dinitrothiophen is irreversibly after a period of latency  $\propto$  the concn. Respiration of the yeast

risers temporarily when reduction begins, afterwards falling rapidly to < the initial val. R. N. C.

**Catalytic fermentation of some fructoholosides.** R. GUILLEMET (Compt. rend., 1935, 201, 1517—1519).—Raffinose, gentianose, stachyose, and levosin are fermented by yeast juice to the extent of 100, 66, 50, and 30%, but in the absence of von Euler's Z factor fermentation is much reduced and levosin is not fermented. J. L. D.

**Action of methyl and ethyl alcohol on enzymes.** I. **Action on beer yeast and on the cytoplasm of castor seeds.** N. T. DELEANO and D. MEZINCESCO (Bull. Soc. Chim. biol., 1935, 17, 1805—1813).—Small quantities of MeOH and EtOH increase slightly the rate of carbohydrate fermentation by yeast, but larger amounts inhibit the reaction, MeOH being less toxic. The inhibition of lipase action by MeOH and EtOH is almost the same, but is more marked with olive oil than with castor oil as substrate. A. L.

**Yeast lipins.** III. **Lecithin and kephalin.** L. F. SALISBURY and R. J. ANDERSON (J. Biol. Chem., 1936, 112, 541—550).—The mixed phospholipins of yeast have been separated into lecithin (I) and kephalin (II). (I) was obtained free from  $NH_4-N$  and all the N of (II) was in the  $NH_2$ -form. On hydrolysis (I) gave a mixture of fatty acids, 86% of which were liquid, optically active glycerophosphoric acid (III), and choline, whilst (II) gave a similar mixture of acids, 84% of which were liquid, optically inactive (III), and  $NH_2\text{-CH}_2\text{-CH}_2\text{-OH}$ . The liquid component acids of both (I) and (II) gave a mixture of palmitic (IV) and stearic (V) acids on catalytic reduction. The solid acids consisted only of (IV) and (V). Methods of prep. of hydrolecithin and hydrokephalin are given. E. A. H. R.

**Biological value of two *Torula* from the cheese factory.** G. GUITTONNEAU and H. SIMONNET (Compt. rend. Soc. Biol., 1935, 120, 1166—1168).—The antineuritic vals. of both *Torula* are < that of brewer's yeast; the *Torula* with lactose-fermenting power is the more active of the two. R. N. C.

**Yeast growth-promoting substances.** N. NIELSEN (Compt. rend. Trav. Lab. Carlsberg, 1935, 21, No. 7, 151—183).—The effect of growth-promoting substances (I) (bios) on yeast can be shown by the increase in dry wt. of cultures. The heavier is the inoculation the less is the relative increase in growth. (I) can be quantitatively extracted from yeast with boiling  $H_2O$ . The (I) content of yeast cultures is determined by the (I) content of the culture medium. Yeast must contain more than a certain min. amount of (I) to grow on a (I)-free culture medium. Most of the utilised (I) undergoes no great chemical change, as it can be extracted again, but a certain proportion is so transformed that it cannot be extracted. A. H. R.

**Buffered and low oxygen content physiological salt solutions.** M. RANDALL and T. C. DOODY (Biol. Bull., 1935, 68, 258—262).— $Mn(OH)_2$  effectively removes  $O_2$  and buffers solutions from  $p_H$  7.0 to 9.0. Its use is convenient in the culture of protozoa.

CH. ABS. (p)

**Nature of crystals found in amoeba.** R. H. LUCE and A. W. POHL (Science, 1935, 82, 595—596).—The most prominent cryst. inclusions have  $n$  1.668, m.p. approx. 290°; they probably consist of Ca chlorophosphate. L. S. T.

**Ultra-violet irradiated amoebæ.** W. A. BLACK (Science, 1935, 82, 495—497).—*A. proteus* is negatively phototropic towards ultra-violet light. Irradiation appears to stop the digestion of food. L. S. T.

**Infection with *Trypanosoma equiperdum*.** D. PERLA (Arch. Path., 1935, 19, 505—523).—Infected but surviving rats acquired a secondary hæmolytic anæmia, and showed increased [Fe], without change in [Cu], in livers. [Fe] and [Cu] in the spleen declined. CH. ABS. (p)

**Action of certain derivatives of copper on *Treponema cuniculi* and *Trypanosoma brucei*.** R. SAZERAC and N. LARTHE (Compt. rend. Soc. Biol., 1935, 120, 1179—1181).—*T. cuniculi* lesions in the rabbit are cured by injections of  $\text{Na}_2\text{Cu}(\text{S}_2\text{O}_4)_2$ , but in the case of CuO they recur. *T. brucei* infection in the rat is reduced temporarily by  $\text{Cu}_2\text{O}$ , electrocuprol, or 1%  $\text{CuSO}_4$ . R. N. C.

**Changes in the nucleus of *Euglena gracilis*, Ehrbg., in chronic arsenical poisoning.** S. B. RYBINSKY and L. M. ZRYKINA (Arch. Protistenk., 1935, 85, 334—340).—Chronic  $\text{As}_2\text{O}_3$  poisoning results in an increase in the thymonucleic acid of the nucleus and changes in morphological characteristics. A. G. P.

**Relation of hydrogen-ion concentration to growth of *Chilomonas* and *Chlorogonium*.** J. B. LOEFFER (Arch. Protistenk., 1935, 85, 209—223).—Total growth ranges of  $p_{\text{H}}$  and optimum zones are determined for *Chilomonas paramecium*, *Chlorogonium euchlorum*, and *C. elongatum*. NaOAc prevents growth of *Chlorogonium* below  $p_{\text{H}}$  5.4 and of *Chilomonas* below 8.5. A. G. P.

**Influence of heat and storage on electrophoretic migration velocities of various micro-organisms.** K. P. DOZOIS and F. HATCHEL (J. Bact., 1935, 30, 473—477).—Migration velocities increased with rising temp. > 60°. A. G. P.

**Precision photometer for study of bacteria and other micro-organisms.** H. MESTRE (J. Bact., 1935, 30, 335—358).—A "densitometer" used in conjunction with a photo-electric cell is described. A. G. P.

**Growth and survival of micro-organisms at sub-freezing temperatures.** H. F. SMART (Science, 1935, 82, 525).—Many species of bacteria, yeasts, and moulds are able to survive in frozen fruit kept at  $-9.4^\circ$  for 3 years; some of these showed slow growth at  $-8.9^\circ$  in fresh cultures. L. S. T.

**Carbohydrate metabolism of *Aspergillus niger* is a function of the nitrogen source of the nutrient medium.** R. BONNET and J. JACQUOT (Compt. rend., 1935, 201, 1213—1215; cf. A., 1935, 1027).—*A. niger* produces citric (I) and oxalic acid (II) when N is supplied as peptone or  $\text{NH}_2$ -acids. The wt. of mycelium and its (I) content remained practically const. during 4—20 days, but accumulation of (II)

increased progressively. In  $\text{NO}_3'$  media (I) and (II) are produced from all sugars examined, except lactose. In no case was (II) formed in  $\text{NH}_4$  media.

A. G. P.

**Assimilation of oxalic acid by *Aspergillus niger*.** D. BACH and J. FOURNIER (Compt. rend., 1935, 201, 982—984).—5-day-old cultures of this organism consume  $\text{H}_2\text{C}_2\text{O}_4$ ; the amount diminishes with increasing  $p_{\text{H}}$ , and is practically zero at  $p_{\text{H}} > 5.8$ . The acid ion as well as the neutral mol. appears to be utilised. F. A. A.

**Proteolytic enzymes of *Aspergillus niger*.** H. OTANI (Acta Schol. Med. Kioto, 1935, 17, 317—322).—Aq. or glycerol extracts of *A. niger* exhibit digestive properties typical of pepsin, trypsin, and erepsin. Optimum digestion of fibrin occurs at  $p_{\text{H}}$  7.1 or 2.0. CH. ABS. (p)

**Mould enzymes splitting nucleic acid.** H. OTANI (Acta Schol. Med. Kioto, 1935, 17, 323—329).—Glycerol extracts of a no. of species of moulds hydrolysed nucleic acid. Optimum  $p_{\text{H}}$  vals. were between 4.2 and 6.2. CH. ABS. (p)

**Action of mould enzymes on benzene derivatives of amino-acids and dipeptides.** H. OTANI (Acta Schol. Med. Kioto, 1935, 17, 330—333).—Mould enzymes readily decomposed benzoyl-*dl*-leucylglycine. In general hippuric acid was more strongly attacked than benzoyldiglycine. Benzoyl- and benzylglycyl-*dl*-phenylalanine are not attacked. CH. ABS. (p)

**Nutrient solution purification for removal of heavy metals in deficiency investigations with *Aspergillus niger*.** R. A. STEINBERG (J. Agric. Res., 1935, 51, 413—424).—The solution is treated with  $\text{CaCO}_3$  and filtered while hot. Supplementary use of C is unnecessary and lowers experimental precision. Extraction of spores of *A. niger* with aq.  $\text{KHCO}_3$  partly removes Fe, Cu, and Mn. Subsequent growth of treated spores leads to accentuated deficiency effects in respect of these metals.

**Pharmacodynamic action of zinc in general metabolism.** O. KAUFFMAN-COSLA and R. BRULL (Bull. Soc. Chim. biol., 1935, 17, 1828—1835).—The absence of Zn from cultures of *Aspergillus niger* leads to a decrease in the synthesis of carbohydrates, lipins, and protein. A. L.

**Mould tissue. X. Phospholipins of *Aspergillus sydowi*.** D. W. WOOLLEY, F. M. STRONG, W. H. PETERSON, and E. A. PRILL (J. Amer. Chem. Soc., 1935, 57, 2589—2591; cf. A., 1934, 697).—The phospholipins (0.4—0.7% of mycelium), purified by repeated pptn. from  $\text{Et}_2\text{O}$ -solution with COMe., consist of a mixture of lecithin and kephalin. Hydrolysis (5%  $\text{H}_2\text{SO}_4$ ) gives glycerophosphoric acid, choline, cholamine [*picrolonate*, m.p. 222—226° (decomp.)], oleic acid, and (probably) traces of palmitic, stearic, and a more unsaturated acid. H. B.

**Dissimilation of glucose by heterofermentative lactic acid bacteria.** M. E. NELSON and C. H. WERKMAN (J. Bact., 1935, 30, 547—557).—The end-products of fermentation of glucose by three heterofermentative species were lactic acid,  $\text{AcOH}$ ,  $\text{CO}_2$ ,

EtOH, and glycerol. The amount of  $\text{CO}_2$  produced was equiv. to the EtOH+AcOH (mols.), and that of glycerol to twice the AcOH (mols.). A tentative scheme representing these changes is presented.

A. G. P.

**Utilisation of amino-acids as common sources of carbon and nitrogen by soil bacteria: organisms decomposing betaine and valine.** H. HEIGENER (Zentr. Bakt. Par., 1935, II, 93, 81—113).—As simultaneous sources of N and C, valine (I), betaine (II), and glycine were but poorly utilised by soil bacteria; leucine, phenylalanine, alanine, and asparagine were rather more effective. Glutamic and aspartic acid were very generally utilised. Organisms decomp. (I) and (II) were isolated and described and their significance in humus formation is discussed.

A. G. P.

**Relation of oxidation-reduction potential to growth of an aerobic micro-organism.** W. B. WOOD, jun., M. L. WOOD, and I. L. BALDWIN (J. Bact., 1935, 30, 593—602).—Reversible oxidation-reduction indicators positive to, and including, methylene-blue when in oxidised forms inhibit the growth of *B. megatherium*. Indicators negative to this do not inhibit. Substances which are inhibitory in the oxidised form are not bacteriostatic when reduced. Bacteriostatic compounds affect growth only in the lag phase. Addition of inorg. reducing agents to broth renders it more favourable to the growth of the organism.

A. G. P.

**Effect of some alkaloids on soil micro-organisms: nitrogen fixers. I. Effect on *B. radicola*.** G. MEZZADROLI and L. SGARZI (Giorn. Biol. Appl. Ind. Chim., 1934, 4, 162—174; Chem. Zentr., 1935, i, 3679).—Development is stimulated by caffeine, quinine, and strychnine, the effect in nutrient solution being > that in soil mixture. Glucose can serve as a source of carbohydrate.

R. N. C.

(A) Action of radiation in the extreme ultra-violet on *Bacillus subtilis* spores. (B) Inhibition of growth of *B. subtilis* by ultra-violet-irradiated carbohydrates. I. H. BLANK and W. ARNOLD (J. Biol. Chem., 1935, 110, 503—506, 507—511).—(A) Radiation region —140 m $\mu$  has a marked germicidal action.

(B) Radiations of 235.7 m $\mu$  modify agar in a manner which prevents the growth on it of *B. subtilis*. A non-thermostable inhibitory agent, diffusible through agar, is formed. A similar inhibition is observed by irradiation of carbohydrate solutions used in the prep. of media.

A. G. P.

**decomposition of chitin.** H. BUCHE (Zentr. Bakt. Par., 1935, II, 93, 12—24).—Organisms decomp. chitin are isolated from soil and other sources.

A. G. P.

**Urea-decomposing microflora of soils. I.** See B., 1936, 114.

**Mannitol-forming bacteria isolated from potatoes (*Ipomoea edulis*, Makino), and Diospyros kaki.** Y. IWASAKI (Bull. Japan. Soc. Japan, 1935, 11, 159—164, 164). Both strains produce mannitol from

fructose, but not from glucose, mannose, or galactose. Morphological characteristics are given. F. O. H.

**Anaerobic bacteria capable of fermenting waste sulphite liquor.** A. M. PARTANSKY and B. S. HENRY (J. Bact., 1935, 30, 559—571).—Five new species of *Clostridium* are described, and their biochemical activities are recorded.

A. G. P.

**Production of *d*-lactic acid and of butyric acid.**—See B., 1936, 167.

**Amylase of *Clostridium acetobutylicum*.** W. W. JOHNSTON and A. M. WYNNE (J. Bact., 1935, 30, 491—501).—The amylase shows optimum activity at  $p_{\text{H}}$  4.8—5.05. NaOAc retards its action *in vitro*, but when added to the culture media increases the amount of amylase present in the nutrient at the end of the fermentation.  $\text{PO}_4'''$  and  $\text{Cl}'$  also retard starch hydrolysis at  $p_{\text{H}}$  4.95. Temp. effects are examined.

A. G. P.

**Effect of synthetic surface-active materials on bacterial growth. I. Effect of sodium di-sec-butyl-naphthalenesulphonate on growth of *Mycobacterium smegmatis*.** J. KATZ and A. LIPSITZ (J. Bact., 1935, 30, 419—422).—In concns. of 1:10,000 the salt inhibits growth. In small proportions (to 1:50,000) involution forms occur frequently. No synergistic action was apparent between the salt and neutral acriflavine.

A. G. P.

**Existence in *B. tumefaciens* of an endotoxin capable of causing the formation of tumours in plants.** A. BOIVIN, M. MARBE, I. MESROBEANU, and P. JUSTER (Compt. rend., 1935, 201, 984—986).— $\text{CCl}_3\cdot\text{CO}_2\text{H}$  extracts a "complete" antigen (I) from *B. tumefaciens* (II), corresponding with 3% of the dry wt. of the bacteria. (I) is a solid, aq. solutions of which are not dialysable. In dil. AcOH at 100° it yields fatty acids and a slowly dialysable polysaccharide (III) ("residual antigen"). Both (I) and (III) are pptd. specifically by serum from rabbits injected with (II). (I) is toxic to mice, whilst (II) is non-toxic. (I) produces tumours in *Helianthus annuus* stems similar to those produced by living (II).

F. A. A.

**Bactericidal action of organic acids towards Bang's bacillus.** E. ZIMMERMAN (Zentr. Bakt. Par., 1935, I, 215—221).—Lactic, tartaric, citric, and (especially) formic acid have marked toxic action on the bacillus. Lethal dosages are determined. Possible chemotherapeutic uses of org. acids are discussed.

A. G. P.

**Presence of hæmolysins in young cultures of cholera vibrios.** W. DOORENBOS (Compt. rend. Soc. Biol., 1936, 121, 128—129).

R. N. C.

**Cultural requirements of bacteria. VI. Diphtheria bacillus.** J. H. MUELLER. VII. Amino-acid requirements for the Park-Williams No. 8 strain of diphtheria. J. H. MUELLER and I. KAPNICK (J. Bact., 1935, 30, 513—524, 525—534). VI. Animal tissue extracts contain substances essential to the growth of the organism. Considerable amounts of the active substance occur in the 95% EtOH filtrate of aq. liver extract (beef), and may be adsorbed on C and eluted with acidified EtOH. The

filtrate from such C adsorptions also contains growth-stimulating materials, including K and Mg.

VII. This strain grows freely on media containing only *l*-cystine, *d*-glutamic acid, *dl*-valine, *dl*-leucine, *dl*-methionine, glycerol, inorg. salts, and liver "elute." The prep. of the latter is described. A. G. P.

Electrophoretic phenomena of bacteria. II. Electrophoretic velocities of virulent and non-virulent *C. diphtheriae*. III. Electrophoretic velocity in relation to growth, senescence, and death. C. W. BUGGS and R. G. GREEN (J. Bact., 1935, 30, 447—451, 453—463).—II. Although no strict line of demarcation was apparent, the average velocity of all non-toxicogenic strains is 18.8% > that of all toxicogenic strains.

III. The velocity of cultures was approx. const. from 6 hr. to 10 days, and showed variable changes after killing by heat, but not after treatment with  $\text{PhOH}$ ,  $\text{CH}_2\text{O}$ , or  $\text{HgCl}_2$ . Extraction of cultures with hot 70% EtOH lowered the velocities approx. to those of cells killed in  $\text{PO}_4^{'''}$  buffer solution.

A. G. P.

Metabolic activity of various colon group organisms at different phases of the culture cycle. G. MOONEY and C. E. A. WINSLOW (J. Bact., 1935, 30, 427—440).—The presence of a fermentable sugar (glucose) stimulates multiplication of *E. coli* and *Salmonella gallinarum* in aerated media, but tends to inhibit that of *S. pullorum*. Production of  $\text{CO}_2$  per cell per hr. by organisms in the same period of culture cycle is independent of species and culture medium. Metabolic rates vary considerably with the phase of the cycle. The period of physiological youth in cultures is characterised by relatively larger cells and by greater metabolic activity per unit of living matter concerned.

A. G. P.

*Escherichia coli* and three of its rough variants. E. H. RENNEBAUM (J. Bact., 1935, 30, 625—638).—As energy sources AcOH, lactic, and malic acids are more readily utilised by the parent cell, whilst tartaric, citric, and salicylic acids are preferentially utilised by one or more of the variants. A typical rough variant has less vigorous enzymes than the parent, in respect of glucose decomp. Injection of the normal strain into the ear vein of rabbits causes a sudden increase in blood-sugar and death in a few hr. Variants have no appreciable action. The fatal action of the normal form is probably due to a sol. exo-toxin which increases the permeability of lung capillaries.

A. G. P.

"Complete" somatic antigen contained in some *B. coli*. A. BOIVIN, L. MESROBEANU, G. MAGHERU, and A. MAGHERU (Compt. rend. Soc. Biol., 1935, 120, 1276—1279).—Eight strains of *B. coli* examined fall into six serological types. The "complete" antigens contain 38—48.4% of sugar and 9.9—20.7% of fatty acid (liberated by acid hydrolysis); the chemical composition is not const. for strains of the same type.

R. N. C.

"Residual" antigen of *B. coli*. G. MAGHERU, A. MAGHERU, A. BOIVIN, and L. MESROBEANU (Compt. rend. Soc. Biol., 1935, 120, 1279—1282). R. N. C.

Importance of the electric charge in certain aspects of immunity. H. C. BROWN and J. C. BROOM (Trans. Roy. Soc. Trop. Med. Hyg., 1935, 28, 357—376).—*Leptospira* are killed by colloidal Cu when suspended in immune but not when in normal serum. Victoria-blue is toxic in both sera. If the charge on red cells is diminished, a hæmolytic serum becomes inactive. CH. ABS. (p)

Violet agar reaction as a differential characteristic of the *Micrococcus catarrhalis* group. G. H. CHAPMAN (Stain Tech., 1936, 11, 25—26).—The crystal-violet-agar reaction is useful in the study of different strains of this group. P. G. M.

Cultural characteristics of *Pasteurella tularensis*. C. M. DOWNS and G. C. BOND (J. Bact., 1935, 30, 485—490). A. G. P.

Effects of quinine derivatives in experimental *Pneumococcus* studies. W. W. G. MACLACHLAN, H. H. PERMAR, J. M. JOHNSTON, and J. R. KENNEY (Amer. J. Med. Sci., 1934, 188, 699—705).—Toxicity of ethylapoquinine varies considerably, but decreased toxicity does not diminish its protective power. Hydroxyethylapoquinine is less toxic but has greater antipneumococcal power. Hydroxyethylhydrocyprene is the least toxic, and its protective action is < that of other derivatives. CH. ABS. (p)

Anaerobic surface cultures. II. Gaseous products of metabolism of organisms (yeast, *Staphylococcus aureus*, *B. coli*, *B. prodigiosum*): aldehyde content and bactericidal action at a distance. W. BACHMANN and OGAIT (Zentr. Bakt. Par., 1935, I, 134, 281—288).—The inhibitory action (at a distance) of certain yeasts etc. on aerobic and anaerobic bacteria depends on the production of appreciable amounts of MeCHO. A. G. P.

Denaturation of staphylococcal proteins. A. P. KRUEGER and V. C. NICHOLS (J. Bact., 1935, 30, 401—409).—Antigens separated by ultrafiltration contain < 10% of the total bacterial protein in the denatured form. On heating, the native proteins are denatured, become insol. at the isoelectric point, and show a considerable decrease in -SH. The denaturation process obeys the law of mass action. The facts are considered in relation to the prep. of vaccines and the preservation of active antigens.

A. G. P.

Organism of European foul-brood of bees. H. L. A. TARR (Nature, 1936, 137, 151—152).—Photomicrographs of two kinds of *Streptococcus apis*, which differ only in that one rapidly liquefies gelatin and coagulates and peptonises the casein of milk, are reproduced. L. S. T.

Donators and acceptors of hydrogen for *Streptococcus haemolyticus*. D. BACH (Compt. rend. Soc. Biol., 1936, 121, 215—217).—Fructose, glucose, mannose, xylose, galactose, lactose, sucrose, maltose, arabinose, glycerol,  $\text{CH}_3\text{CH}_2\text{OH}$ , EtOH, MeOH, Bu'OH, lactate, cysteine, fumarate, and pyruvate are active H donators; NaBrO<sub>3</sub> and NaIO<sub>3</sub> are the only active H acceptors. R. N. C.

Lipins of tubercle bacilli. XLI, XLII.—See this vol., 311, 314.

Comparison of antigenic properties of defatted tubercle bacilli and their derived proteins. C. H. BOISSEVAIN (Amer. Rev. Tuberc., 1935, 31, 547—552).—The  $H_2O$ -sol. proteins from ground or hydrolysed bacilli or from filtered culture media all have the same tuberculin activity. Guinea-pigs cannot be rendered hypersensitive to 1% tuberculoprotein by injection of 10—100 mg. of any  $H_2O$ -sol. protein or peptone derived from the bacillus. CH. ABS. (p)

Preparation of purified tuberculin. A. BOQUET and G. SANDOR (Compt. rend. Soc. Biol., 1936, 121, 99—100).—Tubercle bacilli filtrate is pptd. with phosphotungstic acid and  $H_2SO_4$ . The ppt. is collected by centrifuge, washed with 0.2N- $H_2SO_4$ , and eluted with  $Ba(OH)_2$  solution; the residue is washed twice with  $H_2O$  and the eluate and washings are combined and filtered. The stable filtrate contains tuberculin. R. N. C.

Cultural characters of *Trichomonas (Trichomonastix) colubrorum*. R. CAILLEAU (Compt. rend. Soc. Biol., 1936, 121, 108—110).—*T. colubrorum* ferments glucose, galactose, fructose, maltose, sucrose, raffinose, and lactose with production of acid. Horse serum, but not rabbit serum, can replace whole blood or organs as nutrient. R. N. C.

Nitrogen distribution in the protein of mouse typhoid bacillus. H. OTANI (Acta Schol. Med. Kioto, 1935, 17, 334—337).—Data are given for the dry defatted bacilli and for the fraction pptd. from a conc.  $H_2SO_4$  extract on dilution to 5%. CH. ABS. (p)

Variation of the hæmolytic power of the El Tor vibrio. W. DOORENBOS (Compt. rend. Soc. Biol., 1936, 121, 130—132). R. N. C.

Microbiological basis of chemotherapeutic action. III. Fixation of therapeutically administered gold compounds by various recurrent spirochætes. N. VON JANCsó and E. NOVAK (Zentr. Bakt. Par., 1935, I, 134, 159—169).—Fixation of Au by *Sp. obermeiri* is reversible. Washing with serum removes the Au. *Sp. usbekistanica* does not absorb Au to any appreciable extent. A unimol. surface fixation by this organism is postulated. A. G. P.

Bacteriostatic and bactericidal studies of dyes and allied compounds. S. A. PETROFF and W. S. GUMP (J. Lab. Clin. Med., 1935, 20, 689—698).—zine, oxazine, thiazine, and basic CHPh<sub>3</sub> dyes (I), anti-quinoline derivatives (II), and some alkaloids have bactericidal and bacteriostatic effects on Gram-positive organisms. The order of activity for Gram-negative organisms was (II) > (I) > acridine dyes. CH. ABS. (p)

Study of the relations between bacteria, ultra-ruses, bacteriophages, toxins, and enzymes, by means of the action of gonacrine. C. LEVADITI, ER, and G. HORNUS (Bull. Acad. med., 1934, 112, 573—586).—Gonacrine rapidly suppresses the virulence, and sp. activity of bacteria, bacteriophages, and ultraviruses (except that of poliomyelitis), but does not affect toxins or enzymes. R. N. C.

Production of a neurotropic strain of Rift Valley fever virus. R. D. MACKENZIE and G. M. FINDLAY (Lancet, 1936, 230, 140—141). L. S. T.

Action of sodium ricinoleate on rabies virus. H. VIOLLE and J. LIVON (Compt. rend. Soc. Biol., 1936, 121, 100—102).—Na ricinoleate injected with rabies virus in rabbits prevents the onset of rabies. R. N. C.

Cultivation of the virus of St. Louis encephalitis. J. T. SYVERTON and G. P. BERRY (Science, 1935, 82, 597). L. S. T.

Apparatus for determining the fermentative properties of aerobic and anaerobic micro-organisms. A. P. STRUYK (Chem. Weekblad, 1936, 33, 44—45). S. C.

Hormonal equilibrium and hormonal derangement in the interferometric picture of the serum. A. SCHITTENHELM, F. CHROMETZKA, and W. SPIEKER (Z. ges. exp. Med., 1935, 95, 149—167; Chem. Zentr., 1935, i, 3431). R. N. C.

Gaseous exchange after injection of adrenaline in cocks and owls. A. PAGANO (Boll. Soc. ital. Biol. sperim., 1935, 10, 540—542).—Gaseous exchange, as in pigeons, is scarcely affected. R. N. C.

Adrenal cortex and carbohydrate metabolism. S. THADDEA (Z. ges. exp. Med., 1935, 95, 600—626; Chem. Zentr., 1935, i, 3299).—Adrenal cortex hormone injected into guinea-pigs causes increase of blood-sugar and of liver- and muscle-glycogen; it counteracts the action of insulin. G. H. F.

Modifications of the hypertensive action of adrenaline by certain colloidal products. D. BROWN and A. BEAUNE (Compt. rend. Soc. Biol., 1935, 120, 1202—1204).—The action of adrenaline in the dog is reduced by colloidal lipins, and by certain colloidal metals and proteins. R. N. C.

Physiology of the autonomous nervous system. VI. Action of adrenaline on the blood-calcium of the dog with parathyroid insufficiency. F. MATHIEU and Z. M. BACQ. VII. Phosphagen in the muscle of the sympathectomised cat. W. L. DULIERE, Z. M. BACQ, and L. BROUHA (Arch. int. Physiol., 1934, 38, 160—163, 164—171; Chem. Zentr., 1934, ii, 3401).—VI. Serum-Ca falls 10—15 min. after intravenous injection of adrenaline, which therefore has only a secondary rôle in Ca regulation.

VII. P in the muscles affected is increased some time after sympathectomy, owing to the slackening of the process of resynthesis. After 3—5 months P metabolism in the resting state is scarcely affected, whilst in the muscle a compensating or adapting process has taken place. R. N. C.

Action of adrenaline and potassium on the phosphagen of muscle poisoned with iodoacetic acid. J. WAJZER, R. LIPPMANN, and A. MARNAY (Compt. rend. Soc. Biol., 1936, 121, 142—144).—Adrenaline scarcely affects phosphagen (I) in the isolated  $CH_2I-CO_2H$ -poisoned frog's muscle in anaerobiosis, no resynthesis occurring even when (I) is almost absent from the muscle. Excess of K<sup>+</sup> causes a breakdown of (I). R. N. C.

**Influence of rapidity of intravenous injection of adrenaline on hyperglycæmic action.** Y. SUGANUMA (*Folia Pharmacol. Japon.*, 1935, 19, 412—416).—The longer was the time of injection the stronger was the hyperglycæmic response (max. at 10—30 min.). CH. ABS. (p)

**Decomposition of adrenaline in tissues.** H. BLASCHKO and H. SCHLOSSMANN (*Nature*, 1936, 137, 110).—Rat-liver tissue accelerates the loss of adrenaline (I) activity in presence of O<sub>2</sub>. The O<sub>2</sub> uptake of liver tissue is not markedly influenced by (I), but that of liver extracts is increased when (I) is added. In presence of tissue extracts activity is approx. halved after the uptake of one O and practically abolished after that of 2 O per mol. of (I). L. S. T.

**Significance of the vegetative nervous system on the regulation of blood-sugar.** E. FYLLA (*Minerva med.*, 1935, I, 489—494).—Insulin (I) injection with adrenaline is less effective in producing hypoglycæmia than is (I) alone. Simultaneous injection of atropine and ginerin followed by (I) has a greater effect than (I) alone. CH. ABS. (p)

**Action on local glycæmia, *in vivo*, of insulin injected intravenously.** D. OLMER, J. OLMER, J. PAILLAS, and J. VAGUE (*Compt. rend. Soc. Biol.*, 1936, 121, 76—78).—Injection of insulin in a section of a limb that has been ligatured off from the circulation causes a local fall of blood-sugar that varies with the subject. The hypoglycæmic action of insulin probably depends on direct glycæmic and muscular glycolysis, but the hepatic factor is excluded. R. N. C.

**State of functional reactivity of the endocrine pancreatic tissue in normal dogs subjected to prolonged biquotidian injection of insulin.** E. AUBERTIN, A. LACOSTE, and R. SARIC (*Compt. rend. Soc. Biol.*, 1936, 121, 241—244).—The blood-sugar curve after glucose does not exhibit an abnormal rise in animals subjected to prolonged insulin treatment, but the post-hyperglycæmic fall is increased. R. N. C.

**Influence of insulin on the liver-glycogen level of frogs.** E. GEIGER [with H. HALMOS] (*Arch. exp. Path. Pharm.*, 1936, 180, 251—257).—Continuous electrical stimulation of the muscles in summer and spring (but not winter) frogs diminishes the liver-glycogen (I). Prior administration of insulin (II) inhibits this change. Administration of glucose causes production of (I) in all seasons, but the increase in (I) of summer frogs disappears after a few days unless (II) is injected. Hence the seasonal variation in (I) is due to deprivation of (II), which inhibits glycogenolysis but does not influence (I) formation. F. O. H.

**Direct action of glucose on secretion of insulin by the pancreas.** V. G. FOGLIA and R. FERNANDEZ (*Compt. rend. Soc. Biol.*, 1936, 121, 355—358).—Injection of glucose in a dog with a pancreatic graft on the neck causes an increase of insulin secretion in the graft, independent of extrinsic innervation. R. N. C.

**Effect of repeated injections of insulin on the histological state of the endocrine pancreatic tissue and its insulin content in the normal dog.**

A. LACOSTE, E. AUBERTIN, and R. SARIC (*Compt. rend. Soc. Biol.*, 1936, 121, 239—241).—The no. of islets of Langerhans and the insulin content are increased. R. N. C.

**Modifications of the cardiovascular action of acetylcholine by insulin.** D. BROWN and A. BEAUNE (*Compt. rend. Soc. Biol.*, 1935, 120, 1205—1208).—The action is reinforced by insulin. R. N. C.

**Effect on local glycæmia, *in vivo*, of parathyroid hormone injected intravenously.** J. OLMER, J. PAILLAS, and B. SICNAST (*Compt. rend. Soc. Biol.*, 1936, 121, 78—80).—Intravenous injection of parathormone (I) in a section of a limb that has been ligatured off from the circulation does not affect local blood-sugar; the action of (I) is therefore not due to direct glycolytic influence exercised by muscle or blood. R. N. C.

**Effect of parathyroid extract on blood coagulation.** R. BONNYNS (*Arch. Int. Physiol.*, 1934, 40, 189—208).—Parathyroid extract (I) does not affect coagulation of re-calcified oxalated blood *in vitro*. The time of coagulation of such blood of rabbits is reduced by intravenous injection of (I), reaching its min. 45 min. after injection, and returning to normal in 3 hr. The action takes place principally in the second phase of (I) action. Plasma-scrozyme is increased, and also, very slightly, the fibrinogen and platelet contents of the blood, the  $p_H$  and alkaline reserve being unaffected. R. N. C.

**Action of hormones on the secretion of digestive enzymes. Effect of (I) thyroid, (II) parathyroidectomy, (III) insulin, on the composition of gastric juice.** R. FERRARI (*Boll. Soc. ital. Biol. sperim.*, 1934, 9, 1320—1322, 1323—1325, 1325—1328).—I. Thyroid preps. fed to dogs increase the enzyme content of the gastric juice; thyroidectomy reduces it, whilst subsequent administration of thyroid preps. restores it to the normal val. Total acidity and free HCl are unaffected.

II. Parathyroidectomy increases the enzyme content and free HCl, but does not affect total acidity.

III. Insulin increases the enzyme content, total acidity, and free HCl as the blood-sugar falls, and vice versa; the rate of secretion is also increased. Glucose increases enzyme content and free HCl slightly, but does not affect total acidity. R. N. C.

**Rôle of cholesterol in thyroid-ovarian antagonism: ovarian and adrenal cholesterol in thyroidectomised and thyroxine-treated animals.** C. I. PARHON, C. PARHON-STEFANESCU, and I. ORNSTEIN (*Compt. rend. Soc. Biol.*, 1936, 121, 187—189).—Thyroidectomy in rabbits and guinea-pigs causes an increase in ovarian cholesterol (I), which is slightly further increased in rabbits and decreased in guinea-pigs by administration of excess of thyroxine (II). Adrenal (I) is decreased in guinea-pigs and increased in rabbits by both thyroidectomy and excess of (II). (I) is apparently concerned in thyroid-ovarian antagonism. R. N. C.

**Influence of thyroxine on the oxygen consumption of surviving tissue.** W. HAARMANN (*Arch. exp. Path. Pharm.*, 1936, 180, 167—182).—

The  $O_2$  consumption of surviving muscle or liver tissue is increased by addition of  $10^{-17}$ – $10^{-9}\%$  (max.  $10^{-12}$ – $10^{-14}\%$ ) of thyroxine: higher concns. have an inhibitory action. F. O. H.

**Influence of thyroxine on tissue respiration.** A. REUTER (Z. ges. exp. Med., 1935, 95, 214–216; Chem. Zentr., 1935, i, 3300).—Thyroxine caused a rise in  $O_2$  consumption of isolated organs of rat and cat (Warburg's method) of 20–35%; the effect vanished after 1–2 hr. Results on isolated organs may not be comparable with those on living organisms. G. H. F.

**Pathogenesis of the histological alterations of the myocardium with excessive administration of synthetic thyroxine.** C. MANZINI and E. COSTANTINI (Boll. Soc. ital. Biol. sperim., 1935, 10, 597–600). R. N. C.

**Mode of toxic action of excessive administration of thyroxine on the liver.** C. MANZINI and E. COSTANTINI (Boll. Soc. ital. Biol. sperim., 1935, 10, 594–597). R. N. C.

**Histological lesions of the liver with excessive administration of thyroxine.** C. MANZINI and E. COSTANTINI (Boll. Soc. ital. Biol. sperim., 1935, 10, 591–594). R. N. C.

**Influencing of the thyroxine-catechin balance of different types of blood by a growth-promoting principle.** H. EUFINGER and J. B. GOTTLIEB (Klin. Woch., 1934, 13, 1204–1205; Chem. Zentr., 1934, ii, 3396).—The effect of thyroxine (I) on *Rana temporaria* when added to the aquarium- $H_2O$  is restricted by addition of umbilical, retroplacental, or pubertal blood, which contain an inhibitory and growth-promoting substance. Lactic and uric acids increase the effect of (I), probably through shifting of  $pH$ . R. N. C.

**Occurrence of thyrotropic hormone in the central nervous system and cerebrospinal fluid.** A. SCHITTENHELM and B. EISLER (Z. ges. exp. Med., 1935, 95, 121–123; Chem. Zentr., 1935, i, 3434).—Thyrotropic hormone occurs in the mid-brain and cerebrospinal fluid of the cat. The mid-brain contains  
o 1/3 of the pituitary content. R. N. C.

**Transmission of thyrotropic hormone through the placenta and milk.** A. SCHITTENHELM and EISLER (Z. ges. exp. Med., 1935, 95, 124–125; Chem. Zentr., 1935, i, 3298).—Thyrotropic hormone administered to guinea-pigs, when pregnant or when nursing young, produced no change in the thyroids of the young. G. H. F.

**Anti-thyrotropic substance in blood and carbohydrate metabolism of the liver.** A. LOESER (Z. ges. exp. Med., 1936, 180, 325–331).—The principle (I) antagonistic to the anterior pituitary thyrotropic hormone (A., 1935, 1543) inhibits the characteristic symptoms of hyperthyroidism. The hepatic carbohydrate metabolism indicates that changes (e.g., glycogenolysis) due to thyroxine are independent of the thyroid gland are not influenced. The relation of (I) to thyroid activity is dis

**Effect of pituitary on protein metabolism. I. Pituitary preparations. II. Thyroid preparations. III. Pancreatic preparations. IV. Adrenal preparation. V. Ovarian preparations.** Y. TOKIZAKI (Sei-i-Kwai Med. J., 1934, 53, No. 9, 212–242, No. 10, 105–117, 118–129, 130–139, 140–148).—I. Hypophysectomy decreases protein (I) metabolism and only the anterior pituitary prep. can accelerate it.

II. Injection of thyroxine accelerates (I) metabolism in normal and hypophysectomised dogs, the action being less in the latter.

III. Injection of insulin into normal animals increases all N fractions in urine, and the total, non-protein-,  $NH_3$ -, and creatinine-N in blood. Blood-urea, -uric acid, -creatine, and  $-NH_2$ -acid decline. With hypophysectomised dogs all urinary N fractions increase, blood-uric acid increases, and all other N fractions together with  $HIO_3$  decrease.

IV. Adrenaline increases (I) metabolism in normal and hypophysectomised animals.

V. Ovarian prep. (oophormin) increases (I) metabolism in normal > in hypophysectomised dogs.

CH. ABS. (p)

**Influence of pituitary preparations on non-protein-nitrogen and urea in blood, and iodic acid in serum, of normal and hypophysectomised dogs.** Y. TOKIZAKI (Sei-i-Kwai Med. J., 1934, 53, No. 10, 149–158).—Pituitrin and pituglandol increased, but hypophorin decreased, the non-protein-N and urea in blood of normal and hypophysectomised dogs.  $HIO_3$  in serum increased in all cases.

CH. ABS. (p)

**Difference of response of the pituitary glands of male and female albino rats treated with the growth hormone.** H. S. RUBINSTEIN (Anat. Rec., 1934, 61, 131–140). R. N. C.

**Significance of the pituitary in kidney disease.** H. MARX (Klin. Woch., 1935, 14, 367–372; Chem. Zentr., 1935, i, 3153). G. H. F.

**Stability of anterior pituitary extract in aqueous solution.** I. W. ROWLANDS (Quart. J. Pharm., 1935, 8, 642–645).—Aq. extracts of anterior pituitary preps. lost about 50% of their gonadotropic activity in 9 days at room temp. and in about 1 year at 0–2°. W. O. K.

**Migraine as a pituitary disease and its treatment with ovarian preparations.** I. MUELLER (Med. Klinik, 1935, 31, 448–450).—The anterior pituitary hormone content of the urine of women suffering from migraine is frequently > normal. Progynon exerts a curative effect. R. N. C.

**Adrenaltropic action of the anterior pituitary.** K. J. ANSELMINO, L. HEROLD, and F. HOFFMANN (Klin. Woch., 1934, 13, 1724).—The chrome-pigmentability of the adrenal medulla is almost abolished and vacuole formation increased by injection of anterior pituitary extract in rats or mice. The active principle is sensitive to acids and alkali, but comparatively thermostable; it can be separated from the corticotropic hormone by ultrafiltration through collodion, which retains it. R. N. C.

Influence of hormones of the anterior and posterior lobes of the pituitary, the thyroid, and the adrenals on the spontaneous creatinuria of endocrine disturbances. A. SCHITTENHELM and F. BUHLER (Z. ges. exp. Med., 1935, 95, 206—213; Chem. Zentr., 1935, i, 3435).—Spontaneous creatinuria in males with gonadal insufficiency is abolished by prolant and orasthin, but not by prahormone. Thyrotropic hormone and thyroxine induce creatinuria in myxœdema. Spontaneous creatinuria in Addison's disease is abolished by small doses of cortical preps.; its appearance is due to increased breakdown of phosphagen in the muscles. R. N. C.

Glyco-chloro-proteinæmic curve in normal and diabetic individuals after injection of posterior pituitary extract. G. DELL'ACQUA (Boll. Soc. ital. Biol. sperim., 1935, 10, 423—447).—Injection of the extract in normal subjects induces a short rise of blood-sugar (I) followed by a prolonged fall and recovery to normal. Proteins (II) show a fall followed by a recovery to almost normal; NaCl falls without recovering. In diabetics (I) shows a marked rise followed by a fall without recovery. (II) rise rapidly at first, fall to vals. < normal, and then rise slowly to > the first max. NaCl rises irregularly. R. N. C.

Determination of the excretion of prolant by mature and by aged men. H. SAETHRE (Klin. Woch., 1935, 14, 376—378; Chem. Zentr., 1935, i, 3153).—The urinary prolant excretion of healthy men is 25—30 mouse units per litre. In old age there may be some increase. G. H. F.

Prepubertal reversal of the sex difference in the gonadotropic hormone content of the pituitary gland of the rat. H. M. CLARK (Anat. Rec., 1934, 61, 175—192).—The prolant content of the pituitary in the immature female rat is > that in the male; at puberty the male gland is more potent. From 4 to 6 months the sex difference is negligible, whilst at 7 months it is reversed. In the female the content rises sharply at 13—20 days, whilst in the male it increases gradually to a const. level at puberty. R. N. C.

Sex difference in the change of potency of the anterior pituitary following bilateral castration in newborn rats. H. M. CLARK (Anat. Rec., 1934, 61, 193—202).—Prolant in the male pituitary increases on castration; it fluctuates in females. R. N. C.

Is there an antagonism of sex hormones? O. O. FELLNER (Z. ges. exp. Med., 1935, 95, 373—377; Chem. Zentr., 1935, i, 3431—3432).—Hormones are extracted from urine by boiling with CaO and pptn. with  $\text{Na}_2\text{C}_2\text{O}_4$ , the hormones remaining in the filtrate. The masculin (I) content of pregnancy urine is > that of male urine, (I) probably originating from the placenta. The sex hormone antagonism hypothesis is discarded in favour of one of synergism between the hormones and gonads. R. N. C.

Physiology of  $\Delta^5$ -androstenediol. A. BUTENANDT (Naturwiss., 1936, 24, 16).— $\Delta^5$ -Androstenediol in pure condition displays the activities of both testicular and follicular hormones. W. O. K.

Action of the male hormone (androsterone) injected into the chicken embryo: experimental production of intersexuals. E. WOLFF (Compt. rend. Soc. Biol., 1935, 120, 1312—1314).

R. N. C.

Interpretation of the results obtained by injection of synthetic androsterone in the chicken embryo. E. WOLFF (Compt. rend. Soc. Biol., 1935, 120, 1314—1316).

R. N. C.

Influence of sex hormone on the spontaneous creatinuria of endocrine disturbances. A. SCHITTENHELM and F. BUHLER (Z. ges. exp. Med., 1935, 95, 197—205; Chem. Zentr., 1935, i, 3433).—Spontaneous creatinuria in males with gonadal insufficiency is abolished by "proviron," but not if muscle metabolism has been disturbed by degenerative muscle changes. Similar creatinuria in women at the climacteric is abolished by "progynon," but not so uniformly. In certain cases creatinuria is abolished also by the heterosexual hormone.

R. N. C.

Response of immature rats to various gonadotropic substances. R. DEANESLY (Quart. J. Pharm., 1935, 8, 651—668).—Various gonadotropic preps. were administered to male and female immature rats and their resulting actions observed. A method of assay which employs 10 rats with an error of  $\pm 10\%$  is described. W. O. K.

Relative activity of different gonadotropic preparations on œstrous rabbits, pregnant rabbits, and immature rats. I. W. ROWLANDS (Quart. J. Pharm., 1935, 8, 646—650).—Extracts of pituitary gland (cow, horse) and urine of pregnancy have been assayed on œstrous, 15 days- and 25 days-pregnant rabbits, and on immature rats. For ovulation, pregnant rabbits require more of all extracts tested than do œstrous rabbits. Horse pituitary and urine of pregnancy extracts are relatively equally potent when tested on rabbits and rats, but ox pituitary is less potent in rats. W. O. K.

Physiology of the corpus luteum. IX. Inhibition of œstrin by progestin-containing extracts of the corpus luteum. W. M. ALLEN and R. K. MEYER (Anat. Rec., 1935, 61, 427—439).—Progestin inhibits cornification by œstrin and the œstrous smear. R. N. C.

Structure of œstrin in alkaline solution. K. P. BJERGAARD and S. A. SCHOU (Quart. J. Pharm., 1935, 8, 669—673).—In neutral or acid EtOH solution, the max. ultra-violet absorption of œstrin occurs at 282 m $\mu$ , whilst in alkaline solution it is at 295 m $\mu$ . The shift is probably associated with enolisation of the keto-group. W. O. K.

Biological activity of theelol. R. K. MEYER, L. C. MILLER, and G. F. CARTLAND (J. Biol. Chem., 1936, 112, 597—604).—Theelol (I) has little biological activity compared with international standard theelin (II) when determined by the vaginal smear method, but it is 4 times as active when determined by the opening of the vagina of the immature rat. (II) is approx. 90 times as active as (I) when administered in oil and 250 times when injected in aq. 10% EtOH containing 0.5%  $\text{Na}_2\text{CO}_3$ . J. N. A.

**Follicular hormone content of eclamptic blood.** W. BICKENBACH and H. FROMME (Klin. Woch., 1935, 14, 496—497).—The follicular hormone content of the blood of eclamptic women is  $\times$  that of the blood of pregnancy. R. N. C.

**Sexual hormones in domestic animals.** KÜST (Klin. Woch., 1934, 13, 1782—1784).—Pregnancy is diagnosed in mares by the Aschheim-Zondek serum reaction from the sixth week to the fifth month, and later by increased follicular hormone (I) excretion in the urine. (I) excretion is increased in the 23rd week in cows, and after 3½ months in goats; in the sow it reaches max. in the fourth week and at the end of pregnancy. (I) is present in the urine of mature boars. R. N. C.

**Sexual hormones in domestic animals.** S. KOBER (Klin. Woch., 1935, 14, 381).—Excretion of follicular hormone in the urine of the pregnant mare appears before the 110th day, rises to a max. between the 6th and 8th months, and then falls to a trace at the conclusion of pregnancy (cf. preceding abstract). R. N. C.

**Artificial (hormonal) growth of the oviduct in female carp.** K. EHRLHARDT and K. KÜHN (Endokrinol., 1934, 15, 1—14; Chem. Zentr., 1935, i, 3433; cf. A., 1935, 413).—The oestrus hormone (I) is apparently not identical with the oviduct hormone (II); crude (I) affects the oviduct more strongly than the cryst. product, whilst (II), although resembling (I) in solubility, thermostability, and adsorbability on C, is difficult to elute from the adsorbate, and is destroyed by 15% NaOH or by AcOH. R. N. C.

**Embryological interpretation of changes induced by oestrogens in the male reproductive tract.** S. ZUCKERMAN (Lancet, 1936, 230, 135—136). L. S. T.

**Follicular and luteal hormones and their reaction on the anterior lobe of the pituitary.** CLAUERG and W. BREIPOHL (Klin. Woch., 1935, 14, 119—121; Chem. Zentr., 1935, i, 3298). G. H. F.

**Inhibitory effect of follicular hormone on the anterior lobe of the pituitary gland.** B. ZONDEK (Lancet, 1936, 230, 10—12). L. S. T.

**Biological determination of corpus luteum acts.** R. COURRIER (Compt. rend. Soc. Biol., 1935, 120, 1263—1266). R. N. C.

**Antigonadotropic hormone in the pineal gland, and organs.** P. ENGEL (Z. ges. exp. Med., 1935, 95, 441—457; Chem. Zentr., 1935, i, 3300).—Antigonadotropic hormone (I) of pineal gland is standardised by injecting into immature female rats simultaneously with standardised gonadotropic hormone anterior pituitary (II). The amount of (I) required to neutralise the effect of a rat unit of (II) is measured. (I) is found in small amounts in blood, kidney, and spleen. G. H. F.

**Effects of the melanophore hormone and prolantin pigmentation and growth of tadpoles.** M. AGLIALORO and U. CIULLA (Boll. Soc. ital. Biol. D D

sperim., 1935, 10, 538—540).—The melanophore hormone inhibits, whilst prolantin stimulates, these. R. N. C.

**Standardisation of the melanophore hormone.** M. AGLIALORO and U. CIULLA (Boll. Soc. ital. Biol. sperim., 1935, 10, 537—538). R. N. C.

**Villikin in the human intestine.** G. VON LUDANY (Klin. Woch., 1935, 14, 123—124; Chem. Zentr., 1935, i, 3301; cf. A., 1934, 331).—Human intestinal mucous membrane when extracted with HCl, neutralised, and the extract injected intravenously into fasting dogs caused great acceleration of the rate of contraction of villi. G. H. F.

**Colour reactions of vitamin-A, -D, and -E, and of some sterols.** S. UENO, Y. OTA, and Z. UEDA (J. Soc. Chem. Ind. Japan, 1935, 38, 742—744B).—The colour reactions of these vitamins and of cholesterol, ergosterol, and sitosterol, with fourteen new reagents (mainly PhOH + a second substance) are tabulated and briefly discussed. J. W. B.

**Vitamin-A storage of *Macrurus rupestris*.** S. SCHMIDT-NIELSEN, A. FLOOD, J. STENE, and N. A. SØRENSEN (Kong. Norske Vid. Selsk. Forhandl., 1935, 7, 174—177; Chem. Zentr., 1935, i, 3302).—Data for liver-fat and tintometer no. are given and correlated. H. J. E.

**Vitamin-A content of the liver and its variations.** A. CHEVALLIER and Y. CHORON (Compt. rend. Soc. Biol., 1935, 120, 1223—1225).—Vitamin-A (I) is decreased in the liver and increased in the blood of the rabbit by anaesthesia. In the guinea-pig, liver-(I) shows marked variations with the animal, whilst blood-(I) is practically const. R. N. C.

**Metabolism of rat liver in avitaminosis-A.** O. ROSENTHAL (Arch. Neerland. Physiol., 1935, 20, 539—551).—In about 2/3 of the avitaminotic rats examined, the energy of metabolism decreased considerably, and there was a slight decrease in respiration. These effects appeared as often in fatty as in de-fatted livers. Fatty degeneration, probably as a result of the respiration disorder, is assumed. Changes in metabolism and fatty degeneration of the liver are secondary effects of the vitamin-A deficiency. J. N. A.

**Effect of standard diet on liver metabolism in experimental avitaminosis-A in rats.** O. ROSENTHAL (Arch. Neerland. Physiol., 1935, 20, 552—558).—The changes in metabolism and the histological fatty degeneration of the liver are due to an unsp. diet deficiency. The importance of this in the problem of experimental avitaminosis-A is discussed. J. N. A.

**Size and vitamin content of liver of various animals.** S. SCHMIDT-NIELSEN, A. FLOOD, and J. STENE (Kong. Norske Vid. Selsk. Forhandl., 1934, 3, 81—84; Chem. Zentr., 1935, i, 2620).—Vitamin-A contents of livers of warm-blooded animals are < those of many fish. J. S. A.

**Effect of vitamin-A on fat and lipin metabolism.** P. E. SMOLA and T. KALAJA (Suomen Kem., 1935, 8, B, 43—44).—Rats and guinea-pigs fed a vitamin-A (I)-free diet show large decreases in the I val. and neutral fat content of the skin, whereas the cholesterol

content is increased, especially in rats. In rats fed on (I)-rich diets, the free cholesterol of the skin and the cholesteryl esters (II) of the liver and kidneys are increased. In guinea-pigs, the changes are indefinite, although the (II) content, the I val., and the neutral fats of the liver are increased.

J. L. D.

**Fate of carotene injected into the circulation of the rat.** J. C. DRUMMOND and R. J. MACWALTER (*J. Physiol.*, 1934, **83**, 236—242).—Vitamin-A and fat distribution is fairly uniform in the three main lobes of the liver. Carotene injected into the portal circulation is taken up uniformly by the lobes, and tends to disappear after a few days, -A not increasing simultaneously, but in some cases falling. Removal of one lobe may cause a fall in the -A of the other lobes.

R. N. C.

**Vitamin-A in the red corpuscles of the blood of vertebrates.** A. MAGNAN and H. GIRERD (*Compt. rend.*, 1935, **201**, 1219—1221).—Vitamin-A occurs in certain of the red corpuscles of the blood of the ray and is localised on the chondriome.

A. G. P.

**Determination of vitamin-A.** A. L. BACHARACH, J. C. DRUMMOND, and R. A. MORTON (*Nature*, 1936, **137**, 148—149).—A crit. discussion of the three approved methods of standardisation which may give three different results.

L. S. T.

**Effects of vitamin-B on female genital organs of white rats.** J. UENO (*Japan. J. Obstet. Gynecol.*, 1934, **17**, 388—411).

CH. ABS. (p)

**Deficiency of vitamin-B and endocrine glands of female white rats.** J. UENO (*Japan. J. Obstet. Gynecol.*, 1934, **17**, 267—278)

CH. ABS. (p)

**Effect of arginine and of liver and stomach extracts on vitamin-B deficiency in pigeons.** A. VON JENEY (*Klin. Woch.*, 1935, **14**, 379—380; *Chem. Zentr.*, 1935, i, 3155).—The length of life of pigeons on a vitamin-B-free diet was increased by administration of extracts from yeast, liver, or pig's stomach, or of arginine. The -B complex appears to contain an antianæmic factor resembling arginine.

G. H. F.

**Assay of vitamin-B<sub>1</sub> by the "beri-beri" quotient ( $Q_b$ ).** G. AMANTEA (*Atti R. Accad. Lincei*, 1935, [vi], **22**, 173—176).—Further details of the technique are given (cf. A., 1934, 460, 706).

F. O. H.

**Vitamin-B<sub>1</sub> and -B<sub>2</sub>.** J. F. FEASTER and V. E. NELSON (*Proc. Iowa Acad. Sci.*, 1934, **41**, 149—152).—Autoclaved yeast supplies a factor, probably vitamin-B<sub>2</sub>, enhancing lactation in rats.

CH. ABS. (p)

**Interrelationship of vitamins.** C. A. ELVEHJEM and A. ARNOLD (*Nature*, 1936, **137**, 109—110).—The cure of certain symptoms in experimental animals even with cryst. preps. of vitamin does not necessarily mean that the deficiency is due to a lack of the factor fed. Rats showing -B<sub>4</sub>-deficiency may be relieved by administration of -B<sub>1</sub>. The latter appears to relieve accompanying anorexia, and food consumption increases to a level which supplies adequate -B<sub>4</sub>. Synthetic diets used for -B<sub>1</sub> studies must be

amply supplied with -B<sub>4</sub>, especially when growth is used as a criterion of potency. The improved growth often obtained by adding large amounts of -B<sub>1</sub> to rats on a low -B<sub>1</sub> diet may be due to the additional effect of traces of -B<sub>4</sub> present as an impurity.

L. S. T.

**Objective method for fluorescence determination, with special application to the determination of vitamin-B<sub>2</sub>.** F. H. COHEN (*Acta Brev. neerl. Physiol.*, 1935, **5**, 18—19; *Chem. Zentr.*, 1935, i, 3306).—The apparatus previously described (A., 1935, 466) is applied to the determination of vitamin-B<sub>2</sub>.

H. N. R.

**Effect of adenine fed to rats on a diet deficient in vitamin-B<sub>4</sub>.** T. Y. LO (*Nat. Peiping Univ. Coll. Agric. Nutrition Bull.*, 1934, **B**, 1, 40—46).—Pure adenine from yeast does not serve as a source of vitamin-B<sub>4</sub> for rats.

CH. ABS. (p)

**Influence of some food factors on pellagra-like symptoms in rats.** F. J. GORTER (*Z. Vitaminforsch.*, 1936, **5**, 1—11).—The incidence and type of pellagra-like disease in rats depend on the composition of the basal diet. There exists an anti-pellagic growth-promoting factor other than flavin and perhaps identical with vitamin-B<sub>6</sub>. This factor is separated from caseinogen by hydrolysis. Factors causing dermatitis in rats are discussed.

F. O. H.

**Antiscorbutic activity of dehydroascorbic acid: its storage and that of ascorbic acid by the guinea-pig at different levels of intake.** F. W. FOX and L. F. LEVY (*Biochem. J.*, 1936, **30**, 211—217).—The antiscorbutic val. of dehydroascorbic acid has been confirmed (Hirst *et al.*, A., 1933, 1091). After reduction to ascorbic acid (I) it is stored in small amounts in the liver. Storage of (I) in the liver is dependent on the level of intake, being small at the min. protective dose and reaching an upper limit at higher levels.

H. G. R.

**Does vitamin-C affect the occurrence of normal pigmentation?** F. TENCHIO (*Klin. Woch.*, 1934, **13**, 1511—1512; *Chem. Zentr.*, 1934, ii, 3644—3645).

R. N. C.

**Reversibility of oxidation of ascorbic acid.** R. WURMSER and N. MAYER (*Compt. rend. Soc. Biol.*, 1936, **121**, 3—5).—Oxidation of ascorbic acid by 2 : 6-dichlorophenol-indophenol is as reversible as oxidation by I.

R. N. C.

**Reversible oxidation of ascorbic acid by norite charcoal.** F. W. FOX and L. F. LEVY (*Biochem. J.*, 1936, **30**, 208—210).—The C (and to a smaller extent other kinds) rapidly (10—15 min.) converts ascorbic acid almost quantitatively into dehydroascorbic acid. With small amounts of C, the effect  $\propto$  the amount of C. Probably the oxidation results from direct transfer of O<sub>2</sub> from the C surface.

W. McC.

**Biological oxidations.** V. Copper and hæmochromogens as catalysts for the oxidation of ascorbic acid. Mechanism of the oxidation. E. S. G. BARRON, R. H. DEMEIO, and F. KLEMPERER (*J. Biol. Chem.*, 1936, **112**, 625—640).—Ascorbic acid (I) is not autoxidisable in solutions free from Cu when the  $p_H$  is < 7.6. Above  $p_H$  7.6 the rate of

autoxidation increases rapidly with the  $p_H$ . KCN slightly accelerates the rate of  $O_2$  consumption. In neutral and acid solution  $Cu^{++}$  (alone of metallic ions) catalyses the oxidation of (I) in concns. as low as 0.046 mg. of Cu per litre. The  $O_2$  uptake is 1 O per mol. of substrate. The optimum  $p_H$  of the Cu-catalysed oxidation is 6.95. The haemochromogens of nicotine,  $C_5H_5N$ , and pilocarpine can also act as catalysts. 0.001M-KCN completely inhibits the catalytic effect of Cu, and CO, by combining with  $Cu_2Cl_2$  and thus inhibiting its reoxidation to  $CuCl_2$ , also considerably retards the reaction. The low val. of 1.65 for the temp. coeff. suggests that the reoxidation of  $Cu_2Cl_2$  is the reaction governing the rate of oxidation of (I). The oxidation product can be completely reduced by  $H_2S$  up to  $p_H$  5.0, but above this the amount of (I) recovered gradually decreases until at  $p_H$  7.6 the oxidation is mainly irreversible. E. A. H. R.

**Diagnosis of vitamin-C subnutrition by urine analysis.** M. A. ABBASY, L. J. HARRIS, S. N. RAY, and J. R. MARRACK (Lancet, 1935, 229, 1399—1405).—Data obtained by the method previously described (A., 1935, 417), together with its specificity, are discussed. The urinary excretion of vitamin-C by adults receiving graded doses of -C over long periods reaches levels  $\propto$  the intake. Little variation occurs between individual subjects; the same daily dose of -C soon produces an almost identical rate of excretion. During fever, output falls, and an additional dose is needed to restore the original level. A diet appears to be unduly low in -C whenever the daily excretion is  $<$  a titration val. of 10—15 mg. per day per 10 stone body-wt., or when the standard dose of 700 mg. produces no response on the second day. In England, the average daily excretion of normal adults receiving small allowances of fruit or other source of -C is approx. 20 mg. per day. L. S. T.

**Effect of vitamin-C on the growth of plants.** S. VON HAUSEN (Suomen Kem., 1935, 8, B, 50; cf. A., 1935, 1036).—Removal of the cotyledons of young pea seedlings reduces their ascorbic acid (I) content to a low val. and growth is almost completely retarded. Addition of (I) causes increased (approx. normal) growth; the (I) content of the treated plants is much  $>$  that of the untreated. J. L. D.

**Antiscorbutic value of dandelion.** I. S. KLEINER TAUBER (Science, 1935, 82, 552).—The ascorbic acid (I) content varies between 0.08 and 0.10 mg. per g. of fresh greens. Compared with the greens of other vegetables it is not a good source of (I).

L. S. T.

**Ascorbic acid content of plant tissue.** L. ANDOIN, A. GIROUD, and C. P. LEBLOND (Bull. Soc. Chim. biol., 1935, 17, 1649—1676).—Equal quantities of tissue containing chlorophyll and that containing no chlorophyll of the carrot, turnip, cress-grass, endive, lettuce, leek, and beetroot are administered to guinea-pigs in addition to a diet containing no vitamin-C. The chlorophyll tissue has much higher antiscorbutic val., as is shown by the survival curves and the ascorbic acid content of the renal glands, the kidney, liver, and testicles.

A. L.

**Sources of vitamin[-C]. XI—XVI.**—See B, 1936, 121.

**Vitamin-D requirements in relation to the calcium and phosphorus content of the diet.** A. QUERIDO (Arch. Neerland. Physiol., 1935, 20, 487—538; cf. A., 1935, 1431).—The daily requirement for rats varies between 0 and  $1 \times 10^{-6}$  g. of calciferol. It is influenced by the salt level of the ration, and diminishes with increase of the abs. concn. of P. Influence of vitamin-D on the ash content of bone is seen only with diets having a Ca : P ratio of 4. Unpreventable rickets produced by some diets can be changed into a preventable form by preliminary feeding with a diet rich in minerals. Rickets produced by a diet containing 0.2% of P and Ca : P = 1 resembles the human form  $>$  that produced with a Ca : P ratio of 4. J. N. A.

**Evaluation of the relative toxic effects of large doses of calciferol and the crystalline antirachitic preparation substance L.** J. VAN NIEKERK (Arch. Neerland. Physiol., 1935, 20, 559—561).—The ratio of toxic to antirachitic activity of the substance L of Reerink and van Wijk is identical with that of calciferol. J. N. A.

**Anti-infective power of vitamin-D.** G. SPAGNOL (Rev. sudamer. endocrinol., 1935, 18, 163—166).—Irradiated ergosterol prevented infection of rats with *Salmonella typhimurium*. CH. ABS. (p)

**Changes in composition of blood in rabbits by irradiated food.** A. FALASCHINI (Boll. Soc. Eustach., 1934, 32, 1—15; Chem. Zentr., 1934, ii, 3782—3783). R. N. C.

**Irradiation and growth.** F. ROGOZINSKI and Z. GLOWCZYNSKI (Bull. Acad. Polonaise, 1935, B, 123—136).—Ultra-violet irradiation had no apparent influence on the growth, food utilisation, or bone composition of rats receiving a complete diet, but afforded marked protection when a rachitogenic diet was used. A. G. P.

**Cereals and rickets. VI. Comparative rickets-producing properties of different cereals.** B. H. THOMAS and H. STEENBOCK (Biochem. J., 1936, 30, 177—188; cf. Green *et al.*, A., 1928, 333).—Rolled oats, patent flour, whole wheat, polished rice, and yellow maize fed to rats as 75% of a low-Ca diet do not differ as regards the severity of the rickets produced. W. McC.

**Hypervitaminosis-D.** L. THATCHER (Lancet, 1936, 230, 20—22).—Young infants may have idiosyncrasy to the vitamin-D (I) in cod-liver oil as well as to artificially-prepared calciferol. The current tendency to increase the (I) potency of cod-liver oil is deprecated. L. S. T.

**Vitamin-D content of calf, beef, lamb, and hog livers.** G. M. DEVANEY and H. E. MUNSELL (J. Home Econ., 1935, 27, 240—241).—Ox and hog livers have 0.5—0.4, lamb 0.2, and calf liver  $<$  0.1 international units per g. CH. ABS. (p)

**Vitamin-D content of New Zealand fish oils : prophylactic method of biological assay.** M. M. CUNNINGHAM (New Zealand J. Sci. Tech., 1935, 17, 563—567).—Vals. for a no. of oils are recorded.

That for proper-liver oil was exceptionally high. The trustworthiness of the prophylactic method of assay is confirmed. A. G. P.

**Vitamin-E. IV. Influence on fertility and condition of the young.** L. SCHIOPPA (Z. Vitaminforsch., 1936, 5, 22—26).—Administration of large doses of wheat-germ oil to doe rabbits increases their fertility and body-wt. F. O. H.

**Chemical properties of vitamin-E.** H. S. OLCOTT (Proc. Iowa Acad. Sci., 1934, 41, 173; cf. A., 1935, 1431).—The inactive product obtained by bromination of vitamin-E concentrates is reactivated by boiling with Zn and HCl in MeOH. Catalytic hydrogenation at 200°/200 atm. does not destroy -E.

CH. ABS. (p)

**Newly-discovered nutritional factor in milk.** G. VON WENDT (Z. Volksernahr., 1935, 10, 116—118; Chem. Zentr., 1935, i, 3686).—The milk of cows fed with green food contains a nutritional factor that stimulated growth and lacteal secretion in rats and in a nursing woman. It is not stored in the organism, nor bound to the milk fat. It is stable to drying of the milk, but not to drying for hay of the grass fed to the cows. R. N. C.

**Relationships between the chemistry of chlorophyll and its function in photosynthesis.** A. STOLL (Naturwiss., 1936, 24, 53—59).—A lecture.

**Photosynthesis in *Grimmia montana*.** E. MCKAY (Plant Physiol., 1935, 10, 803—809).—Photosynthesis begins within 10—20 min. of moistening the dry moss, and reaches equilibrium with respired CO<sub>2</sub> in 30 min. The reducing sugar contents of the plant increase from the beginning of photosynthesis and reach a steady level after 30 min.

A. G. P.

**Photochemical responses of wheat plant to spectral regions.** E. J. LEASE and W. E. TOTTINGHAM (J. Amer. Chem. Soc., 1935, 57, 2613—2616).—Elimination of  $\lambda < 390$  or 520 m $\mu$  from artificial sunlight decreases the assimilation of NO<sub>3</sub>' (I) and conserves carbohydrates in young wheat plants. The chlorophyll and SH-compounds in the tissue also decrease; these appear to influence the reducing power of the press sap. Increased assimilation of (I) is accompanied by a reduction in the pentosans. Most of the compositional effects in the tissue are associated with variations in the proportion of blue-violet light. Reduction of (I) to NO<sub>2</sub>' is, however, associated with long ultra-violet radiation. H. B.

**Histological variations in *Cosmos* in relation to photoperiodism.** O. BIDDULPH (Bot. Gaz., 1935, 97, 139—155).—Short-day treatment of *C. sulphureus* causes rapid initiation of flower primordia (7 days). Transition of foliar to flower primordia is accompanied by marked accumulation of carbohydrates and protein in the growing tip, and by hydrolysis of these at the base of the stem. The glutathione content of the tip shows diurnal variations during the short-day treatment, but remains permanently high from the time of the actual anatomical change from vegetative to flower primordia. Flower-bud formation is associated with somewhat higher asparagine and lower NH<sub>4</sub>' contents in the stem tip. A. G. P.

**Modification of [plant] leaf structure by X-rays.** Y. NOGUCHI (Plant Physiol., 1935, 10, 753—762).—Localised modifications of cellular structure and of the distribution of chloroplasts follow exposure to X-rays.

A. G. P.

**Theory of assimilation.** H. GAFFRON and K. WOHL (Naturwiss., 1936, 24, 81—90, 103—107).—A discussion.

**Metabolism of certain *Chlorella* and allied forms.** T. D. BECKWITH (Publ. Univ. Calif. Biol. Sci., 1933, 1, No. 1, 1—34).—Three among 8 examined species of unicellular algae produced NO<sub>2</sub>' from NO<sub>3</sub>'. None effected the reverse change, although several species grew well on NO<sub>2</sub>' media. As source of N urea was generally unsuitable, asparagine had a depressive action, peptone was favourable to some species, and in one case (NH<sub>4</sub>)<sub>2</sub>CO<sub>3</sub> was satisfactorily utilised. The end-products of N metabolism were bases. Neither indole nor tryptophan was formed. Complete protein was not essential to these organisms. In diffuse light only maltose and glucose favoured proliferation. The end-products of carbohydrate metabolism were alkaline whether grown in darkness or in light. The antigenic protein structure of *Chlorella* varies with the species.

A. G. P.

**Phosphorus metabolism in leaves of persistent-foilage plants, during yellowing.** E. MICHEL-DURAND (Compt. rend., 1935, 201, 1215—1217; cf. A., 1935, 265).—Fractionation of the P compounds of end-of-season green leaves and of yellowed leaves is recorded. Small amounts of phytin-P occurred in all green leaves. On yellowing this migrated completely in Algerian ivy and *Aucuba* (but not in cherry-laurel) before actual leaf-fall. Other forms of P declined in varying proportions at this stage.

A. G. P.

**Lipin metabolism in germinating mung bean.** H. C. KAO (Biochem. J., 1936, 30, 202—207).—During germination the N and ash contents of the whole bean (*Phaseolus aureus*) remain const., the amounts of Et<sub>2</sub>O and EtOH extracts increase, the chief constituents of the cotyledon are gradually transferred to the germinating portion, the sterols increase, and the phosphatides decrease. The total fatty acids first decrease and then increase. In the cotyledon the amount of fatty acids remains const., but the amount in the growing portion increases. The degree of saturation of the fatty acids in the sprouting portion increases.

W. McC.

**Effect of an atmosphere enriched in oxygen on development of plants.** M. MOLLARD (Compt. rend., 1935, 201, 1160—1162).—Dry matter production by radish plants decreased with rising [O<sub>2</sub>] (20—80% of the atm., probably as a result of chlorophyll injury. *A. niger* was similarly affected, but to a relatively smaller extent. In a current of O<sub>2</sub>, conidia produced after exhaustion of sugar in the medium were coloured brick-red.

A. G. P.

**Structure of the walls of higher plants.** D. B. ANDERSON (Bot. Rev., 1935, 1, 52—76).—A review.

CH. ABS. (p)

**Physiological characteristics of frost-resistant winter grains.** M. T. TIMOFEEV (Bull. Appl.

U.S.S.R., 1934, Ser. A, No. 9, 17—24).—The significance of the proteins, the  $p_H$  of the sap, and other physicochemical properties, in addition to the sugar and  $H_2O$  contents, is emphasised. CH. ABS. (p)

**Distribution of plant constituents in capillary form. II. Fluorescence of chlorophyll.** A. KUHN and G. SCHAFER (Pharm. Zentr., 1936, 77, 33—35).—With capillary formation, the green zone of chlorophyll (e.g., from tinctures) as viewed by daylight becomes black or red by filtered ultra-violet light. This is due to presence of essential or fatty oils. F. O. H.

**Cause of cold-resistance in plants.** W. KESSLER (Planta, 1935, 24, 312—352).—No causal relationship exists between cold-resistance and the osmotic pressure or  $[H^+]$  of the cell sap. The winter resting period of the plant is associated with changes in the condition of the plasma resulting in increased viscosity and hydration of the colloids and probably with greater  $d$  of the plasma. A. G. P.

**Course of stone cell formation in pear fruits.** W. W. SMITH (Plant Physiol., 1935, 10, 587—611).—Changes in the lignin, cellulose, reducing substances, and  $H_2O$ -, alkali-, and EtOH-extractives during the development of the fruit are recorded. The decrease in the % of lignocellulose (I) during growth of certain varieties of apple and pear is due not to a decline in abs. amounts present, but to a relatively rapid increase in EtOH-extractives. There is no evidence of a breakdown of (I) to simpler substances. Sugars are probably elaborated to form lignified tissue. Hemicellulose disappears during storage of fruit and probably serves as a source of respirable matter. A. G. P.

**Osmotic pressure and water content of prairie s.** L. A. STODDART (Plant Physiol., 1935, 10, 680).—The osmotic pressure of plant saps is characteristic of environment, i.e., the resultant of soil forces which supply  $H_2O$  and transpiration effects. A close inverse relationship is established between the osmotic pressure and  $H_2O$  contents of indi plants. The osmotic pressure in new was > that in old tissue. A. G. P.

**Comparison of the plasmolytic and cryoscopic methods for determining osmotic values in plants.** BUHMANN (Protoplasma, 1935, 23, 579).—Appropriate technique is described. The two methods yield comparable results. Extensive experimental data are recorded and discussed.

**Freezable and freezable water equilibrium in plant tissues as influenced by sub-zero temperatures.** A. GREATHOUSE (Plant Physiol., 1935, 10, 781—8).—The conception that normally "unfreezable"  $H_2O$  in plant tissues does actually freeze at low temp. ( $-18^\circ$  to  $-20^\circ$ ) applies to hardened but not to unhardened clover-root tissue or to potato tubers. A. G. P.

**Streamline flow and the movement of solutes in the transpiration stream.** R. C. McLEAN and I. R. CHINGS (Plant Physiol., 1935, 10, 773—780).—The diffusion of solutes in plants may be explained by consideration of the radical velocity

gradient due to streamline flow in tubes. Movement of solutes in the  $H_2O$  stream of the xylem may be considerably more rapid than that indicated by transpiration data. A. G. P.

**Temperature regulation of the dry matter production in marine algae as a plasmatic adjustment.** H. LAMPE (Protoplasma, 1935, 23, 534—578).—Respiration rates and the assimilation/respiration quotient of several species of marine algae are examined in relation to temp. and seasonal changes and to the distribution of species. A. G. P.

**Influence of the carbohydrate-nitrogen relation on nodule production by red clover.** C. E. GEORGI (J. Agric. Res., 1935, 51, 597—612).—The inhibitory action on nodulation of combined-N feeding of clover plants is partly counteracted by increasing carbohydrate synthesis, e.g., by  $CO_2$ -enrichment. The inhibitory influence is associated with increased concn. of sol. carbohydrates, and decreased % of N and concn. of inorg. N in the sap. A. G. P.

**Possible structure of chlorophyll granules in the plastid.** J. G. WAKKIE (Proc. K. Akad. Wetensch. Amsterdam, 1935, 38, 1082—1086).—Additional support is given for the granular model of the plastid. Anisotropic colloidal chlorophyll (I) models were made, which fluoresced in a hydrophilic environment by association with a "carrier-mol." Owing to the low concn. of (I) the models did not possess the required band spectrum. The results are in agreement with data for the diffusion of (I) in paraffin and MeOH. J. N. A.

**Formation of cell-wall substance [in plants].** A. KIESEL and R. JATZINA (Planta, 1935, 24, 308—311).—Both  $H_2O$ - and EtOH-sol. galacturonic acids occur on the cell wall. The EtOH-sol. form is probably stored within the cell. A transition into EtOH-insol. and probably into  $H_2O$ -insol. forms in the cell wall is indicated. A. G. P.

**Slime flux [of trees].** E. F. GUBA (10th Nat. Shade Tree Conf. Proc. Ann. Meet., 1934, 56—60).—Exudates from heartwood of shade trees become gritty through deposition of  $CaCO_3$  dissolved from cell walls. Exudates are alkaline and favour growth of numerous organisms. Exudates from wounds in inner bark or sapwood are usually acid and rich in sugars, proteins, and starch: many contain  $BzOH$ ,  $H_2C_2O_4$ , cinnamic acid, and traces of  $MeCHO$  and  $PhCHO$ . CH. ABS. (p)

***Digitalis lanata* and *D. purpurea*: comparative biological investigation.** E. BERTONASCO (Giorn. Farm. Chim. Sci. aff., 1934, 83, 421—424; Chem. Zentr., 1935, i, 3690). R. N. C.

**Plant pigments and reproduction.** R. H. ROBERTS and N. LIVINGSTON (Science, 1935, 82, 596).—With apple leaves, no correlation between fruitfulness and the carotenoid pigments could be detected (cf. A., 1934, 1045). L. S. I.

**Assimilation and respiration of Mediterranean macchia plants in rainy and dry seasons.** H. VON GUTTENBERG and H. BUHR (Planta, 1935, 24, 163—265).—Daily and seasonal changes in assimilation

ation and respiration rates and in the starch and sugar contents of leaves are recorded. The influence of temp., light conditions, and  $H_2O$  supply is examined.

A. G. P.

**Gaseous exchange in aquatic plants during photosynthesis.** F. GÓRSKI (Bull. Acad. Polonaise, 1935, B, 177—198).—Factors affecting the results of the "bubble" method are examined. Most of the  $O_2$  produced (70%) diffuses in the  $H_2O$ , the balance escaping in bubbles. Relatively less N passes from the  $H_2O$  into the intercellular spaces at higher rates of assimilation, since the rate of diffusion is slow. The size of the plant has little influence on the relative amounts of gases evolved.

A. G. P.

**Kinetics of an intracellular system for respiration and bioelectric potential at fluxequilibrium.** G. MARSH (Plant Physiol., 1935, 10, 681—697).—Mathematical.

A. G. P.

**Absorption and accumulation of potassium bromide by *Elodea* as related to respiration.** R. S. ROSENFELS (Protoplasma, 1935, 23, 503—519).—In *Elodea* tissue immersed in aq. KBr, artificially induced changes in respiration rate were paralleled by similar changes in  $Br^-$  absorption. The mechanism of these effects is discussed.

A. G. P.

**Hormones in relation to root formation on stem cuttings.** W. C. COOPER (Plant Physiol., 1935, 10, 789—794).—Application of  $\beta$ -indolylacetic acid to leafy or leafless cuttings of lemon and other species stimulates root formation. The hormone is translocated in the phloem.

A. G. P.

**Chemical nature of some growth hormones as determined by the diffusion method.** A. N. J. HEYN (Proc. K. Akad. Wetensch. Amsterdam, 1935, 38, 1074—1081).—The growth hormone from root tips of *Vicia faba* is identical with auxin, and the latter is probably present in the regenerated tip of the coleoptile of *Avena*. The hormone obtained from the sporangiophore of *Phycomyces nitens* is probably  $\beta$ -indolylacetic acid.

J. N. A.

**Follicular and other hormones and plant growth.** M. A. H. TINCKER and S. E. JACOBS (Ann. Appl. Biol., 1935, 22, 619—629).—Administration of ketohydroxyœstrin and theelol to plants, by the roots, by injection, or by application to cut surfaces failed to produce any growth response or acceleration of flowering. Auxin stimulated the growth of *Bacterium auxinophilum* (nov. sp.) isolated from gelatin cultures of greenhouse cuttings.

A. G. P.

**Influence of ovarian hormone on plant development.** G. TEODORO and R. ZAMPETTI (Arch. Ist. Biochim. Ital., 1935, 7, 425—440).—The cryst. hormone tends to inhibit germination of some plants, but stimulates the subsequent growth especially of the roots (e.g., with *Lens esculenta*). Variations occur with different plants and also with different culture media.

F. O. H.

**Effect of artificial wind on growth and transpiration in *Helianthus annuus*.** E. V. MARTIN and F. E. CLEMENTS (Plant Physiol., 1935, 10, 613—636).

A. G. P.

**Action of sulphurous mineral waters on germination and plant development.** P. TESTONI (Annali Chim. Appl., 1935, 25, 558—563).—Mineral  $H_2O$  (analyses given) of Tivoli and Telese produces more rapid germination and growth of wheat and lentil than does normal  $H_2O$ .

F. O. H.

**Growth and seasonal changes in composition of oak leaves.** A. W. SAMPSON and R. SAMSON (Plant Physiol., 1935, 10, 739—751).—Protein (I) and fibre accumulate in the leaves at an early stage of growth. Assimilation of N ceases for a considerable period during active leaf expansion. Fibre production proceeds, only very slowly. Resorption of (I) of older leaves occurs in the late growth stage. The  $Et_2O$ -extractives increase steadily throughout growth. Accumulation of N-free extractives varies with the location. Rates of intake of Ca, Si, K, and P varied individually with advancing growth.

A. G. P.

**Formation of ethylene by plant tissues and its significance in the ripening of fruit.** R. GANE (J. Pomology, 1935, 13, 351—358).—Ripe apples generate gaseous products which produce epinastic effects on petioles and leaves of plants and abnormal growth of seedlings similar to those produced by  $C_2H_4$ . Esters evolved by ripe apples do not affect seedlings.  $C_2H_4$  is isolated from the "active substance" of apples (cf. A., 1935, 265).

A. G. P.

**Effects of ethylene on plant-growth hormone.** H. D. MICHENER (Science, 1935, 82, 551—552).—Experiments in which  $C_2H_4$  acts on plant growth in a manner different from heteroauxin are described. Action of  $C_2H_4$  on growth may be explained, not as direct effects of  $C_2H_4$  alone, but as effects of  $C_2H_4$  on a growth hormone.

L. S. I.

**Germination experiments with peas in heavy water.** J. BRUN and L. TRONSTAD (Kongl. Norske Vid. Selsk. Forh., 1935, 7, 171—173; Chem. Zentr., 1935, i, 3242).—Germination occurred in  $H_2O$  containing  $> 40\%$   $D_2O$ , but was inhibited at higher concns. Algal growth occurred up to  $94\%$   $D_2O$ .

J. S. A.

**Effect of the pyrrole nucleus on the formation of chlorophyll.** G. POLACCI, B. ODDO, and M. GALLOTTI (Boll. Soc. ital. Biol. sperim., 1935, 10, 565—567).—Growth of algæ and formation of chlorophyll are not opposed by Mg pyrrole-2-carboxylate.

**Influence of sulphur deficiency on the metabolism of soya bean.** S. V. EATON (Bot. Gaz., 1935, 97, 68—100).—External symptoms of S deficiency resemble those of N, P, or K deficiency in many respects, and are probably the immediate effect of inferior assimilation of  $NO_3^-$  within the plant. Stem elongation is only slightly reduced by S deficiency, largely because of the ability of the soya bean to break down and re-utilise protein. Plants lacking S produce harder stems. Cell-wall thickness is more closely related to the accumulation of starch and hemicellulose (I) than to that of total carbohydrates. (I) probably acts as a reserve material. S-deficient plants contain much sol. org. N, but have a low sugar content. Proteolysis is active but resynthesis is incomplete through inadequacy of the S supply.

A. G. P.

**Biochemical modifications in phytopathology :** carbohydrate substances of the leaf of *Ampelopsis vitifolia*, Hort. R. SALGUES (Compt. rend. Soc. Biol., 1935, 120, 1212—1214).—Sol. polysaccharides in the healthy leaf increase during the late summer and fall in autumn, whilst insol. polysaccharides fall rapidly in summer and more slowly in autumn. In the leaf affected with *Phyllosticta altescheri*, Syd., the changes are similar but retarded. R. N. C.

**Effect of titanous chloride on the formation of chlorophyll in *Zea mays*.** O. L. INMAN, G. BARCLAY, and M. HUBBARD (Plant Physiol., 1935, 10, 821—822).—In chlorophyll formation Ti cannot replace Fe. Addition of Fe to nutrient media increases root formation. A. G. P.

**Calcium deficiency effects on *Pisum sativum*.** D. DAY (Plant Physiol., 1935, 10, 811—816).—Insufficient supplies of Ca are associated with shorter and less succulent growth, high % of dry matter in the tops and low % in the roots, and low Ca content in the whole plant. A. G. P.

**Serological studies of plant viruses.** J. M. BIRKELAND (Ann. Appl. Biol., 1935, 22, 719—727).—Precipitin reactions with plant viruses cultivated in serologically unrelated hosts show that the virus is, in itself, antigenic. Viruses of cucumber mosaic, tobacco ring-spot, and tobacco mosaic are serologically distinct, whereas tobacco mosaic, aucuba mosaic, and probably tomato streak virus are indistinguishable. A. G. P.

**Properties of virus causing degeneration diseases of beet.** G. VERPLANCKE (Succerie belge, 1935, 54, 118—127, 142—151, 162—168; Chem. Zentr., 1935, i, 3210).—The properties of the virus causing yellowing and mosaic diseases of beet leaves, and its resistance towards temp. and chemical agents, are reviewed. The virus in purified solutions is more sensitive than that in the juice. J. S. A.

**Chlorosis of hortensia (*Hydrangea hortensis*) in relation to iron.**—See B., 1936, 165.

**Effects of fuel oil on plants.** G. D. FULLER and DRETTNER (Plant Physiol., 1935, 10, 817—820).—Fuel oil injures plants when brought into contact with them, the effect becoming fatal when the quantity reaches a level critical for each species. Penetration of oil may not occur, but if it enters the root it acts principally in the primary xylem. A. G. P.

**Chemical composition of grasses in pure culture at different stages of growth.**—See B., 1936, 169.

**Content of plants and water.** B. K. SKI and K. G. KUNASCHIEVA (Trav. lab. Acad. Sci. U.S.S.R., 1935, 3, 31—41).—The content of plants varied from 0.89 to 20.5% on contained 10 times as much  $\text{H}_2\text{O}$  as the sea  $\text{H}_2\text{O}$  from which they were obtained. Yeast contained amounts of the same order. CH. ABS. (p)

**Comparative sulphur and phosphorus content of plants grown in the same soil.** G. BERTRAND and I. SILBERTEIN (Compt. rend., 1935, 201, 1449—1453).—The S/P ratio in the foliage of many plants grown under the same conditions varies from 0.377

to 4.021, which indicates that the S or P content depends on the physiological requirements of the plant. The capacity to "fix" S, probably present in org. combination, is more variable than for P.

J. L. D.

**Constituents of *Orthosiphon stamineus*, Benth.** R. DIETZEL and E. SCHMIDT (Arch. Pharm., 1936, 274, 10—16).—Cold and hot aq. extracts of *O. stamineus* are treated with urease at  $pH$  7.2 and the  $\text{CO}_2$  (modified Barcroft method) and  $\text{NH}_3$  liberated determined. 100 g. of air-dried drug contain 14 mg. of free and a further 26 mg. of combined urea.

R. S. C.

**Occurrence of piperidine in black pepper.** E. SPATH and G. ENGLAENDER (Ber., 1935, 68, [B], 2218—2221).—Distillation of a mixture of finely divided black pepper and  $\text{MgO}$  with steam in vac. at  $35^\circ$  affords an alkaline distillate which after neutralisation with  $\text{HCl}$  gives a mixture of  $\text{NH}_4\text{Cl}$  and piperidine hydrochloride separable by  $\text{CHCl}_3$ . Under these conditions piperine is not hydrolysed. Since similar results are obtained with an aq. extract of pepper free from piperine the presence of piperidine (0.0086%) as such or as a simple salt is established. The presence of 3-methylpyrrolidine could not be confirmed.

H. W.

**Odoriferous constituent of *Periploca graca*, L.** T. SOLACOLU, A. MAYRODIN, and G. HERRMANN (J. Pharm. Chim., 1935, [viii], 22, 548—556).—The bark contains 2-hydroxy-4-methoxybenzaldehyde, which is distributed fairly widely in the *Asclepiadaceae*.

J. L. D.

**Acids contained in the wood of *Libocedrus formosana*, Florin.** VII. N. ICHIKAWA (J. Chem. Soc. Japan, 1934, 55, 1124—1133).—Oxidation experiments with dihydroshonan acid indicate the presence of the 3-carboxy-6-methylene- $\Delta^4$ -cyclohexyl grouping in shonan acid.

CH. ABS. (r)

**Bark of *Terminalia arjuna*, Bedd.** I. Isolation of arjunin. R. R. AGARWAL and S. DUTT (Proc. Acad. Sci. Agra and Oudh, 1934—1935, 5, 50—54).— $\text{C}_6\text{H}_6$  extracts arjunin,  $\text{C}_{26}\text{H}_{40}\text{O}_{11}$ , m.p.  $192^\circ$  (decomp.) [ $\text{Pb}$ ,  $\text{Ag}$ , and  $\text{Na}$  salts;  $\text{Ac}_2$  and  $\text{Bz}_2$  derivatives, m.p.  $103^\circ$  and  $207^\circ$ , respectively; ( $\text{NO}_2$ )<sub>5</sub>-derivative, m.p.  $118^\circ$ ], from the bark. The substance is sol. in  $\text{NaHCO}_3$  and gives many colour reactions.

J. L. D.

**Lichen substances.** LXII.—See this vol., 314.

**Colouring matter of flowers of *Kerria japonica*, DC.** T. ITOUGH, H. SUGINOME, and K. UENO (J. Chem. Soc. Japan, 1934, 55, 1101—1105).—In the colouring wax the palmitate with smaller amounts of the oleate of lutein was the chief constituent.

CH. ABS. (p)

**Pigments of cotton flowers.** II. Uppam (*Gossypium herbaceum*). K. NEELAKANTAM, T. R. SESHADRI, and R. H. R. RAO (Proc. Indian Acad. Sci., 1935, 2, A, 490—496).—Petals of *G. herbaceum* from Coimbatore, South India, differ from those (from North India?) studied by A. G. Perkin (A., 1916, i, 280) in containing gossypitrin and quercetin (instead of isoquercetin), and a new flavonol monoglucoside, m.p.  $247^\circ$ — $249^\circ$ , with small quantities of gossypetin (cf. A., 1929, 326). E. W. W.

ation and respiration rates and in the starch and sugar contents of leaves are recorded. The influence of temp., light conditions, and  $H_2O$  supply is examined.

A. G. P.

**Gaseous exchange in aquatic plants during photosynthesis.** F. GÓRSKI (Bull. Acad. Polonaise, 1935, B, 177—198).—Factors affecting the results of the "bubble" method are examined. Most of the  $O_2$  produced (70%) diffuses in the  $H_2O$ , the balance escaping in bubbles. Relatively less N passes from the  $H_2O$  into the intercellular spaces at higher rates of assimilation, since the rate of diffusion is slow. The size of the plant has little influence on the relative amounts of gases evolved.

A. G. P.

**Kinetics of an intracellular system for respiration and bioelectric potential at fluxequilibrium.** G. MARSH (Plant Physiol., 1935, 10, 681—697).—Mathematical.

A. G. P.

**Absorption and accumulation of potassium bromide by *Elodea* as related to respiration.** R. S. ROSENFELS (Protoplasma, 1935, 23, 503—519).—In *Elodea* tissue immersed in aq. KBr, artificially induced changes in respiration rate were paralleled by similar changes in  $Br^-$  absorption. The mechanism of these effects is discussed.

A. G. P.

**Hormones in relation to root formation on stem cuttings.** W. C. COOPER (Plant Physiol., 1935, 10, 789—794).—Application of  $\beta$ -indolylacetic acid to leafy or leafless cuttings of lemon and other species stimulates root formation. The hormone is translocated in the phloem.

A. G. P.

**Chemical nature of some growth hormones as determined by the diffusion method.** A. N. HEYN (Proc. K. Akad. Wetensch. Amsterdam, 1935, 38, 1074—1081).—The growth hormone from root tips of *Vicia faba* is identical with auxin, and the latter is probably present in the regenerated tip of the coleoptile of *Avena*. The hormone obtained from the sporangiphore of *Phycomyces nitens* is probably  $\beta$ -indolylacetic acid.

J. N. A.

**Follicular and other hormones and plant growth.** M. A. H. TINCER and S. E. JACOBS (Ann. Appl. Biol., 1935, 22, 619—629).—Administration of ketoxyhydroxycastrin and theelol to plants, by the roots, by injection, or by application to cut surfaces failed to produce any growth response or acceleration of flowering. Auxin stimulated the growth of *Bacterium auxinophilum* (nov. sp.) isolated from gelatin cultures of greenhouse cuttings.

A. G. P.

**Influence of ovarian hormone on plant development.** G. TEODORO and R. ZAMPETTI (Arch. Ist. Biochim. Ital., 1935, 7, 425—440).—The cryst. hormone tends to inhibit germination of some plants, but stimulates the subsequent growth especially of the roots (e.g., with *Lens esculenta*). Variations occur with different plants and also with different culture media.

F. O. H.

**Effect of artificial wind on growth and transpiration in *Helianthus annuus*.** E. V. MARTIN and F. E. CLEMENTS (Plant Physiol., 1935, 10, 613—636).

A. G. P.

**Action of sulphurous mineral waters on germination and plant development.** P. TESTONI (Annali Chim. Appl., 1935, 25, 558—563).—Mineral  $H_2O$  (analyses given) of Tivoli and Telese produces more rapid germination and growth of wheat and lentil than does normal  $H_2O$ .

F. O. H.

**Growth and seasonal changes in composition of oak leaves.** A. W. SAMPSON and R. SAMISCH (Plant Physiol., 1935, 10, 739—751).—Protein (I) and fibre accumulate in the leaves at an early stage of growth. Assimilation of N ceases for a considerable period during active leaf expansion. Fibre production proceeds, only very slowly. Resorption of (I) of older leaves occurs in the late growth stage. The  $Et_2O$ -extractives increase steadily throughout growth. Accumulation of N-free extractives varies with the location. Rates of intake of Ca, Si, K, and P varied individually with advancing growth.

A. G. P.

**Formation of ethylene by plant tissues and its significance in the ripening of fruit.** R. GANE (J. Pomology, 1935, 13, 351—358).—Ripe apples generate gaseous products which produce epinastic effects on petioles and leaves of plants and abnormal growth of seedlings similar to those produced by  $C_2H_4$ . Esters evolved by ripe apples do not affect seedlings.  $C_2H_4$  is isolated from the "active substance" of apples (cf. A., 1935, 265).

A. G. P.

**Effects of ethylene on plant-growth hormone.** H. D. MICHENER (Science, 1935, 82, 551—552).—Experiments in which  $C_2H_4$  acts on plant growth in a manner different from heteroauxin are described. Action of  $C_2H_4$  on growth may be explained, not as direct effects of  $C_2H_4$  alone, but as effects of  $C_2H_4$  on a growth hormone.

L. S. T.

**Germination experiments with peas in heavy water.** J. BRUN and L. TRONSTAD (Kongl. Norske Vid. Selsk. Forh., 1935, 7, 171—173; Chem. Zentr., 1935, i, 3242).—Germination occurred in  $H_2O$  containing  $> 40\%$   $D_2O$ , but was inhibited at higher concns. Algal growth occurred up to 94%  $D_2O$ .

J. S. A.

**Effect of the pyrrole nucleus on the formation of chlorophyll.** G. POLACCI, B. ODDO, and M. GALLOTTI (Boll. Soc. ital. Biol. sperim., 1935, 10, 565—567).—Growth of algae and formation of chlorophyll are not opposed by Mg pyrrole-2-carboxylate.

R. N. C.

**Influence of sulphur deficiency on the metabolism of soya bean.** S. V. EATON (Bot. Gaz., 1935, 97, 68—100).—External symptoms of S deficiency resemble those of N, P, or K deficiency in many respects, and are probably the immediate effect of inferior assimilation of  $NO_3^-$  within the plant. Stem elongation is only slightly reduced by S deficiency, largely because of the ability of the soya bean to break down and re-utilise protein. Plants lacking S produce harder stems. Cell-wall thickness is more closely related to the accumulation of starch and hemicellulose (I) than to that of total carbohydrates. (I) probably acts as a reserve material. S-deficient plants contain much sol. org. N, but have a low sugar content. Proteolysis is active but resynthesis is incomplete through inadequacy of the S supply.

# BRITISH CHEMICAL ABSTRACTS

## A.—PURE CHEMISTRY

APRIL, 1936.

### General, Physical, and Inorganic Chemistry.

Intensity variation in the fine structure of the Balmer lines  $H_\alpha$  and  $H_\beta$ . B. SVENSSON (Physica, 1936, 3, 91—104).—Data are recorded for the intensity ratio ( $I_k/I_l$ ) of short- and long-wave components, for pressures of 0.005—0.8 mm. at different c.d. With varying pressure, the transition from non-striated to striated discharge corresponds with a discontinuity in the  $I_k/I_l$  vals. L. J. J.

Comparison of theoretical and empirical values for Stark effect displacement of the components of  $H_\gamma$ ,  $\pi 18$ . K. BASU (Z. Physik, 1936, 98, 576—579). A. B. D. C.

Source of doubly ionised helium. O. LUHR (Physical Rev., 1936, [ii], 49, 317—319).—A magnetron type of low-voltage arc, giving about 2%  $He^{++}$  by multiple electron impact, is described. N. M. B.

Zeeman effect in helium. L. E. KINSLER and W. V. HOUSTON (Physical Rev., 1934, [ii], 46, 533—534).—The anomalous effect previously reported (A., 1935, 1437) is due to an experimental error. The val. of  $e/m$  obtained from Zeeman splitting of singlet lines of Zn, Cd, He, and Ne is  $1.7570 \pm 0.0007 \times 10^7$  e.m.u. per g. L. S. T.

Analysis of  $3d-4f$  for C II, N III, and N II. Intercombinations in C II and N III. B. EDLÉN (Z. Physik, 1936, 98, 561—568). A. B. D. C.

New members of the Lyman-Birge-Hopfield system [of  $N_2$ ]. J. KAPLAN and L. D. LEVANAS (Physical Rev., 1934, [ii], 46, 331).—A max. val. of 7.7 volts for  $D(N_2)$  is obtained. L. S. T.

New bands of the ionised nitrogen molecule. F. H. CRAWFORD and P. M. TSAI (Physical Rev., 1934, [ii], 46, 935).—400 new lines have been assigned in the  $2\Sigma-2\Sigma$  bands of  $N_2^+$ . L. S. T.

Zeeman effect in the atmospheric oxygen bands; production of a strong magnetic field over a length of 80 cm. R. SCHMID (Physical Rev., 1936, [ii], 49, 271).—A means of obtaining fields over the lengths necessary for the Zeeman effect is described. A qual. discussion of the observed effect is given. N. M. B.

Oxygen afterglow. E. M. STODDART (Proc. Roy. Soc., 1935, A, 153, 152—157).—A reply to Rayleigh's criticisms (A., 1935, 907). Experiments are described showing the effects on the  $O_2$  afterglow of  $H_2O$  vapour in the gas phase and adsorbed on the surfaces of the vessels, which are in agreement with the results of other investigators. L. L. B.

Zeeman effect in neon. L. E. KINSLER (Physical Rev., 1934, [ii], 46, 533).—Measurements of the

Zeeman splitting of the Ne lines 5852 and 6074 Å. indicate that the  $g$ -sum rule is valid to  $< 0.1\%$ ; assuming the validity of this rule,  $e/m$  is  $1.7580 \pm 0.0014 \times 10^7$  e.m.u. per g. L. S. T.

Series lines of magnesium in the solar spectrum. H. N. RUSSELL, H. D. BABCOCK, and C. E. MOORE (Physical Rev., 1934, [ii], 46, 826—827).—Members of the series  $3^1D-n^1F^0$  and  $3^3D-n^3F^0$  observed in the arc spectrum of Mg (A., 1932, 315), together with additional members, have been found in the infra-red solar spectrum. L. S. T.

Spectra of phosphorus. I. Spectra of neutral and singly-ionised phosphorus. H. A. ROBINSON (Physical Rev., 1936, [ii], 49, 297—305).—Using the discharge emitted by a Geissler tube containing P vapour, 22 new terms classifying 36 lines of P I were located; these lines also appear in a 25-amp. C arc containing  $Ca_3P_2$ . The revised ionisation potential is approx. 10.9 volts. 52 new terms classifying 194 lines in the Schumann and visible regions were located in P II. The singlet and triplet sequences are located from more than 20 inter-system combinations. Full data for classified lines of P I and P II are tabulated. The revised P II ionisation potential is 19.56 volts. N. M. B.

Band spectrum of sulphur and the statistics of the sulphur nucleus. R. M. BADGER (Physical Rev., 1934, [ii], 46, 1025—1026).—The analysis made by Naudé and Christy (A., 1931, 540) is criticised. Consts. of the S mol. are revised. L. S. T.

Nuclear mechanical and magnetic moments of  $K^{39}$ . D. A. JACKSON and H. KUHN (Nature, 1936, 137, 108; cf. A., 1935, 555).—Photometric measurements of the intensities of the hyperfine structure doublets of the resonance lines of K show that the shorter- $\lambda$  component is the stronger, thus establishing that the magnetic moment of the nucleus of  $K^{39}$  is negative. The val. calc. is  $-0.39$  nuclear magneton. L. S. T.

Hyperfine structure of some vanadium multiplets. H. KOFFERMANN and E. RASMUSSEN (Z. Physik, 1936, 98, 624—637).—The mechanical moment of the V nucleus is  $7/2$ . A. B. D. C.

Photographic photometry of iron multiplets in electric furnace spectra. R. B. KING (Physical Rev., 1934, [ii], 46, 327). L. S. T.

Band spectra of rubidium and of its combinations with other alkali metals. P. KUSCH (Physical Rev., 1936, [ii], 49, 218—222).—The magnetic rotation spectrum and absorption spectrum

of  $\text{Rb}_2$  in the region 6500—7100 Å. have been measured and correlated and a vibrational analysis is given. The vibrational frequency in the  $^1\Sigma$  ground state is 57.31  $\text{cm}^{-1}$ , and that in the excited  $^1\Pi$  state is 48.05  $\text{cm}^{-1}$ . The corresponding vals. in the magnetic rotation spectrum of NaRb are 106.6 and 61.5  $\text{cm}^{-1}$ . A band system due to RbCs has been identified.

N. M. B.

**Characteristics of the long and short spectral lines. II. Silver, zinc, and iron.** S. DATTA and K. M. CHATTERJEE (Indian J. Physics, 1936, 10, 65—73; cf. A., 1935, 908).—The long and short lines of Ag, Zn, and Fe have been classified. The fundamental generalisation previously given, with regard to the relative changes in orientation of the  $L$  and  $S$  vectors in the initial and final states for the long and short lines, appears to be verified. M. S. B.

**Regularities in the spectrum of trebly ionised iodine.** S. G. KRISHNAMURTI (Proc. Physical Soc., 1936, 48, 277—281).—The spectrum of a condensed discharge through I has been photographed in the range 6000—1900 Å. under varying conditions of excitation. Data for 68 lines ascribed to I IV and classifications of 34 lines are tabulated. Term vals. and assignments are given on analogy with the isoelectronic spectra Te III, Sb II, and Sn I.

N. M. B.

**Extinction coefficients of iodine and other halogens.** E. RABINOWITCH and W. C. WOOD (Trans. Faraday Soc., 1936, 32, 540—546; cf. A., 1935, 586).—Extinction coeffs. of I vapour, measured at 20° in the range  $\lambda$  4300—6200 Å., are 2—6 times > the accepted vals. Small humps on the extinction curves, appearing both in vapour and solutions, are due to absorption by vibrating mols. The "limiting" extinction curve, obtained by diluting the vapour to a very low partial pressure with an inert gas, has a max. at 5200 Å., and resembles in shape the curve of a  $\text{CS}_2$  solution. The influence of the solvent on the extinction curves of solutions of  $\text{Cl}_2$ , Br, and I is investigated.

F. L. U.

**Band system of caesium.** P. KUSCH and F. W. LOOMIS (Physical Rev., 1936, [ii], 49, 217—218; cf. A., 1934, 1148).—A provisional analysis of the complex system at 6250 Å. is reported.

N. M. B.

**Magnetic moment of caesium determined from the hyperfine structure of the  $6p^2P_1$  state.** L. P. GRANATH and R. K. STRANATHAN (Physical Rev., 1934, [ii], 46, 317).—A  $g$  val. of 0.70 is obtained for Cs.

L. S. T.

**Spark spectrum of mercury, Hg II and Hg III.** T. S. SUBBARAYA (J. Mysore Univ., 1934, 7, 100—134; cf. A., 1934, 1280; 1935, 3).—Additional lines are classified. The ionisation potentials of Hg I and Hg II are 18.67 and 26.1 volts, respectively.

CH. ABS. (e)

**Second spark spectrum of mercury.** R. RICARD (Compt. rend., 1935, 201, 1342—1344).—30 new terms belonging to the Hg III spectrum have been identified in the visible and ultra-violet spectrum excited with an electrodeless discharge.

T. G. P.

**Anomalous Zeeman effect of single hyperfine structure components of the mercury resonance**

**line 2537 Å. II. The  $\sigma$  components.** A. ZVIRONAS (Helv. phys. Acta, 1934, 7, 684—708; Chem. Zentr., 1935, i, 3516; cf. A., 1935, 3).

H. J. E.

**Influence of pressure on the discharge-radiation in mercury vapour.** V. FABRIKANT, F. BUTAEVA, and J. CIRG (Compt. rend. Acad. Sci. U.R.S.S., 1935, 4, 183—184; cf. A., 1934, 1280).—Absorption in Hg discharge at low pressures has been studied.

R. S.

**Fraunhofer's spectrum in the neighbourhood of 96,000 Å.** A. ADEL, V. M. SLIPHER, and O. FOUTS (Physical Rev., 1936, [ii], 49, 288—290; cf. A., 1935, 806).—The absorption of solar radiation by the atm. of the sun and earth, examined in the range 70,000—110,000 Å., is discussed in the vicinity of 96,000 Å. Fine-structure data for the  $\text{O}_3$  band with centre at 1043.7  $\text{cm}^{-1}$  are given, and the structure of the mol. is discussed.

N. M. B.

**Resistance to electric discharge in gas mixtures.** G. M. KOVALENKO (Compt. rend. Acad. Sci. U.R.S.S., 1936, 1, 15—17).—The breakdown potential ( $V$ ) for spherical electrodes at various distances apart in mixtures of  $\text{NH}_3$  and  $\text{N}_2$  at approx. 1 atm. decreases with increasing % of  $\text{NH}_3$  to a min. at approx. 30%  $\text{NH}_3$ . With mixtures of  $\text{Et}_2\text{O}$  and  $\text{N}_2$  a min. occurs at 30%  $\text{Et}_2\text{O}$ . Since  $V$  for pure  $\text{Et}_2\text{O}$  and  $\text{NH}_3$  is >  $V$  for  $\text{N}_2$ , the decrease in  $V$  on adding  $\text{NH}_3$  and  $\text{Et}_2\text{O}$  to  $\text{N}_2$  is attributed to chemical action. With  $\text{NH}_3$   $V$  decreases at each discharge with successive discharges (ultimately becoming const.) owing to the formation of  $\text{H}_2$ , the presence of which in  $\text{N}_2$  at a total pressure of 100 mm. is shown to decrease  $V$ .

R. S. B.

**Electric discharge in gases and the Debye-Hückel theory.** V. T. CHIPLENKAR (Current Sci., 1936, 4, 481).—The Debye-Hückel electrolytic theory is applied to the phenomena in discharge tubes. In approx. agreement with experiment the length of the cathode fall is shown to vary as the log of the p.d. across it.

R. S. B.

**Ionisation steps and excitation energies of spectral lines according to the emission distribution in the arc light.** H. STEPHAN (Z. wiss. Phot., 1936, 35, 33—69).—The intensity of spark lines immediately in front of the cathode is dependent on cathode temp. The increase of intensity of arc lines just in front of the poles is due to higher v.d. The best conditions for observation of ionisation steps are obtained by the use of the smallest possible current through the arc. The arc and spark spectra of Mg, Ca, Cu, and Zn were separated by examining the emission distribution of arcs. The cause of the pole effect with arc lines (displacement of  $\lambda\lambda$  in the neighbourhood of the poles) is probably due to increased v.d.

A. J. M.

**Arcs in rare gases.** R. C. MASON (Physical Rev., 1934, [ii], 46, 630).

L. S. T.

**Determination of the temperature in the column of a discharge from the intensity measurement of rotational band spectra.** T. HAMADA (Proc. K. Akad. Wetensch. Amsterdam, 1936, 39, 50—57; cf. A., 1928, 930).—The radial

temp. distribution in a special  $N_2$  discharge tube of known volt-amp. characteristics has been studied by determination of the intensity of spectral lines. The axial (max.) temp. varies linearly with the product of pressure and current. R. S.

Effect of evaporated films on energy distribution in grating spectra. J. STRONG (Physical Rev., 1936, [ii], 49, 291—296).—Wood anomalies of intensity distribution can frequently be developed by coating the grating, especially if of fine ruling, with an evaporated film of Mg, Ag, or Al. The phenomenon is shown typically by a double band consisting of a dark band on the red side of a bright band; the dark band is characterised by a sharp boundary on the blue side, agreeing with the Rayleigh formula. N. M. B.

Ultra-rapid spectrograph at the Pic du Midi. H. GARRIGUE (Compt. rend., 1936, 202, 44—45).—An instrument operating at  $f$  0.55 is described. H. J. E.

Photographic method for determining the distribution of light intensity in interference rings. J. ROIG (Compt. rend., 1935, 201, 1346—1348). T. G. P.

Fixing scale of Röntgen wave-lengths in absolute measure. M. SÖDERMAN (Nova Acta Soc. Sci. Upsaliensis, 1935, [iv], 9, No. 8; Chem. Zentr., 1935, i, 2942—2943).—The  $\lambda$  of the Al K lines in the 9th and 10th orders are compared directly by a combination of the plane and concave grating methods with the Al spark lines at 50—90 Å., giving 1000 X (exp.) = 1.00212—1.00225 Å. The calcite lattice spacing is recalcd., and  $e$  calc. as  $4.806 \pm 0.003$  c.s.u. J. S. A.

Accuracy of determination of emission and absorption of monochromatic X-rays. H. KÜSTNER and E. ARENDS (Ann. Physik, 1936, [v], 25, 385—412).—An examination of the accuracy of methods previously employed (A., 1935, 556, 676). A. J. M.

Theory of X-ray absorption by molecular gases. III. H. PETERSEN (Z. Physik, 1936, 98, 569—575; cf. A., 1933, 332).—Calculations involved in Kronig's theory are simplified; applied to  $GeCl_4$  they agree with experiment. A. B. D. C.

Polarisation of X-rays from thin targets. D. S. PISTON (Physical Rev., 1936, [ii], 49, 275—279).—The polarisation of the portion of the continuous X-ray spectrum between the K limits of Ta and W, measured for targets of Al foil (0.7  $\mu$ ) and Ag foil (0.17  $\mu$ ), at voltages from the quantum limit up to 120 kv., is complete at the quantum limit, and decreases, more rapidly for Ag than for Al, as the tube voltage is raised above the quantum voltage for the spectrum band. N. M. B.

Wave-length measurements in the K-series of aluminium, sulphur, and chlorine, and in the L-series of zinc. J. SHEARER (Phil. Mag., 1936, [vii], 21, 501—505).—Vals. are tabulated for 9 lines arising from impurities in Ni during investigations previously reported (cf. A., 1935, 1293). N. M. B.

Ruled-grating wave-length of the copper  $K\alpha_1$  line. P. F. GOTTLING and J. A. BEARDEN (Physical Rev., 1934, [ii], 46, 435—436). L. S. T.

K spectrum of copper. Y. CAUCHOIS (Compt. rend., 1935, 201, 1359—1361).—Data for the K $\beta$  regions are recorded and discussed. T. G. P.

K radiation of elements from chromium to copper. M. PRIVAULT (Ann. Physique, 1936, [xi], 5, 280—324).—Three new lines in the K $\beta$  spectra are recorded. The effect of magnetisation of the anticathode on the K $\beta$  spectrum of Fe has been examined. Magnetisation to 75% saturation has no observable effect on the K $\beta_1$  and K $\beta_2$  lines. Temp. changes in the neighbourhood of the Curie and  $\gamma$  points are similarly without effect (for K $\beta_1$  and K $\beta_2$ ). The effect of combination on the K spectra has been examined by a fluorescence method.  $K_2Cr_2O_7$ ,  $MnO_2$ , and  $Fe_2O_3$  show a more general splitting of the lines than recorded by Yoshida (A., 1933, 656). L. J. J.

K spectra of molybdenum and rhodium. H. HULUBEI (Compt. rend., 1935, 201, 1356—1359; cf. A., 1935, 811).—Data for the K $\beta$  spectra are recorded and discussed. T. G. P.

Effects of chemical combination on the L absorption limits of tantalum, tungsten, gold, and lead. S. KAWATA (Proc. Phys.-Math. Soc. Japan, 1935, 17, 89—99).—The shifts of the  $L_{III}$  limits are (in volts):  $HTaO_3 + 2.0$ ;  $H_2WO_4 + 3.0$ ,  $Au_2O - 4.6$ ,  $Au_2O_3 - 3.4$ ;  $PbO + 3.4$ ,  $PbO_2 + 6.8$ . The assumption of a selection rule for X-ray absorption spectra is supported. The Au  $L_{III}$  absorption edge is double in  $Au_2O_3$ . CH. ABS. (c)

Probability of KL ionisation and X-ray satellites. R. D. RICHTMYER (Physical Rev., 1936, [ii], 49, 1—8).—A theory of multiple ionisation produced by a fast-cathode electron in the target of an X-ray tube is developed. The effective cross-section for  $1s2s$  ionisation of K, the distribution of energy and angular momentum, and the probability of  $1s2p$  ionisation are examined. N. M. B.

Ionisation potentials of the  $N_2$  molecule. J. SAVARD (Rev. Fac. Sci. Univ. Istanbul, 1936, 1, 1—7).—Using the method of electronic impact, 11 potentials in good agreement with calc. vals. are reported and the corresponding transformations are given. N. M. B.

Calculation of work of exit in the Richardson effect by a method of O. Scherzer. A. SOMMERFELD [with E. BARTELINK] (Helv. phys. Acta, 1934, 7, Suppl. II, 31—32; Chem. Zentr., 1935, i, 2953).—Theoretical. An expression is derived connecting the work of exit with the at. vol., which agrees with experimental data for the alkali metals. J. S. A.

Calculation of Townsend's  $\alpha$  for neon. M. J. DRUYVESTEYN (Physica, 1936, 3, 65—74).—Theoretical. The velocity distribution of electrons diffusing through an inert gas is calc., assuming elastic, exciting, and ionising collisions. Calc. and observed vals. of the ionisation coeff.  $\alpha$  agree for potential gradients of 5—30 volts per cm. per mm. gas pressure. L. J. J.

**Electrons and positrons.** C. H. DIX (Physical Rev., 1934, [ii], 46, 329—330).—Theoretical.

L. S. T.

**Production of positrons by  $\beta$ -rays.** D. SKO-BELTZYN and E. STEPANOVA (Nature, 1936, 137, 272; cf. A., 1935, 425).—Further evidence of the production of electron-positron pairs by the passage of fast  $\beta$ -rays through Pb and Al is presented. With Al, the predominating effect is the emission of a single positron accompanying the absorption of the primary  $\beta$ -particle. Production of positrons along the track of the  $\beta$ -particle in the gas ( $N_2$ ) was also confirmed. The effective cross-section in  $N_2$  is of the order  $5 \times 10^{-24}$  sq. cm.

L. S. T.

**Positron emission accompanying  $\beta$ -ray activity.** C. MÖLLER (Nature, 1936, 137, 314).—Theoretical.

L. S. T.

**Emission of positrons by a source of Th-B + C.** S. DE BENEDETTI (Compt. rend., 1936, 202, 50—52).—Counts of the positron emission are recorded, using Cellophane and Al screens of varying thickness.

H. J. E.

**Production of electron pairs.** J. C. JAEGER and H. R. HULME (Proc. Roy. Soc., 1936, A, 153, 443—447).—Mathematical. A method, which avoids the use of the Born approximation, for finding the no. of electron pairs created by a  $\gamma$ -ray traversing matter is described. The results are somewhat  $>$  those of Bethe and Heitler (A., 1934, 1150), but it is found that even for heavy elements the Born approximation may be expected to give good results for  $\gamma$ -rays of high energy.

L. L. B.

**Thomson's theory of condensation on ions.** E. HÜCKEL (Physikal. Z., 1936, 37, 137—138).—The assumption made by Thomson, that the charge of the drop is uniformly distributed over the surface of a sphere, does not hold in the case of single ions or electrons, where the charge is rather conc. at the centre of the sphere. An equation is derived on this assumption.

A. J. M.

**Emission of positive ions by platinum when heated in oxygen.** T. B. RYMER (Proc. Roy. Soc., 1936, A, 153, 422—442).—The variation with temp. of the positive ion emission from Pt heated in  $O_2$  has been examined, and the results are discussed in the light of the Saha equation. Satisfactory agreement with the theory is obtained, but a different val. from that determined experimentally must be assumed for the electronic work function, on account of the discontinuous nature of the emitting surface.

L. L. B.

**Absorption of high-energy protons by matter.** J. SOLOMON (Compt. rend., 1936, 202, 204—206).—The energy lost by protons and electrons by radiation and ionisation is considered theoretically.

T. G. P.

**Scattering of high-energy protons in hydrogen.** M. G. WHITE (Physical Rev., 1936, [ii], 49, 309—316).—Comparison of scattering frequency from 7340 photographs of high-energy proton tracks in  $H_2$  with Mott's wave-mechanical treatment showed strong anomalies for incident proton energies  $>$  600 kv. Since Mott assumes coulomb forces, the dis-

crepancies indicate a departure from the inverse square law for such energies. For a classical distance, therefore, of closest approach of about  $6 \times 10^{-13}$  cm. the two protons cannot be treated as point charges, but on classical grounds this is not so down to  $10^{-16}$  cm.

N. M. B.

**Formation of negative atomic ions of mercury.** F. L. ARNOT and J. C. MILLIGAN (Nature, 1936, 137, 150).—By means of the mass spectrograph negatively charged atoms but not negatively charged mols. of Hg have been detected. Their energies are  $>$  can be accounted for by the total potential across the tube or by the dissociation of excited mols.

L. S. T.

**Production of high-velocity particles in a cyclotron by the use of multiphase oscillators.** R. J. MOON and W. D. HARKINS (Physical Rev., 1936, [ii], 49, 273).

N. M. B.

**At. wt. of element 93.** H. J. WALKER (Phil. Mag., 1936, [vii], 21, 262—265).—By analogy with the relations between the isotopes of Ru, Rh, and Pd and between those of Th, Pa, and U, it is suggested that the  $\alpha$ -radioactive isotope of element 93 (eka-Re) has a mass no. 237. The mass nos. of the  $\alpha$ -radioactive isotopes of U and eka-Os are probably U, 232, 233, 234, 235, 236, and 238; eka-Os, 238, 239, 240, 241, 242, and 244. The lighter isotopes of eka-Os are probably short-lived, but eka-Os<sup>241</sup> is probably of long life and may exist terrestrially.

R. S. B.

**Masses of some light atoms measured by means of a new mass spectrograph.** F. W. ASTON (Nature, 1936, 137, 357—358).—Observations on the doublets linking H, D, He, C, and O give the following as the most probable vals. of the isotopic wts. on the physical scale: H  $1.00812 \pm 0.00004$ , D  $2.01471 \pm 0.00007$ , He  $4.00391 \pm 0.00016$ , and C  $12.0035 \pm 0.0003$ .

L. S. T.

**Abundance ratio of isotopes of potassium in mineral and plant sources.** A. K. BREWER (J. Amer. Chem. Soc., 1936, 58, 365—370).—Mass-spectrographic data for a large no. of K-containing minerals show only small differences in the isotope content. The ratio  $K^{39}/K^{41}$  is about 14.25. Greater variation is found in plant ashes, the  $K^{41}$  content differing by as much as 15%. Kelp shows a pronounced deviation from the average. The ratio varies with the variety, age, and section of the plant, and the type of soil.

E. S. H.

**Mass-spectrographic determination of the constancy of the at. wt. of potassium in ocean water.** A. K. BREWER (J. Amer. Chem. Soc., 1936, 58, 370—372).—The abundance ratio  $K^{39}/K^{41}$  for Pacific Ocean  $H_2O$  is 14.20 for samples obtained from different localities and at depths down to 2500 m. Variations in at. wt. are  $< \pm 0.00026$ . The derived at. wt. of K is 39.094.

E. S. H.

**Isotopic abundance ratios of carbon, nitrogen, argon, neon, and helium.** A. L. VAUGHAN, J. H. WILLIAMS, and J. T. TATE (Physical Rev., 1934, [ii], 46, 327).—Relative intensities of the peaks of mass-spectrograph curves give the following abundance ratios with the average deviations indicated:

$\text{C}^{12} : \text{C}^{13}$  91.6 (2.2),  $\text{N}^{14} : \text{N}^{15}$  265 (8),  $\text{A}^{40} : \text{A}^{36}$  304 (12),  $\text{Ne}^{20} : \text{Ne}^{21}$  337 (20),  $\text{Ne}^{20} : \text{Ne}^{22}$  9.25 (0.08), and  $\text{He}^4 : \text{He}^3 < 35,000$ .  
L. S. T.

**Isotopic constitution of rubidium, zinc, and argon.** A. O. NIER (Physical Rev., 1936, [ii], 49, 272).—The abundance ratio  $\text{Rb}^{85}/\text{Rb}^{87}$  is  $2.68 \pm 0.02$ . The upper limits of abundance relative to  $\text{Rb}^{85}$  computed for undetected hypothetical isotopes are,  $\text{Rb}^{80}$ , 81, 82, 89, 90,  $1 \times 10^{-5}$ ;  $\text{Rb}^{83}$ ,  $1/60,000$ ;  $\text{Rb}^{84}$ ,  $1/12,000$ ;  $\text{Rb}^{86}$ ,  $1/13,000$ ;  $\text{Rb}^{88}$ ,  $1/22,000$ .  $\text{Zn}^{61}$ , 66, 68, 67, 70 were found. The upper abundance limits relative to  $\text{Zn}^{70}$  of  $\text{Zn}^{65}$ , 63, 69 are  $1/200$ ,  $1/400$ , and  $1/300$ , respectively.  $\text{A}^{38}$  was confirmed.  $\text{A}^{40}/\text{A}^{36} = 325$ , and  $\text{A}^{36}/\text{A}^{38} = 5.1$ . The upper abundance limits of hypothetical isotopes relative to  $\text{A}^{40}$  are  $\text{A}^{41}$ ,  $39$   $1 \times 10^{-4}$ , and  $\text{A}^{42}$ ,  $37$   $0.5 \times 10^{-4}$ .  
N. M. B.

**Mass ratios of isotopes from band spectra.** W. W. WATSON (Physical Rev., 1934, [ii], 46, 319).—The effect of the perturbing interactions between the various energy states of a mol. on the  $B$  consts. should always be investigated in obtaining accurate mass ratios from band spectra. The corrections to be applied in the case of  $\text{CaH}$  and  $\text{CaD}$  are discussed.  
L. S. T.

**Chemical elements and natural atomic types from the viewpoint of the investigation of isotopes.** O. HAHN (Ber., 1936, 69, [A], 5—20).—A review of work published between the end of 1934 and of 1935.  
H. W.

**Properties of ions. I. Electronic homologues in the periodic system. II. Periodic system and the properties of ions.** B. V. NEKRASSOV (Bull. Soc. chim., 1936, [v], 3, 151—155, 155—159).—I. A new presentation of the periodic system, based on the electronic structures of the elements in their different states of valency, is given.

II. The properties of ions are discussed in the light of the above classification.  
E. S. H.

**System of masses of light atoms deduced from nuclear reactions alone. II.** L. ISAKOV (Compt. rend. Acad. Sci. U.R.S.S., 1935, 4, 141—143; cf. this vol., 7).—Using the data of nuclear reactions, the at. wts. of the light elements up to Si have been determined and are compared with "chemical" and "physical" at. wts. When deviations of the at. mass vals. from the nearest integer val. are plotted against at. nos. between H and Al the curve is wave-shaped, the amplitudes of the waves rapidly diminishing until ultimately a straight line is obtained.  
W. R. A.

**Some properties of radioactive series.** E. LOPOUKHIN (Compt. rend., 1935, 201, 1361—1363).—The different phases of radioactive disintegration are discussed from the point of view of Perrin's nuclear model (A., 1932, 556).  
T. G. P.

**Continuous spectra of Ra-E and Ra-P<sup>30</sup>.** A. I. ALICHANOV, A. I. ALICHANIAN, and B. S. DZELEPOV (Nature, 1936, 137, 314—315).—The energy distribution curve of  $\beta$ -particles from Ra-E reveals the emission of a large no. of electrons with low energies. Comparison with the  $\beta$ -spectrum of radio-P, which has a max., shows a considerable

difference in the shape of the  $\beta$ -spectra of elements of low and high at. no.  
L. S. T.

**Absence of low-energy radiations from potassium and rubidium.** W. F. LIBBY (Physical Rev., 1934, [ii], 46, 745—746).—Geiger-Müller counter experiments indicate that no  $\alpha$ -particle of range much  $> 0.05$  cm. or  $\beta$ -particle with energy much  $> 500$  e.v. is emitted by K. The emission of any preliminary radiation is improbable. With Rb it is even less likely that a low-energy  $\alpha$ - or  $\beta$ -particle is initially emitted.  
L. S. T.

**Evidence of an excited state in the  $\alpha$ -particle.** C. C. LAURITSEN and H. R. CRANE (Physical Rev., 1934, [ii], 46, 537—538).—The 12 m.e.v.  $\gamma$ -ray component observed when Li is bombarded with protons (this vol., 402) is ascribed to the process  ${}^3\text{Li}^7 + {}^1\text{H}^1 \rightarrow {}^2\text{He}^4$ , in which the product of the reaction is presumably the only possible source of the  $\gamma$ -radiation. Analogous cases in which a  $\gamma$ -ray appears to be associated with an excitation level in one of the final products of the reaction are discussed.  
L. S. T.

**Does the  $\alpha$ -particle possess excited states?** E. FEENBERG (Physical Rev., 1936, [ii], 49, 328—331).—Evidence from recent experiments (cf. Crane, A., 1935, 1186) is supported by computations on three different nuclear models which indicate definitely a singlet  $2p$  level in the discrete eigenvalue spectrum of the  $\alpha$ -particle if the range of the intra-nuclear forces exceeds  $2.0 \times 10^{-13}$  cm.  
N. M. B.

**$\alpha$ -Particles from lithium ions striking hydrocarbon compounds.** J. ZELENY, C. J. BRASEFIELD, C. D. BOCK, and E. C. POLLARD (Physical Rev., 1934, [ii], 46, 318).—Bombardment of  $\text{NH}_4\text{Cl}$  and  $\text{Al}(\text{OH})_3$  with  $24 \times 10^4$  volt Li ions yields a small no. of  $\alpha$ -particles (approx. 12 and 9 per min. per microamp., respectively) resulting from the disintegration of Li, probably  $\text{Li}^7$ .  
L. S. T.

**Ranges of  $\alpha$ -particles in photographic emulsions.** H. J. TAYLOR and V. D. DABHOLKAR (Proc. Physical Soc., 1936, 48, 285—298; cf. A., 1935, 910).—From measurements on Ilford  $R$  plates of the tracks of a homogeneous group of  $\alpha$ -particles of range  $r$ , a distribution curve is drawn, from which  $L$ , the extrapolated length of the tracks, is calc. The ratio  $L/r$  is const.  $\pm 1\%$  for  $\alpha$ -particles of various ranges, and if  $L$  is measured  $r$  can be calc. This method, applied to the tracks produced by the disintegration of B and Li under slow-neutron bombardment, gives ranges  $1.14 \pm 0.02$  and  $6.64 \pm 0.06$  cm., respectively, in air. Sm emits  $\alpha$ -particles of range  $1.13 \pm 0.02$  cm. in air, and other particles of longer range.  
N. M. B.

**Scattering of fast  $\beta$ -particles by nitrogen nuclei.** F. C. CHAMPION (Proc. Roy. Soc., 1936, A, 153, 353—358).—The scattering of fast  $\beta$ -particles by N nuclei has been examined between  $20^\circ$  and  $180^\circ$ . Over the whole range, the most satisfactory agreement is with Mott's formula (A., 1929, 861). For the large-angle scattering the results support those of Neher (A., 1931, 1347), and for smaller angles those of Chadwick and Mercier (Phil. Mag., 1925, [vi], 50, 208).  
L. L. B.

**Anomalous absorption of  $\beta$ -rays.** D. SKO-BELZYN and (MISS) E. STEPANOVA (Nature, 1936, 137, 234). L. S. T.

**Energy of  $\gamma$ -rays excited by slow neutrons.** S. KIKUCHI, H. AOKI, and K. HUSIMI (Nature, 1936, 137, 186; cf. this vol., 266).—The energy of  $\gamma$ -rays accompanying the recombination of a proton with a slow neutron to form a deuteron is  $2.2 \times 10^6$  e.v. Curves showing the energies of  $\gamma$ -rays excited in Cd, Cl<sub>2</sub>, Cu, and Fe by slow neutrons are given. The  $\gamma$ -rays from Cd have at least two components, whilst those from Cl<sub>2</sub> appear to be homogeneous.

L. S. T.

**Absorption measurements of hard  $\gamma$ -rays from fluorine bombarded by protons.** E. McMILLAN (Physical Rev., 1934, [ii], 46, 325).— $\gamma$ -Rays from various targets bombarded by  $1.1 \times 10^6$  volt-protons and  $2.2 \times 10^6$  volt-deuterons have been investigated. With proton bombardment B, Be, Li, and F give strong  $\gamma$ -rays in increasing order of intensity. The F radiation is homogeneous and no neutrons are indicated. With deuteron bombardment F, C, B, Li, and Be give strong ionisation, part of which is due to neutrons.

L. S. T.

**Absorption of  $\gamma$ -rays excited in cadmium by slow neutrons.** H. HERSZFINKIEL and L. WERTENSTEIN (Nature, 1936, 137, 106–107).—The amount of  $\gamma$ -rays excited in Cd by neutron bombardment is practically independent of the thickness of Cd traversed between 0.1 and 1 mm. and decreases when thicker sheets are used. Further results obtained with screens of Pb, Fe, and Al indicate that the energy of these  $\gamma$ -rays must be of the order of  $10^7$  e.v.

L. S. T.

**$\gamma$ -Rays from boron bombarded with deuterons.** H. R. CRANE, L. A. DELSASSO, W. A. FOWLER, and C. C. LAURITSEN (Physical Rev., 1934, [ii], 46, 1109–1110).—The spectrum of recoil electrons produced by the  $\gamma$ -rays from B bombarded with deuterons consists of components of  $\leq$  five different energies.

L. S. T.

**High-energy  $\gamma$ -rays from lithium and fluorine bombarded with protons.** H. R. CRANE, L. A. DELSASSO, W. A. FOWLER, and C. C. LAURITSEN (Physical Rev., 1934, [ii], 46, 531–533; cf. A., 1935, 1186).

L. S. T.

**Nuclear photo-electric effect in deuterium.** G. ISING and M. HELDE (Nature, 1936, 137, 273).—The val. obtained for the mass of the neutron is 1.0080 (cf. A., 1935, 1293).

L. S. T.

**Existence of resonance levels for the capture of neutrons.** H. VON HALBAN, jun., and P. PREISWERK (Compt. rend., 1936, 202, 133–135).—Resonance levels seem to exist.

T. G. P.

**Energy distribution of neutrons slowed by elastic impacts.** E. U. CONDON and G. BREIT (Physical Rev., 1936, [ii], 49, 229–231).—Mathematical. The energy distribution of particles of mass  $m$ , initially of the same energy, which have made  $n$  impacts with particles of mass  $M$ , all initially at rest, is calc.

N. M. B.

**Effect of scattering neutrons on induced radioactivity.** J. ROTBLAT and M. ZYR (Nature, 1936,

137, 185–186).—The effect of screens or scatterers of various elements on the radioactivity induced in Ag by neutrons has been investigated. The component of 140 sec. half-period is increased in amount by Si, Fe, Cu, Zn, Ag, Cd, Sn, Hg, and Pb, but not by C or Al. The 22 sec. product is enhanced by C, Al, Cu, Cd, and Sn, and weakened by Hg or Ag.

L. S. T.

**Absorption of slow neutrons in carbon.** G. A. FRINK, J. R. DUNNING, and G. B. PEGRAM (Physical Rev., 1936, [ii], 49, 340).—In view of uncertainty as to whether C is responsible for some of the absorption of slow neutrons in paraffin (cf. A., 1935, 1186) data are given for neutrons detected per min. by a Li-lined ion chamber from a Rn-Be source surrounded by a paraffin sphere and a C cylinder. Results indicate that if C absorbs any slow neutrons this is  $>$  compensated for by neutrons slowed down in the C.

N. M. B.

**Capture of slow neutrons.** O. R. FRISCH and G. PLACZEK (Nature, 1936, 137, 357).—Cd is an efficient absorber for neutrons of thermal energies, but becomes almost transparent for neutrons of energy  $\geq$  1 volt. The capture probability in Cd has a max. between 1 and 0.03 volt.

L. S. T.

**Neutrons of thermal energies.** P. B. MOON and J. R. TILLMAN (Proc. Roy. Soc., 1936, A, 153, 476–492).—Experiment shows that a large proportion of the "slow" neutrons formed when fast neutrons pass through H<sub>2</sub>O or paraffin wax have thermal velocities. The cross-sections for the absorption of thermal neutrons by the nuclei Cu, V, Dy, Ag, Rh, I, and B increase when the temp. of the neutrons is reduced from room temp. to 90° abs., the increase depending on the geometrical conditions of the experiment. The apparent absorption of neutrons by I and by Ag is greatest when measured with the same element as detector.

L. L. B.

**Selective absorption of neutrons by gold.** O. R. FRISCH, G. HEVESY, and H. A. C. MCKAY (Nature, 1936, 137, 149–150).—Experiments on the activation of Au by neutrons slowed down by paraffin wax with a Cd filter indicate that there is a group of neutrons of narrow velocity range which are strongly absorbed by Au, but transmitted through Cd. The no. of strongly absorbed neutrons is apparently only a small fraction of the total no. transmitted by Cd.

L. S. T.

**Selective scattering of slow neutrons.** J. R. TILLMAN (Nature, 1936, 137, 107).—The  $\beta$ -ray activity induced in I, Ag, and Cu by neutrons slowed down by paraffin wax is increased by different amounts when the metals are backed with a further layer of paraffin wax.

L. S. T.

**Agreement between the balance of nuclear energy and the experimental masses of light elements.** L. CARTAN (Compt. rend., 1935, 201, 1363–1366).—The mass of the H atom (O=16) has been corr. to  $1.00810 \pm 0.00010$  from a study of the reactions  $B^{11} + H^1 = 3He^4$ ,  $Be^9 + H^1 = Li^6 + He^4$ ,  $B^{10} + D^2 = 3He^4$ , and  $B^{10} + D^2 = B^{11} + H^1$ , and vals. for D, He<sup>4</sup>, Li<sup>6</sup>, Li<sup>7</sup>, Be<sup>9</sup>, B<sup>10</sup>, B<sup>11</sup>, and C<sup>12</sup> calc. which agree with those of Oliphant *et al.* (A., 1935, 910), excepting

those of  $\text{Be}^9$  and  $\text{C}^{12}$ , which are  $9.0152$  and  $12.0037 \pm 0.0010$ , respectively.

T. G. P.

**Disintegration with the emission of protons induced by neutrons.** F. N. D. KURIE (Physical Rev., 1934, [ii], 46, 330).—Disintegration by neutrons from Be bombarded with  $3 \times 10^6$  volt-deuterons in which a proton or other particle of charge approx. 1 is emitted instead of the usual  $\alpha$ -particle is described. Possible reactions are  ${}^7\text{N}^{14} + {}^0n^1 \rightarrow {}^6\text{C}^{11} + {}^1\text{H}^1$  or  ${}^8\text{O}^{16} + {}^0n^1 \rightarrow {}^7\text{N}^{16} + {}^1\text{H}^1$ .

L. S. T.

**Disintegration of nitrogen by neutrons.** T. W. BONNER and W. M. BRUBAKER (Physical Rev., 1936, [ii], 49, 223—229).—Disintegrations observed in a cloud-chamber filled with  $\text{N}_2$  at reduced pressure are attributed to one of the reactions:  ${}^7\text{N}^{14} + {}^0n^1 \rightarrow {}^5\text{B}^{11} + {}^2\text{He}^4$ ;  ${}^7\text{N}^{14} + {}^0n^1 \rightarrow {}^6\text{C}^{14} + {}^1\text{H}^1$ ;  ${}^7\text{N}^{14} + {}^0n^1 \rightarrow {}^2\text{He}^4 + {}^2\text{He}^4 + {}^3\text{Li}^7$ . The first is valid for slow and fast neutrons, the energy of disintegration for the reaction being  $2.33 \pm 0.26$  m.e.v. The second and third reactions are less frequent. Full data for 91 disintegration forks are tabulated.

N. M. B.

**Production of radioactive oxygen.** M. S. LIVINGSTON and E. McMILLAN (Physical Rev., 1934, [ii], 46, 437—438).—Bombardment of Pt and Cu targets by  $2 \times 10^6$  volt deuterons in a modified apparatus (A., 1935, 1441) produces a positron activity of  $126 \pm 5$  sec. half-life in  $\text{N}_2$  but not in  $\text{O}_2$ ,  $\text{H}_2$ , or A. This activity is due to activation of  $\text{N}_2$  (1 atom. per  $10^6$  incident deuterons), probably according to the reactions  ${}^7\text{N}^{14} + {}^1\text{H}^2 \rightarrow {}^8\text{O}^{15} + {}^0n^1$  and  ${}^8\text{O}^{15} \rightarrow {}^7\text{N}^{15} + {}^1e^+$ . The max. energy of the positrons from the second, radioactive process is approx.  $1.7 \times 10^6$  volts.

L. S. T.

**$\beta$ -Ray spectra of some induced radioactive elements resulting from neutron bombardment.** R. NAIDU and R. E. SIDAY (Proc. Physical Soc., 1936, 48, 332—336).—Preliminary determinations are given of the energies of the end-points, found from block diagrams, of the  $\beta$ -ray spectra of some unstable elements produced by neutron bombardment of F, Si, Rh, Ag, Eu, and Dy, a cloud chamber being used.

N. M. B.

**Action of slow neutrons on rare-earth elements.** G. HEVESY and H. LEVI (Nature, 1936, 137, 185).—The decay periods and relative intensities of the artificially radioactive rare-earth elements, as determined by various investigators, are summarised, together with new data for the absorption of slow neutrons by the rare-earth elements. Discrepancies in published data appear to be due mainly to the presence of small amounts of impurities.

L. S. T.

**Cosmic-ray particles of high penetrating power.** L. LEPRINCE-RINGUET (Nature, 1936, 137, 358).—New measurements agree with the assumption that the more penetrating cosmic rays consist of positive and negative electrons and of protons.

L. S. T.

**General interpretation of cosmic-ray effects.** R. A. MILLIKAN (Physical Rev., 1934, [ii], 46, 329; cf. A., 1935, 560).

L. S. T.

**Recovery time of Geiger-Müller counters.** W. E. DANFORTH (Physical Rev., 1934, [ii], 46, 1026—1027).

L. S. T.

**Artificial radioactivity and the conversion of kinetic into  $\gamma$ -ray energy associated with nuclear disintegration by neutrons.** W. D. HARKINS and D. M. GANS (Physical Rev., 1934, [ii], 46, 827—828).—A discussion. The at. nucleus is an efficient converter of large amounts of kinetic into  $\gamma$ -ray energy.

L. S. T.

**Transformation of energy.** (LORD) RUTHERFORD (Nature, 1936, 137, 135—137).—A lecture.

L. S. T.

**Neutron capture and nuclear constitution.** N. BOHR (Nature, 1936, 137, 344—348).—A lecture in which new views are presented.

L. S. T.

**Nuclear stability and isotope shift.** G. BREIT (Physical Rev., 1934, [ii], 46, 319).—Gamow's diagram (A., 1934, 939) is discussed in relation to the observed isotope shifts of Hg and Pb.

L. S. T.

**Neutrino theory of radiation and the emission of  $\beta$ -rays.** R. DE L. KRONIG (Nature, 1936, 137, 149).—A discussion.

L. S. T.

**Does conservation of energy hold in atomic processes?** P. A. M. DIRAC (Nature, 1936, 137, 298—299).

L. S. T.

**Negative protons in the nucleus?** J. H. BARTLETT, jun. (Physical Rev., 1934, [ii], 46, 435; cf. A., 1933, 1226).—Attention is directed to a certain regularity in the isotope pattern which may show how negative protons become incorporated in the nucleus. The case of Zn is discussed. Several elements, including In, Sb, and I, may be found to have 3 odd isotopes.

L. S. T.

**Heights of nuclear potential barriers.** E. D. EASTMAN (Physical Rev., 1934, [ii], 46, 744).—Barrier heights calc. from Heisenberg's theory are compared with other indications of their magnitude.

L. S. T.

**Nuclear moments.** S. FRISCH (Compt. rend. Acad. Sci. U.R.S.S., 1935, 4, 21—22).—The nuclear moments,  $I$ , of elements of odd at. no. are given by  $I = L \pm S$ , where  $L$  is the resultant moment of the proton orbit and the nuclear residue, and  $S$  is the proton spin. Vals. are tabulated.

H. J. E.

**Spin and magnetic moment of the potassium  $\text{K}^{39}$  nucleus.** S. MILLMAN, M. FOX, and I. I. RABI (Physical Rev., 1934, [ii], 46, 320).—Deflexion of a beam of neutral K atoms in a weak magnetic field gives  $3/2$  for the spin of  $\text{K}^{39}$ . The hyperfine structure separation calc. for the  ${}^2\text{S}_1$  normal state is  $0.0147 \text{ cm}^{-1}$ , giving 0.38 unit of the nuclear magneton  $\mu_0/1838$  for the nuclear magnetic moment.

L. S. T.

**Molecular orientation and the probability of excitation and dissociation of the hydrogen molecule by electron impact.** N. SASAKI and T. NAKAO (Proc. Imp. Acad. Tokyo, 1935, 11, 413—415; cf. A., 1935, 1185).—From quantum-mechanical calculations it is deduced that the probability of excitation of the  $\text{H}_2$  mol. to the  $1^3\Sigma$ -state is a max. when the mol. axis is parallel to the electron beam,

in accord with experimental data on the dissociation of  $H_2$  mols. J. W. S.

**Calculation of eigenfunction of metallic electrons.** H. BETHE (Helv. phys. Acta, 1934, 7, Suppl. II, 18—23; Chem. Zentr., 1935, i, 2954).—The method of calculation of Wigner and Seitz (A., 1934, 1283) is applied to the calculation of the eigenfunctions of electrons in metals and in free atoms, and to calculations arising therefrom of cohesion, excited electronic terms, and free electrons in alkali metals. J. S. A.

**Limits of elementary theory of metallic electrons.** L. NORDHEIM (Helv. phys. Acta, 1934, 7, Suppl. II, 3—17; Chem. Zentr., 1935, i, 2954).—The classical theory of Sommerfeld is restated in terms of quantum mechanics, and extended to cover effects at high temp. J. S. A.

**Statistical basis of electron theory of metals.** R. PEIERLS (Helv. phys. Acta, 1934, 7, Suppl. II, 24—30; Chem. Zentr., 1935, i, 2953—2954).—Theoretical. J. S. A.

**Sommerfeld's theory of metals.** K. F. NIESSEN (Ned. Tijdschr. Nat., 1935, 2, 71—89; Chem. Zentr., 1935, i, 3765).—An explanatory résumé of the chief features of the Sommerfeld theory. J. S. A.

**Errors of approximation in Jeffreys' phases.** F. L. ARNOT (Proc. Camb. Phil. Soc., 1936, 32, 161—178).—The errors involved in the use of an approximation method due to Jeffreys of solving the radial wave equation for the motion of an electron in the field of a spherically symmetrical atom are examined with reference to neutral Cl. A. J. M.

**Statistical theory of neutral atoms.** P. LAL and K. LAL (Indian J. Physics, 1936, 10, 1—6).—A simplified method is given for calculating the binding energy of an atom by making use of the Thomas-Fermi statistical model and neglecting the interaction between electrons. For the lighter atoms the results are in good agreement with those derived by other methods. An expression for the radius of a neutral atom has also been obtained. M. S. B.

**Dispersion of light in the region of magnetic dipole lines.** B. MILLANCUK (Bull. Acad. Polonaise, 1935, A, 438—444).—Theoretical. The Kramers-Heisenberg formula for dispersion holds for magnetic dipole lines if the corresponding transition probabilities are substituted. A. J. M.

**Magnetic dipole radiation.** B. MILLANCUK (Bull. Acad. Polonaise, 1935, A, 430—437).—Theoretical. The Zeeman separation and intensity ratios of spectral lines due to magnetic dipole radiation are calc. on Dirac's theory. A. J. M.

**Limit to the quantum theory and the avoidance of negative energy transitions.** H. T. FLINT (Nature, 1936, 137, 313—314).—The principle of min. proper time, according to which intervals of proper time  $< h/m_0c^2$  have no physical significance, eliminates the conception of an electron moving with a high velocity in a strong field of force and sets a boundary to the region to which such a conception may be applied and to the domain where the quantum theory is valid. L. S. T.

**Annihilation of positrons.** J. C. JAEGER and H. R. HULME (Proc. Camb. Phil. Soc., 1936, 32, 158—160).—Theoretical. A. J. M.

**Space quantisation.** I. I. RABI (Physical Rev., 1936, [ii], 49, 324—328).—A discussion of the effect of a rapidly varying weak magnetic field on an oriented atom having nuclear spin shows that on the basis of the Phipps-Frisch modification of the Stern-Gerlach experiment nuclear spin can be measured even when the hyperfine structure separation is very small. N. M. B.

**Interrelationships of  $e$ ,  $h/e$ , and  $e/m$ .** R. T. BIRGE (Nature, 1936, 137, 187).—A crit. survey. The existence of a major discrepancy between the grating val. of  $e$ ,  $(4.8029 \pm 0.0005) \times 10^{-10}$  e.s.u., and that obtained by various methods involving  $e/m$  and  $h/e$ ,  $(4.7824 \pm 0.0015) \times 10^{-10}$  e.s.u., indicates that either the Bohr formula for the Rydberg const. or the method of calculating  $e$  on the assumption of a geometrically perfect calcite crystal is incorrect. L. S. T.

**Intensity distribution in band spectra of diatomic molecules.** W. WEHRLI (Helv. phys. Acta, 1934, 7, 676—683; Chem. Zentr., 1935, i, 3515).—A discussion of anomalous data for GaI and InI (cf. A., 1934, 1286). H. J. E.

**Reversal of a branch in a non-electronic band.** A. ADEL (Physical Rev., 1936, [ii], 49, 340).—Attention is directed to the first recorded instances of this phenomenon. N. M. B.

**Chemical reactivity and light absorption.** N. R. DHAR and P. N. BHARGAVA (Indian J. Physics, 1936, 10, 43—47; cf. A., 1935, 144).—The increase in light absorption of a mixture of undried  $H_2$  and Br, above that of the separate constituents, is not observed when the gases are completely dry and therefore non-reactive. This is in accordance with the view that increased absorption is a measure of the reactivity of the system. M. S. B.

**Sodium resonance radiation and the polymerisation of ethylene.** J. C. JUNGERS and H. S. TAYLOR (J. Chem. Physics, 1936, 4, 94—96).— $C_2H_4$  quenches the resonance radiation of Na vapour between  $130^\circ$  and  $250^\circ$ , but no measurable polymerisation of  $C_2H_4$  takes place, contrary to the behaviour with the resonance radiation of excited Hg and Cd. Above  $250^\circ$ , however, the polymerisation of  $C_2H_4$  is catalysed by Na surfaces with an activation energy of 20 kg.-cal. Reasons for the apparently greater efficiency of thermal activation, as compared with photo-activation, are discussed. M. S. B.

**Spectrum emitted by a potassium bromide crystal under X-rays.** P. W. BURBIDGE and T. G. MOORCRAFT (Nature, 1936, 137, 278).—Bands with centres at 5310, 4520, and 3810 Å. have been photographed. L. S. T.

**Ultra-violet spectrum of ammonia.** II. Rotational structure of some bands in the Schumann region. A. B. F. DUNCAN and G. R. HARRISON (Physical Rev., 1936, [ii], 49, 211—214; cf. A., 1935, 912).—The seven (0, 2)—(0, 8) bands of the second electronic state above the normal, in the range

1620—1450 Å., have been photographed, and their structure is discussed. N. M. B.

**Ammonia bands in the near infra-red.** S. K. CHAKRAVORTI (Indian Phys. Math. J., 1934, 5, 25—33).—The fundamental frequencies of  $\text{NH}_3$  are calc. from wave mechanics, the mol. being regarded as a symmetrical pyramidal top, with N at the apex and H at each corner of the equilateral base. The calc. electric moment is 3.2 times the observed val. CH. ABS. (e)

**Band spectra of LiH, LiD, and NaD.** F. H. CRAWFORD and T. JORGENSEN, jun. (Physical Rev., 1934, [ii], 46, 939; cf. A., 1935, 561). L. S. T.

**Absorption spectrum of magnesium hydride in the ultra-violet.** B. GRUNDSTRÖM (Nature, 1936, 137, 108—109).—The absorption spectrum of  $\text{MgH}$  from Mg heated in  $\text{H}_2$  at  $1400^\circ$  shows, in addition to the band at 2430 Å. (A., 1929, 376), a band in the ultra-violet corresponding with a transition from the ground-level  $^2\Sigma$  to a hitherto unknown activated state in  $\text{MgH}$ . L. S. T.

**Intensities in the 3400 band of phosphorus hydride.** P. NOLAN and F. A. JENKINS (Physical Rev., 1934, [ii], 46, 327).—Line intensities in the rotational structure of the  $^3\Pi$ ,  $^3\Sigma$  band of PH have been measured. L. S. T.

**Absorption spectrum of nitrous oxide in Schumann region.** P. K. SEN-GUPTA (Bull. Acad. Sci. Agra and Oudh, 1934, 3, 197—202; Chem. Zentr., 1935, i, 2945).—Continuous absorption commences at 1850 Å., with a region of transmission between 1700 and 1580 Å. The absorption is attributed to the formation of excited N atoms according to  $\text{N}_2\text{O} + h\nu$  (1850) =  $\text{NO} + \text{N}(^2D)$ ;  $\text{N}_2\text{O} + h\nu$  (1580) =  $\text{NO} + \text{N}(^2P)$ , the calc. excitation potentials agreeing with experiment. J. S. A.

**Doublet separation in the normal state of nitric oxide and its thermodynamic quantities.** E. E. WITMER (Physical Rev., 1934, [ii], 46, 629). L. S. T.

**Pressure broadening in the  $\gamma$ -bands of nitric oxide.** O. R. WULF (Physical Rev., 1934, [ii], 46, 316).—An explanation of this effect is discussed. L. S. T.

**Spectrum of the first discharge through nitrogen peroxide.** L. GRILLET and M. DUFFIEUX (Compt. rend., 1935, 201, 1338—1340).—The emission spectrum of feebly excited  $\text{N}_2\text{O}_4$  streaming rapidly through a discharge tube consists of (a) the phosphorescent spectrum of  $\text{NO}_2$ , (b) O I bands, (c) N I bands, (d) the second positive group of  $\text{N}_2$ , (e) the 3 group of NO; three unknown spectra consisting of (f) a vibration-rotation band at  $5996\text{ cm}^{-1}$ , (g) 17 bands between  $5936$  and  $5227\text{ cm}^{-1}$ , (h) bands between  $5398$  and  $6547\text{ cm}^{-1}$  degraded towards the violet, between  $6405$  and  $6576\text{ cm}^{-1}$  degraded towards the red, and a band with a max. at  $6350\text{ cm}^{-1}$ , and (i) numerous unknown lines in the extreme red and infra-red. T. G. P.

**Quantitative data on the absorption spectrum of nitrogen peroxide.** M. LAMBREY and J. CORBIÈRE (Compt. rend., 1935, 201, 1334—1335; cf. A.,

1930, 1496).—The absorption coeffs. of  $\text{N}_2\text{O}_4$  and  $\text{NO}_2$  in the region  $3200$ — $4105\text{ Å.}$  have been measured. T. G. P.

**Absorption spectra of monoxides of alkaline-earth metals.** P. K. SEN-GUPTA (Bull. Acad. Sci. Agra and Oudh, 1934, 3, 203—208; Chem. Zentr., 1935, i, 2947).—The spectra of  $\text{CaO}$ ,  $\text{BaO}$ , and  $\text{SrO}$  show a limit of continuous absorption, corresponding with dissociation into neutral atoms. J. S. A.

**Absorption spectrum of sulphur trioxide.** E. FAJANS and C. F. GOODEVE (Trans. Faraday Soc., 1936, 32, 511—514).—The absorption spectrum of  $\text{SO}_3$  vapour between  $3000$  and  $2200\text{ Å.}$  consists of weak diffuse bands superimposed on a continuous background. The bands are of an unusual type and consist of flat max., with sharp min. separated by an approx. const. frequency distance =  $430\text{ cm}^{-1}$ . The bands cannot be measured with certainty above  $2500\text{ Å.}$  and are not due to  $\text{SO}_2$ . O. J. W.

**Absorption spectra of the tellurium oxides  $\text{TeO}_2$  and  $\text{TeO}$ .** C. S. PLAW (Compt. rend., 1936, 202, 127—128; cf. this vol., 134).—The absorption spectra of  $\text{TeO}_2$ , and of  $\text{TeO}$  which appears when  $\text{TeO}_2$  vapour is heated above  $1000^\circ$  at low pressures, have been studied. T. G. P.

**Band spectra of the lead halides,  $\text{PbF}$  and  $\text{PbCl}$ .** G. D. ROCHESTER (Proc. Roy. Soc., 1936, A, 153, 407—421).—The emission band spectra of  $\text{PbF}$  and  $\text{PbCl}$  are described. Their similarity to the corresponding spectra of the Bi halides is shown to be a consequence of the identity of the vibrational consts. Popov and Neujmin's analysis of  $\text{PbCl}$  (Physikal. Z., Sovietunion, 1932, 2, 394) is incorrect. No definite evidence of Pb isotope effects is obtained, but large Cl isotope effects are observed. The relations of the vibrational consts. of the Pb halides to those of other heavy mols. are considered. L. L. B.

**Absorption spectra the halides of fifth group elements.** H. TRIVEDI (Bull. Acad. Sci. Agra and Oudh, 1934, 3, 229—238; Chem. Zentr., 1935, i, 2946).—From the absorption spectra of  $\text{SbCl}_5$ ,  $\text{AsBr}_3$ ,  $\text{SbBr}_3$ ,  $\text{PI}_3$ , and  $\text{AsI}_3$  the heats of formation per atom of halogen have been calc. Vals. so found differ from accepted thermochemical data.  $\text{AsI}_3$  and  $\text{SbBr}_3$  show a second region of transmission. J. S. A.

**Absorption spectra of formaldehyde and hydrogen cyanide in the far ultra-violet.** W. C. PRICE (Physical Rev., 1934, [ii], 46, 529; cf. A., 1935, 805).—HCN shows bands extending from  $1450$  to below  $1000\text{ Å.}$  The bands at lower  $\lambda$  probably form an electronic series corresponding with an ionisation potential of HCN at  $14.8$  volts. Two types of absorption are indicated. L. S. T.

**Fluorescence and absorption bands of some derivatives of coumarin.** W. CZAPSKA-NARKIEWICZ (Bull. Acad. Polonaise, 1935, A, 445—447).—The fluorescence and absorption spectra of 7-hydroxy-coumarin-3-carboxylic acid (I), Et 7-hydroxy- (II) and 7:8-dihydroxy-coumarin-3-acetoacetate (III) have been investigated. The fluorescence max. are at  $4596$ ,  $4727$ , and  $4679\text{ Å.}$ , and the absorption max. at  $3300$ ,  $3414$ , and  $4517\text{ Å.}$ , for (I), (II), and (III), respectively. A. J. M.

**Absorption of ultra-violet light by some organic substances.** XL. L. MARCHLEWSKI and B. SKARZYŃSKI (Bull. Acad. Polonaise, 1935, A, 474—478).—The ultra-violet absorption spectrum of PhMe in EtOH solution was investigated. The mol. extinction curve has two max. at 2684 and 2720 Å., respectively. A similar curve was obtained for PhEt (max. at 2683 and 2620 Å., respectively).

A. J. M.

**Ergot alkaloids. Ultra-violet absorption spectra of lysergic acid and related substances.** W. A. JACOBS, L. C. CRAIG, and A. ROTHEN (Science, 1936, 83, 166—167).—Curves obtained for this acid and some of its derivatives are reproduced and discussed.

L. S. T.

**Emission spectra of cholesterol irradiated by sun- and ultra-violet light.** A. H. ROFFO and A. E. ROFFO, jun. (Compt. rend., 1935, 201, 1434—1435).—Emission bands at 353.3 and 357.2 mμ occur.

F. O. H.

**Carotene. X. Comparison of absorption spectra measurements on α- and β-carotene and lycopene.**—See this vol., 460.

**Infra-red absorption band of heavy-water vapour.** W. V. NORRIS, H. J. UNGER, and R. E. HOLMQUIST (Physical Rev., 1936, [ii], 49, 272).—Data for a band at 1.5291 μ are discussed.

N. M. B.

**Vibration-rotation bands of hydrogen fluoride.** E. O. SALANT and D. E. KIRKPATRICK (Physical Rev., 1934, [ii], 46, 318).—15 and 11 lines, respectively, of the (3←0) and (4←0) vibration-rotation bands of HF gas have been photographed at 8790 and 6744 Å.

L. S. T.

**Infra-red absorption spectra of quartz and fused silica from 1 to 7.5 μ. I. Experimental method. II. Results.** D. G. DRUMMOND (Proc. Roy. Soc., 1936, A, 153, 318—327, 328—339).—I. The apparatus is described. Sources of error and the accuracy attainable are discussed. The wave-no. error should be < 5 cm.<sup>-1</sup> throughout the range investigated.

II. Results of absorption measurements on a wide range of thicknesses of fused SiO<sub>2</sub> and quartz (ordinary and extraordinary rays) between 1 and 7.5 μ are given. The methods of calculating absorption coeffs. are indicated.

L. L. B.

**Infra-red absorption spectra of HCl in benzene.** E. K. PLYLER and D. WILLIAMS (Physical Rev., 1936, [ii], 49, 215—217).—Absorption curves are given for the range 2.5—4.2 μ. The C<sub>6</sub>H<sub>6</sub> band at 3.38 μ increased in intensity and shifted to longer λ in the solution; bands in the region 2—3 μ were unchanged. When the ratio of the absorption of the solution to the absorption of the C<sub>6</sub>H<sub>6</sub> is found, there appears a band with centre at about 3.49 μ. The relation of absorption to dipole moment is discussed.

N. M. B.

**Near infra-red absorption spectra of acid and basic solutions.** E. S. BARR and E. K. PLYLER (J. Chem. Physics, 1936, 4, 92—93; cf. A., 1934, 829, 1154).—Infra-red absorption spectra of H<sub>2</sub>O and aq. HCl, HBr, NaOH, KOH, ZnBr<sub>2</sub>, ZnCl<sub>2</sub>, and Na<sub>2</sub>CO<sub>3</sub>

have been measured from 1.5 to 2.5 μ. The hydroxides have bands at 2.30 and 2.45 μ, the acids at 2.30 and 2.55 μ, and the salts at 2.30, 2.45, and 2.55 μ. The band at 2.30 μ is produced by hydration and at 2.45 μ by OH<sup>-</sup>.

M. S. B.

**Residual rays of magnesium oxide.** M. PARODI (Compt. rend., 1936, 202, 302—304).—Born's method of calculation for cubic crystals of the NaCl type is applied to MgO. The calc. λλ were 15.85 and 14.47 μ, corresponding with observed vals. of 15.3 and 14.8 μ, respectively.

H. J. E.

**Infra-red absorption spectra of liquefied gases. Methane.** C. CORIN and J. HERRY (Compt. rend., 1936, 202, 41—44).—Data are recorded for the absorption bands of liquid CH<sub>4</sub> and of its solutions in liquid N<sub>2</sub> (< 1 to 50%). Eleven bands were observed at λλ 0.8—2.7 μ, in positions agreeing with vals. for the gas. The data are compared with those for C<sub>6</sub>H<sub>14</sub>.

H. J. E.

**Effects of isomerism on infra-red absorption spectra.** W. GORDY and D. WILLIAMS (J. Chem. Physics, 1936, 4, 85—87; cf. this vol., 9).—The spectra of MeCN, EtCN, BuCN, PhCN, MeCNS, EtCNS, and their isomerides, and also of PhCNS, have been determined between 1.0 and 6.5 μ. The characteristic CN band near 4.6 μ is shifted to longer λλ by about 0.2 μ for NC, and its intensity is approx. doubled. This shift agrees with chemical data indicating C<sup>+</sup> and hence weaker binding forces in the NC compounds. The corresponding shift for the SCN isomerides is smaller, but the intensity difference is greater. No other bands in these compounds are appreciably modified by isomerism. This is a further indication of a simple type of binding between C and N atoms modified only slightly by associated groups in the mol. In the absorption spectra of aq. HCN there is an intense band at 4.75 μ and one less intense at 4.95 μ probably attributable to a small amount (2—4%) of HNC.

M. S. B.

**Constitution of oximes and their near infra-red absorption spectra.** (MME.) M. FREYMANN and R. FREYMANN (Compt. rend., 1936, 202, 312—314).—The two forms of oximes, CRAr·N·OH (I) and CRAr· $\begin{smallmatrix} \text{NH} \\ \diagup \text{O} \end{smallmatrix}$  (II), proposed by Ramart-Lucas (A., 1933, 159, 1278) are distinguishable by the infra-red absorption bands at 0.96 and 1.04 μ, associated, respectively, with (OH) and (NH). In the oximes from COEt<sub>2</sub>, COMePr, and COMeBu<sup>s</sup> the (OH) infra-red frequency is observed, and form (I) predominates. In the oximes of dimethylbutylacetophenone and dimethyltetralone both the (OH) and (NH) frequencies occur. The intensity of the (OH) band increases with rising temp., showing that at low temp. these oximes are associated.

H. J. E.

**Infra-red absorption spectra of anthracene hydrocarbons.** M. P. LAMBERT and M. J. LE COMTE (Ann. Office nat. Combust. liq., 1934, 9, 979—993; Chem. Zentr., 1935, i, 3532—3533; cf. A., 1933, 113).—The infra-red absorption spectra of anthracene, diethyl-, di-*n*-butyl-, diisobutyl-, diisomyl-, tetrahydro-, hexahydro-, decahydro-, and

perhydro-anthracene are described and discussed; they are quite different from those of the  $C_6H_6$ ,  $C_{10}H_8$ , and phenanthrene series. Infra-red spectra of 3 oil samples are discussed. H. N. R.

**Infra-red absorption spectra of nuclear halogenated hydrocarbons.** J. LECOMTE (Compt. rend., 1935, 201, 1340—1342; cf. A., 1934, 238).—The bands corresponding with the C-halogen linkings in nuclear monosubstituted benzenes and *m*- and *p*-toluenes have been identified. Their relationships with the Raman spectra are discussed. T. G. P.

**Raman spectrum of crystalline ammonium chloride.** F. T. HOLMES (J. Chem. Physics, 1936, 4, 88—90).—A method of growing cylindrical crystals of  $NH_4Cl$  stable at room temp. is described. The vibrational frequencies of this form are 3146, 3041, 2824, 2010, 1768, 1709, and 1407  $cm^{-1}$ , and subsidiary frequencies 3300 and 3232  $cm^{-1}$ . The high-temp. modification has frequencies 3102, 2801, 1931, 1655, and 1400  $cm^{-1}$ . The results indicate that the  $NH_4$  in cryst.  $NH_4Cl$  has not the geometrical structure of a tetrahedron of cubic symmetry unless it is strongly perturbed in a non-geometric sense. M. S. B.

**Acetylene linking frequency in heavy acetylene ( $C_2D_2$ ).** G. GLOCKLER and H. M. DAVIS (Physical Rev., 1934, [ii], 46, 535).—Raman scattering in  $C_2D_2$  at 2 atm. by 4358 Hg line gave one frequency at 1761  $cm^{-1}$ , which is ascribed to the triple linking vibration. L. S. T.

**Raman effect of neutral alkyl sulphates.** L. MÉDARD and R. MARCHAND (Compt. rend., 1936, 202, 320—321).—Data for  $Me_2SO_4$  and  $Et_2SO_4$  are recorded. The characteristic frequencies 391—433, 564, 1142, and 1370  $cm^{-1}$  of  $H_2SO_4$  are observed with small modifications in the spectra of  $Me_2SO_4$  and  $Et_2SO_4$ . The frequency 391—433  $cm^{-1}$  is associated with the  $:S(O)_2$  group. The alkyl sulphates have no frequency corresponding with the 917  $cm^{-1}$  frequency of  $H_2SO_4$ . The former have a strong frequency at approx. 775  $cm^{-1}$  which does not occur in  $H_2SO_4$ . H. J. E.

**Wing accompanying the Rayleigh line in liquid mixtures.** I. S. C. SIKKAR (Indian J. Physics, 1936, 10, 75—82; cf. this vol., 9).—The distribution of intensity in the wing accompanying the Rayleigh line in the Raman spectra of solutions of 40%  $C_6H_6$  in cyclohexane and 20%  $C_6H_6$  in MeOH has been compared with that due to pure  $C_6H_6$ . The results are discussed on the basis of existing theories. Differences in the distribution of intensity between liquid and gaseous  $C_6H_6$  can be explained by assuming that the wing originates partly in the rotational Raman effect and partly in the widening of the Rayleigh line, due to the fluctuation of the internal field caused by non-periodic and abrupt impacts of neighbouring mols. on the scattering centres. M. S. B.

**Comparison of the Raman spectra of  $\Delta^8$ -octen- $\alpha$ -ols and some of their *cis*- and *trans*-derivatives.** (MLLE.) B. GREDY (Compt. rend., 1936, 202, 322—323).—Data are recorded for amylvinylcarbinol, *trans*- $\alpha$ -bromo- $\Delta^8$ -octene, and for the *cis*-

and *trans*-forms of  $\Delta^8$ -octen- $\alpha$ -ol, Me  $\Delta^8$ -octenyl ether, and octyl acetate. H. J. E.

**Raman spectra and constitution of ozonides.** E. BRINER and E. PERROTTET (Arch. Sci. phys. nat., 1935, [v], 17, Suppl., 283—287; cf. A., 1935, 1446).—Raman frequencies of methyleugenol, methylisoeugenol (I), alone and in  $CCl_4$ , methylvanillin, and (I) ozonide in  $CCl_4$  are tabulated. The lines associated with the  $\cdot CH:CHMe$  group disappear on ozonisation and become replaced by lines characteristic of ozonides. R. S.

**Raman spectra in the eugenol and estragol group.** B. SZUSZ and E. PERROTTET (Arch. Sci. phys. nat., 1935, [v], 17, Suppl., 227—230; cf. A., 1935, 807).—The frequencies and intensities of the Raman lines of eugenol, isoeugenol, vanillin, estragol, and natural and synthetic anethole are given. R. S.

**Raman spectra of terpenes and camphors.** S. K. K. JATKAR and R. PADMANABHAN (Indian J. Physics, 1936, 10, 55—63).—Dipentene (I) gives a Raman spectrum showing all the characteristics of limonene (II) with that of another compound having a strong frequency at 1610  $cm^{-1}$ , probably due to  $\alpha$ -terpinene. It is suggested that both (I) and (II) contain mixtures of different amounts of the products of intramol. isomerisation. The shifts 1412—1450  $cm^{-1}$ , in the spectrum of camphor and not of fenchone, are due to the reactive  $\cdot CH_2 \cdot CO \cdot$  group present in the former only. M. S. B.

**Raman spectrum of rubber and related hydrocarbons.** S. D. GEHMAN and H. J. OSTERHOF (J. Amer. Chem. Soc., 1936, 58, 215—218; cf. A., 1935, 1054).—The most intense frequency in the spectra for rubber (I) (using a conc. solution in  $CS_2-CCl_4$ ) and balata (II) is at 1670  $cm^{-1}$  and is considered to be due to the double linking. Comparison of the frequencies for (I) and (II) with those for  $CHMe:CMMe_2$  (III), myrcene (IV), isoprene (V), and limonene shows that the primary linkings in (I) are similar to those in (III), thus supporting the view that (I) consists of a long chain of isopentene units. The differences in the spectra of (I) and (II) are consistent with *cis-trans* isomerism. The spectrum of (IV) is largely a superposition of those of (III) and (V). H. B.

**Raman spectra of quinoline, quinaldine, isoquinoline, and  $\alpha$ - and  $\beta$ -picolines.** S. K. K. JATKAR (Indian J. Physics, 1936, 10, 23—30).—A comparative study of the Raman spectra of the above compounds has been made. The structures are in harmony with the chemical evidence which indicates a variable stability of the  $C_6H_6$  and  $C_5H_5N$  rings according to whether they form fused-ring compounds containing both rings or one kind of ring only. M. S. B.

**Kinetics theory of liquids and diffusion of light.** J. YVON (Compt. rend., 1936, 202, 212—214).—Theoretical. T. G. P.

**Spectral region of the emission of chemical reactions.** R. AUDUBERT (Compt. rend., 1936, 202, 131—133; cf. A., 1933, 764).—With the aid of photon counters the ultra-violet emissions of the following reactions have been studied: (1) NaOH

+HNO<sub>3</sub>, (2) NaOH+H<sub>2</sub>SO<sub>4</sub>, (3) pyrogallol+O<sub>2</sub>, (4) glucose+KMnO<sub>4</sub>, (5) Na<sub>2</sub>S<sub>2</sub>O<sub>4</sub>+O<sub>2</sub>, (6) O<sub>2</sub>+K<sub>2</sub>SO<sub>3</sub>, (7) O<sub>2</sub>+Na<sub>2</sub>SO<sub>3</sub>, (8) Mg-Hg+H<sub>2</sub>O, (9) Na-Hg+H<sub>2</sub>O, (10) Al-Hg+H<sub>2</sub>O, (11) EtOH+H<sub>2</sub>CrO<sub>4</sub>, (12) 2Br+K<sub>2</sub>C<sub>2</sub>O<sub>4</sub>, (13) 2Br+Na<sub>2</sub>C<sub>2</sub>O<sub>4</sub>, (14) 2I+Na<sub>2</sub>C<sub>2</sub>O<sub>4</sub>. Reactions (1)–(3), (5), (8)–(10) are shown by counters with cathodes of Al or CuI, (11)–(14) only by the former, and (4), (6), and (7) only by the latter.

T. G. P.

**Heterogeneity in crystals and phosphorescence.** M. CURIE (Compt. rend., 1935, 201, 1352–1353; cf. A., 1932, 560).—The rôle of impurities is discussed.

T. G. P.

**Fluorescent power and experimental study of fluorescent power as a function of concentration.** J. BOUCHARD (J. Chim. phys., 1936, 33, 51–71).—At const.  $p_H$  the fluorescent power of uranine solutions follows Perrin's law  $\Phi = \Phi_0 e^{-kc}$  ( $c$  = concn.). The const.  $k$ , measured by the light re-emitted in the direction of the exciting ray and laterally, decreases with increasing  $[H^+]$  and for  $p_H$  6–12,  $\log_{10} k \propto p_H$ . The results are related to the degree of ionisation of the fluorescent substance.

J. W. S.

**Becquerel effect and photochemical sensitivity of some fluorescent dyes.** (Mlle.) C. STORA (Compt. rend., 1936, 202, 48–50).—Vals. are recorded for the photo-potentials of uranine, eosin, and erythrosin. They are lowered by hydrosulphides, phenols, amines, or by TiCl<sub>3</sub>. The relation between the photo-potential, the fluorescence, and the effect of oxidising and reducing agents is discussed.

H. J. E.

**Photometric investigation and measurements of spectral intensity distribution of fluorescent screens, especially on irradiation with electron rays.** M. VON ARDENNE (Z. tech. Phys., 1935, 16, 61–67; Chem. Zentr., 1935, i, 3884).—The intensity and spectral distribution of light from a variety of fluorescent materials when excited by 4000 volt-electrons, X-rays, and ultra-violet light are recorded.

J. S. A.

**Connexion between illumination and strength of current in the barrier-layer photo-cell.** E. ELVEGÅRD (Physikal. Z., 1936, 37, 129–133).—An equation is given which expresses the variation of current obtainable from such cells with intensity of illumination, when connected with different external resistances. The equation can be used for the determination of light intensities.

A. J. M.

**Rectifying effect in chrome cast iron.** L. G. HALL (Physical Rev., 1934, [ii], 46, 1109).—Such an effect is described.

L. S. T.

**Molecular theory of the dielectric constant of non-polar liquids.** J. YVON (Compt. rend., 1936, 202, 35–37).—Mathematical.

H. J. E.

**Influence of a magnetic field on the dielectric constants of gaseous and liquid nitrogen and oxygen.** A. C. YOUNG (Canad. J. Res., 1935, 13, A, 111–119).—A balanced resonance method was used with gases and a special bridge with liquids. The only positive result was with gaseous O<sub>2</sub> at 100 atm. and room temp., when there was a change of  $1.1 \times 10^{-6}$  in the dielectric const. This can be accounted for

quantitatively by the increased pressure of the O<sub>2</sub> in the magnetic field.

E. E. A.

**Polarity of nitrogen tetroxide and nitrogen dioxide molecules.** J. W. WILLIAMS, C. H. SCHWINGEL, and C. H. WINNING (J. Amer. Chem. Soc., 1936, 58, 197–203).—The electric moments of NO<sub>2</sub> and N<sub>2</sub>O<sub>4</sub> mols. have been calc. from measurements of dielectric const. of their gaseous equilibrium mixtures at 298–398° abs. and 150–760 mm. The polarity of NO<sub>2</sub> decreases with rising temp., probably due to the passage of the mols. into more symmetrical higher vibrational states. The dipole moment of N<sub>2</sub>O<sub>4</sub> does not differ greatly from zero.

E. S. H.

**Permanent electric moment and structure of phosphorus pentachloride.** P. TRUNEL (Compt. rend., 1936, 202, 37–39).—Simons and Jessop's results are contradicted (A., 1931, 669). PCl<sub>5</sub> has a permanent dipole moment ( $\mu = 0.8$  at 25°) in CCl<sub>4</sub> or CS<sub>2</sub> solution. The mol. is unsymmetrical. The 5 Cl may not be all identical. Alternatively they are not co-planar.

H. J. E.

**Electrical moment of tantalum pentachloride and the structure of the compounds AX<sub>5</sub>.** H. MOUREU (Compt. rend., 1936, 202, 314–316).—TaCl<sub>5</sub> has a permanent moment of 1.2. The formulation of compounds of the type AX<sub>5</sub> is discussed. The formula cannot be symmetrical.

H. J. E.

**Dielectric constants of mercuric halides.** H. BRAUNE and R. LINKE (Z. physikal. Chem., 1935, B, 31, 12–17).—Measurements of the dielectric const. of HgI<sub>2</sub>, HgBr<sub>2</sub>, and HgCl<sub>2</sub> vapours at various temp. have shown zero dipole moments. The Hg-halogen linking moments are only  $\frac{1}{4}$ – $\frac{1}{3}$  of the val. corresponding with an ideal heteropolar linking.

R. C.

**Magnetic changes [ $\Delta\epsilon$ ] of the dielectric constant of liquids in a field of 20.4 k.-gauss.** A. PIEKARA (Compt. rend., 1936, 202, 206–207; cf. A., 1935, 1192).— $\Delta\epsilon$  has been measured for hexane, CS<sub>2</sub>, C<sub>6</sub>H<sub>6</sub>, and PhNO<sub>2</sub>, but no appreciable change was detected.

T. G. P.

**Polar properties of hydrogenation products of naphthalene.** M. PUCHALIK (Acta phys. polon., 1933, 2, 305–310; Chem. Zentr., 1935, i, 3914).—The following moments are recorded (in C<sub>6</sub>H<sub>6</sub> solution): *cis*- and *trans*-deca-, 0; tetra-hydronaphthalene,  $1.66 \times 10^{-18}$  e.s.u. The finite moment of the last is due to its unsymmetrical structure.

H. N. R.

**Dielectric polarisation of concentrated solutions.** A. JAGIELSKI and J. WESOŁOWSKI (Bull. Acad. Polonaise, 1935, A, 260–269).—Dipole moments of *o*-NO<sub>2</sub>·C<sub>6</sub>H<sub>4</sub>·NH<sub>2</sub>, *o*-C<sub>6</sub>H<sub>4</sub>Me·NO<sub>2</sub>, *o*- and *p*-C<sub>6</sub>H<sub>4</sub>Cl·NO<sub>2</sub>, and Et<sub>2</sub>O, determined in C<sub>6</sub>H<sub>6</sub> solution, are 4.01, 4.22, 4.82, 3.12, and 0.74 ( $\times 10^{-18}$ ) e.s.u., respectively. The vals. differ from those recorded by other workers.

T. G. P.

**Dielectric polarisation.** XIV. Dipole moments of ethyl-, phenyl-, and  $\alpha$ - and  $\beta$ -naphthyl-carbimides. XV. Dipole moments of five-membered nitrogen ring compounds: indole, skatole, carbazole, isatin, phthalimide, and succinimide. E. G. COWLEY and J. R. PART-

INGTON. XVI. Dipole moments of some acid halides and of phosphorus oxychloride. G. T. O. MARTIN and J. R. PARTINGTON (J.C.S., 1936, 45—47, 47—50, 158—163).—XIV (cf. A., 1935, 916). The dipole moments ( $\mu$ ) in  $D$ , at  $20^\circ$ , in  $C_6H_6$  solution, of ethyl-, phenyl-,  $\alpha$ - and  $\beta$ -naphthylcarbimide are 2.81, 2.28, 2.30, and 2.34, respectively. These vals. agree with those for the corresponding thio-carbimides (A., 1933, 1230), allowing for  $\mu$  for  $:C:S$  being  $>$  for  $:C:O$ , and indicate similar linear structure for the  $:N:C:O$ , in agreement with the Raman spectra (Goubeau, A., 1935, 851). The possibility of resonance between three possible structures is discussed.

XV. Indole and skatole in  $C_6H_6$  at  $20^\circ$  give  $\mu$  2.05 and 2.08, respectively; carbazole, isatin, phthalimide (I), and succinimide (II), in dioxan, give  $\mu$  2.09, 5.72, 2.10, and 1.54, respectively.  $\mu$  for indole is  $>$  for pyrrole (A., 1933, 1230), the change in  $\mu$  being paralleled by the vals. for quinoline and  $C_5H_5N$ . In the case of isatin,  $\mu$  agrees with the diketonic formula. Since  $\mu$  for (II) is  $<$  for (I), the five-membered ring with N and two  $:CO$  must have a large polarising influence on the  $C_6H_4$  ring.

XVI.  $\mu$  for  $AcCl$  (in  $C_6H_6$  at  $20^\circ$ ) is 2.45, and for the series  $EtCOCl$ ,  $Pr^iCOCl$ ,  $Bu^iCOCl$ , and  $Bu^sCOCl$  is const. at 2.61—2.63. The large val. of  $\mu$  for  $AcCl$  (calc. 2.25) may be due to induction in the C-C linking. Vals. for  $AcBr$  (2.43) and  $AcI$  support this view.  $CH_3Cl \cdot COCl$  (in  $C_6H_6$  and  $CS_2$ ) and  $CCl_3 \cdot COCl$  (in  $C_6H_6$ ) give  $\mu$  2.22, 2.06, and 1.19, respectively. Free rotation about the C-C linking does not occur, and the  $\cdot COCl$  moment acts at  $16^\circ$  to the C-C axis. For  $POCl_3$ ,  $\mu$  is 2.40, giving 3.56 for the  $P \rightarrow O$  moment.

L. J. J.

Dielectric loss characteristics of a chlorinated diphenyl. W. JACKSON (Proc. Roy. Soc., 1935, A., 153, 158—166).—A study has been made of the dielectric behaviour of a chlorinated diphenyl from  $-20^\circ$  to  $80^\circ$  over the frequency range  $50$ — $10^7$  cycles per sec. The Debye power factor max. has been followed through this range from  $40^\circ$  to  $-5^\circ$ .

L. L. B.

Application of Debye's theory of polar molecules to solid dielectrics. B. J. O'KANE (Phil. Mag., 1936, [vii], 21, 369—383).—Curves are given for the variation of power factor and permittivity with temp. at const. frequency and with frequency at const. temp. for palmitic, oleic, and stearic acids and mixtures of these. If the expression for the viscosity ratio of liquids at different temp. is applied in the Debye expression for the power factor of a dielectric, in terms of the internal viscosity of the medium in which the dipole is assumed to move, the calc. and experimental power factor-temp. curves agree closely. Results indicate that the Debye theory of liquid dielectrics can be applied to solid dielectrics on the assumption that they possess some property analogous to the macroscopic viscosity of liquids and obeying the same temp. variation rules.

N. M. B.

Refractive index and molecular refraction of hydrogen selenide and deuterium selenide. O. E. FRIVOLD, O. HASSEL, and T. SKJULSTAD (Physikal. Z., 1936, 37, 134—136; cf. A., 1935,

148).—Vals. of  $(n_0 - 1) \times 10^6$  for  $H_2Se$  and  $D_2Se$ , respectively, at pressures about 20 mm. are for  $\lambda$  6562.8 Å., 798.3 and 795.1; for 5893.0 Å., 803.9 and 801.2; for 5460.7 Å., 809.8 and 807.6.

A. J. M.

Measurements of dispersion in the ultra-violet. M. BAYEN (Compt. rend., 1936, 202, 207—209).—A previous arrangement has been improved (Duclaux, J. Physique, 1921, 2, 346). Between 2250 and 5900 Å., for heptane at  $23^\circ$   $n^2 = 1.89729 + 0.8886 \times 10^6/\lambda^2 - 1,195,060$ ; for heptene at  $23^\circ$   $n^2 = 1.92364 + 1.0301 \times 10^6/\lambda^2 - 1,877,300$ ; for heptinene at  $22.5^\circ$   $n^2 = 1.95065 + 1.0556 \times 10^6/\lambda^2 - 1,583,500$ .

T. G. P.

Refractive dispersion of organic compounds. VII. Refractive indices of hexane and the refractivities of hydrogen and carbon. Significance of the dispersion constants. VIII. Isomerides of the formula  $C_4H_8O_2$ : dioxan, ethyl acetate, isobutyric acid, and acetoin. C. B. ALLSOPP and H. F. WILLIS (Proc. Roy. Soc., 1936, A, 153, 379—391, 392—406).—VII. The law of additivity of at. refractivities is discussed in the light of the first of the two fundamental observations on which it is based, viz., the constancy of the increment of mol. refraction in homologous series. The refractivity of a mol. may be expected to be the sum of the refractivities of its constituent atoms (or electrons) only when its refractive dispersion can be represented by an equation containing only one variable term with a characteristic frequency in the Schumann region of the spectrum. Vals. of  $n$  for hexane are recorded at 57  $\mu$  between 6708 and 2450 Å. and the at. refractivities of H and C over the same range are deduced with the help of data previously given for cyclohexane. Characteristic frequencies deduced by means of the Ketteler-Helmholtz equation are subject to errors of the order of 100 Å., and trustworthy vals. can be derived only from the Lorentz-Lorenz equation; the error from experimental inaccuracy is  $< 10$  Å.

VIII. Mol. extinction coeffs., refractive indices, and mol. refractivities over a wide range of visible and ultra-violet  $\lambda$  are recorded for dioxan,  $EtOAc$ ,  $Pr^iCO_2H$ , and  $CH_3AcMe \cdot OH$  (I), and at. refractivities are deduced for ethereal, carbonyl, and hydroxyl O. If allowance be made for the variations in the refractivity of O, according to the manner in which it is linked in the mol., the law for additivity of at. refractivities is valid at all  $\lambda$  for these compounds of which the refractive dispersions can be represented by equations containing only one variable term with a characteristic frequency in the Schumann region of the spectrum. The  $f$ -val. of the ketonic absorption band of (I) is almost identical with that of the corresponding band of cyclohexanone. The partial refractions of the absorption bands of org. mols. are not necessarily  $\propto$  the  $f$ -vals.

L. L. B.

Dispersion. K. F. HERZFELD and (Miss) M. G. MAYER (Physical Rev., 1936, [ii], 49, 332—339).—Mathematical. In interpreting measurements in the infra-red and the absorption of hot gases account must be taken of the fact that the measured absorption is the difference between absorption and forced

emission. For a gas, the paramagnetic part of the susceptibility depends on the frequency in the same way as the electric part, but is determined by the magnetic absorption lines; the diamagnetic part is almost independent of the frequency up to X-ray frequencies. N. M. B.

**Werner complexes. Optical activity and configuration of ions of the type  $MA_3$ .** J. P. MATHIEU (J. Chim. phys., 1936, 33, 78—96).—The optical absorption and rotation of  $[Co en_3]Br_3 \cdot 2H_2O$ ,  $[Rh en_3]I_3 \cdot H_2O$ ,  $[Ir en_3]Br_3 \cdot 2H_2O$ , and  $[Cr en_3]I_3 \cdot H_2O$  are compared with those of  $K_3[Cr(C_2O_4)_3] \cdot H_2O$ ,  $K_3[Rh(C_2O_4)_3] \cdot 2H_2O$ ,  $K_3[Ir(C_2O_4)_3] \cdot 2H_2O$ , and  $K_3[Co(C_2O_4)_3]$ . The oxalates have the higher optical activities, but compounds containing the same metal show close analogies. A parallelism exists between the factor of dissymmetry in the active bands and the chemical stability of the compounds. J. W. S.

**Optical activity dependent on co-ordinated bivalent ruthenium.**—See this vol., 485.

**Theory of optical activity. III. Regular tetrahedron twisted through a small angle about a binary axis.** B. Y. OKE (Proc. Roy. Soc., 1936, A, 153, 339—352; cf. A., 1935, 917).—A system of 4 identical vibrators, mutually interacting, at the corners of a tetrahedron gives 5 characteristic frequencies. If one pair of vibrators is rotated through a small angle about the line of centres, the distorted system becomes optically active. The rotatory power is calc. by a method of approximation; it is  $\propto$  the third power of the small angle of twist. L. L. B.

**Absolute configuration of lactic acid. Assumptions made in calculation of optical rotation.**—See this vol., 454.

**Magnetic rotatory power and dispersion of alkali mercuritetra-iodides.** R. LUCAS and F. GALLAIS (Compt. rend., 1936, 202, 129—131).—The exceptional rotatory properties of  $K_2HgI_4$ , which have been measured, are due to a broad absorption band. T. G. P.

**Electrical birefringence of compressed nitrogen.** H. BIZETTE (Compt. rend., 1936, 202, 304—305).—Measurements were made at 150 kg. per sq. cm. and with a field of 160,000 volts per cm. The val. of the Kerr const. found was approx. half that given by Bruce and Breazeale (cf. A., 1933, 1232; 1935, 1192). H. J. E.

**Electro-optic effect in zinc blende.** C. SCHRAMM (Ann. Physik, 1936, [v], 25, 309—336).—The double refraction and inhomogeneity of the crystals are due to cutting or polishing. Kerr consts. for Tl, Na, and K light are given and compared with the piezo-electric consts. ZnS has "light" voltage of 1240 or about one third the val. of  $PhNO_2$ . W. R. A.

**Constitution of thioether compounds of platinum. II.** K. A. JENSEN (Z. anorg. Chem., 1936, 226, 168—172).—An explanation of the results of Lifschitz *et al.* (A., 1935, 1335), different from that of the authors, is given. M. S. B.

**Planar configuration of quadricovalent compounds of bivalent copper and nickel.** E. G.

COX, E. SHARRATT, W. WARDLAW, and K. C. WEBSTER (J.C.S., 1936, 129—133).— $Cu(C_5H_5N)_2Cl_2$  (I) has been prepared under various experimental conditions with the object of identifying *cis*- and *trans*-isomerides. Only the *trans*-form was obtained, even by the action of  $C_5H_5N$  on *Cu alkylglyoxime dichlorides*, which must form *cis*-(I) initially. The cell dimensions of *cryst.* (I), determined by X-ray methods (*c*-axis 3.84 Å.), show that it can only have *trans*-planar configuration, in agreement with previous work (A., 1935, 920). *Cu* and *Ni bismethylethylglyoximes* are isomorphous, and occur in one form only. L. J. J.

**Significance of non-localised linkings ("p]-electron cloud") of aromatic hydrocarbons in formation of their molecular compounds with dipolar molecules.** G. BRIEGLEB (Z. physikal. Chem., 1935, B, 31, 58—78).—The secondary valency in the above mol. compounds depends chiefly on a dipole induction of the polar groups of the dipolar mol. on the polarisable charge of the unsaturated hydrocarbon. In mol. compounds of polar mols. with  $C_6H_6$  or condensed ring systems the polar groups of the dipoles induce moments in the localised  $\sigma$ -linkings of the hydrocarbon ( $\sigma$ -polarisation) and also perturb the charge distribution of the non-localised  $[p]$ -electrons ( $[p]$ -electron polarisation) (cf. A., 1932, 901). The induction effect changes the absorption spectrum of the hydrocarbon considerably, which is responsible for the characteristic colour of the mol. compound. Both polarisations can be estimated from spectroscopic data. Calc. heats of formation of compounds of unsaturated ring systems with  $NO_2$ -compounds agree satisfactorily with the observed vals. If a dipolar mol. forms a 1:1 compound with an unsaturated aromatic hydrocarbon with two Ph nuclei linked by saturated or unsaturated hydrocarbon chains, it adds itself to a Ph nucleus and an induction perturbation initially localised at that nucleus may be transmitted by the non-localised  $[p]$ -electrons to the other nucleus. Such spreading of the perturbation is stopped, however, by a  $CH_2$  group. R. C.

**Concepts of "resonance" and "intermediate stages" for organic substances with multiple linkings, and electronic formulæ.** F. ARNDT and B. EISTERT (Z. physikal. Chem., 1935, B, 31, 125—131).—The modern concept of "resonance between two mol. states" is equiv. to the authors' "intermediate stage" theory (A., 1925, i, 57; A., 1935, 324). Modifications in the representation of electronic formulæ are suggested. R. C.

**Formation of mercury molecules.** F. L. ARNOT and J. C. MILLIGAN (Proc. Roy. Soc., 1936, A, 153, 359—378).—Mainly a detailed account of work already noted (A., 1935, 1917). The ionisation potential of the mol. is 9.65 volts. A max. is observed in the mol. ionisation at 11.5 volts, due to triplet excitation, and a second max. at 40 volts, due mainly to singlet excitation of the atom which goes to form the mol. ion. L. L. B.

**Motions exhibited by anisotropic liquids under the influence of an electric field.** V. FREDERICKS and V. TZVETKOV (Compt. rend. Acad. Sci., U.R.S.S., 1935, 4, 131—133).—The motions

of *p*-azoxyanisole in an electric field depend on the field strength and the thickness of the layer of liquid. The mol. axes of the turbulently streaming particles lie parallel to the force lines of the applied field.

W. R. A.

"Gas mists." V. NJEGOVAN (Z. Physik, 1935, 98, 415—416).—Correction of earlier work (this vol., 14).

A. B. D. C.

Association of liquids at the b.p. K. BILLIG (Ber., 1936, 69, [B], 434—436; cf. A., 1935, 815).—Mathematical relationships are developed between the association factor and surface tension at the b.p., sp. cohesion, and elevation of the b.p. by dissolved substances.

H. W.

Pressure effect on predissociation. W. LOCHTE-HOLTGREVEN (Nature, 1936, 137, 187—188).—The dependence of predissociation on pressure is discussed for S.

L. S. T.

Kinetics of dense fluids in two or three dimensions. E. FAHIR (Rev. Fac. Sci. Univ. Istanbul, 1936, 1, 8—13).—Mathematical. The electrostatic potential and field on a mol. partly immersed in an ideal fluid are examined.

N. M. B.

Dissociation of  $\text{SnCl}$  and  $\text{SnCl}_2$ . H. LESSHEIM and R. SAMUEL (Indian J. Physics, 1936, 10, 7—12).—The covalent character of the  $\text{SnCl}$  and  $\text{SnCl}_2$  linkings is reaffirmed (cf. A., 1933, 996; 1934, 477; cf. Trivedi, A., 1935, 913).

M. S. B.

Calculation of linking energies. W. LASAREFF (Physica, 1936, 3, 61—64).—From the dissociation energy of CO, vals. of 108 or 124 kg.-cal. are calc. for the transition  $\text{C}_{\text{diamond}} \rightarrow \text{C} (^3P)_{\text{gas}}$  at  $0^\circ$  abs., giving 51 or 59 kg.-cal., respectively, for the C-C linking in aliphatic hydrocarbons. A correction term to account for the discrepancy with the observed val. ( $> 70$  kg.-cal.) is suggested. Gershinowitz' criticism (A., 1935, 1448) is rejected.

L. J. J.

(A) Calculation of energy of  $\text{H}_3$  molecule. (B) Calculation of energy of  $\text{H}_3^+$  ion. J. HIRSCHFELDER, H. EYRING, and N. ROSEN (J. Chem. Physics, 1936, 4, 121—130, 130—133).—Mathematical.

M. S. B.

Zero point energy in determination of structure of solids. A. R. UBBELOHDE (Trans. Faraday Soc., 1936, 32, 525—529).—Substitution of one isotope for another in a solid compound will lead to differences in vibrational and rotational frequencies which, in certain cases, should be large enough to afford information on the structure of the solid.

F. L. U.

Constants of the methane molecule. T. NEUGEBAUER (Z. Physik, 1936, 98, 638—656).—Assuming the nucleus  $\text{C}^4$  and externally the Ne proper function, the polarisation energy in the inhomogeneous field of the four protons, the C-H separations, and vibration frequencies are calc.

A. B. D. C.

Normal vibration frequencies of the molecule  $\text{XYZ}_3$ . (Miss) J. E. ROSENTHAL and H. H. VOGEL (J. Chem. Physics, 1936, 4, 134—136).—A general expression is derived for the potential energy of the tetrahedral mol.  $\text{XYZ}_3$  and the normal vibration frequencies are given as functions of the consts.

The mode of application of these general formulæ to special types of potential energy functions is indicated.

M. S. B.

Potential functions of molecular groups and the vibrations of the halogen derivatives of methane. H. H. VOGEL and (Miss) J. E. ROSENTHAL (J. Chem. Physics, 1936, 4, 137—143).—Assuming that, in a series of mols.  $\text{YZ}_4$ ,  $\text{XYZ}_3$ ,  $\text{ZYX}_3$ , and  $\text{YX}_4$ , the potential energy of the  $\text{YZ}_3$  is the same whether it is attached to an X or to another Z and the force between Y and X is not changed by the nature of the other atoms in the mol., formulæ connecting the potential energy consts. of these mols. are given. Application to the series  $\text{CH}_4$ ,  $\text{MeCl}$ ,  $\text{CHCl}_3$ , and  $\text{CCl}_4$  gives satisfactory results. Frequencies calc. for  $\text{CHCl}_3$  and  $\text{CDCl}_3$  from those of  $\text{CH}_4$ ,  $\text{MeCl}$ , and  $\text{CCl}_4$  are in good agreement with observed data. Vals. for the frequencies of  $\text{CD}_3\text{Cl}$  are predicted. The  $\text{CH}_4$  consts. are discussed and it is shown that, although individual consts. may vary with the method of determination, certain linear combinations of them, to which a definite physical meaning can be attached, are practically invariant. The  $\text{C}_2\text{H}_6$  consts. calc. from the  $\text{CH}_4$  consts. are entirely different from those given by Sutherland *et al.* (A., 1935, 569), but account equally well for the observed frequencies.

M. S. B.

Dipole attraction and hydrogen bond formation in their relation to solubility. J. H. HILDEBRAND (Science, 1936, 83, 21—24).—An address.

L. S. T.

Rotation of dipoles in elastic and viscous media. N. L. YATES-FISH (Phil. Mag., 1936, [vii], 21, 226—233).—The couple acting on a rigid sphere when this is rotated through a small angle in a medium possessing relaxing elasticity has been calc. The result is applicable to the rotation of a dipole in a solid (cf. this vol., 21).

R. S. B.

Applications of astrophysics to physics and chemistry. W. NERNST (Oesterr. Chem.-Ztg., 1936, 39, 34—36).—A lecture.

Evaporation of small drops and the relationship between surface tension and curvature. J. L. SHERESHEFSKY and (Miss) S. STECKLER (J. Chem. Physics, 1936, 4, 108—115).—Rates of evaporation of  $o\text{-C}_6\text{H}_4(\text{CO}_2\text{Bu}^n)_2$  droplets of radius 3—0.5  $\mu$  have been determined for different v.p. in a Hoag type of Millikan's oil-drop apparatus. Two interpretations are given. According to one the surface tension of a droplet decreases with increasing curvature. The other assumes a vapour film surrounding the droplet and leads to Kelvin's equation.

M. S. B.

Parachor, surface tension, and density of substituted phenols and phenolic ethers. A. BURAWOY and I. MARKOWITSCH-BURAWOY (J.C.S., 1936, 36—39).—Data are recorded for the hydroxy- and methoxy-azobenzenes and -benzaldehydes, and compared with vals. for the nitro-phenols and -anisoles. For the *o*-OH-compounds, but not the *o*-ethers, the parachor is  $<$  both calc. val. and vals. for the *m*- and *p*-compounds. Surface tensions and  $d$  for each set of isomeric ethers agree among themselves, but the vals. for *o*-OH-compounds are  $<$  for *m*-

and *p*-isomerides. *m*- and *p*-Nitrophenol and *p*-OH·C<sub>6</sub>H<sub>4</sub>·CHO are associated (as calc. from Ramsay-Shields const.), but the *o*-compounds and the Me ethers are normal. The anomalies of the *o*-compounds are probably due to interaction between the two *o*-substituents, which reduces their polarity, and those of *o*-hydroxyazobenzenes are not necessarily due to quinonoid structure. L. J. J.

**Parachor and ring structure. II. Spatial configuration of bridged-ring compounds.** S. K. RAY (J. Indian Chem. Soc., 1935, 12, 764—767; cf. A., 1934, 1058).—Data are given for cyclohexane, cyclohexanone, 3-methylcyclohexanone, cyclohexanol, cyclohexyl acetate, menthol, menthyl acetate, dipentene, camphoroxime, bromocamphor, camphene, bornyl acetate, fenchone, camphor benzoate, and  $\alpha$ -pinene. The structures are discussed. E. S. H.

**Parachor and chemical constitution. IV. Structure of aliphatic diazo-compounds.** S. K. RAY (J. Indian Chem. Soc., 1935, 12, 780—782; cf. A., 1935, 1306).—Data are given for the Me, Et, Pr<sup>n</sup>, and *n*-amyl diazoacetates between about 0° and 100°. The variation of parachor with temp. shows that these compounds are equilibrium mixtures of two forms. Low temp. favours the ring form, high temp. the open-chain structure. E. S. H.

**Constitution of formic acid and formates.** R. M. HALASYAM (J. Indian Chem. Soc., 1935, 12, 813—814).—Published work is discussed. Parachor determinations support the annexed formula as the most probable for the constitution of HCO<sub>2</sub>H. E. S. H.

**Interpolation equation for photo-densitometer charts of X-ray diffraction patterns.** W. SOLLER (Physical Rev., 1934, [ii], 46, 331). L. S. T.

**Influence of the slit on the distribution of intensities in the lines of a powder diagram.** A. ROGOZINSKI (Compt. rend., 1935, 201, 1354—1356).—Theoretical. T. G. P.

**Equation for X-ray crystal curves.** R. C. SPENCER (Physical Rev., 1934, [ii], 46, 1108—1109). L. S. T.

**X-Ray diffraction with calcite in several orders of reflexion.** L. G. PARRATT and F. MILLER (Physical Rev., 1936, [ii], 49, 280—288; cf. A., 1932, 1184).—Theoretical and experimental vals. of the four properties of reflexion, *i.e.*, width of the (*n*,  $-n$ ) rocking curve, % reflexion, coeff. of reflexion, and a factor determined by the shape of the (*n*,  $-n$ ) curve, are compared for calcite crystals in the  $\lambda$  ranges 0.71 <  $\lambda$  < 5.83 Å. in first order, 0.71 <  $\lambda$  < 2.75 Å. in second order, and at 0.71 and 1.54 Å. in third order, and 0.71 Å. in fourth and fifth orders. N. M. B.

**X-Ray examination of atomic vibrations in zinc and cadmium.** G. W. BRINDLEY (Nature, 1936, 137, 315—316).—The observed anomalous X-ray scattering of Zn and Cd is due to a greater lattice vibration along the *c* axis of the crystals than normal to it. L. S. T.

**Vacant positions in crystal lattice of ferriferous zinc blende.** H. BRAEKKEN (K. Norske Vid. Selsk. Forh., 1935, 7, 119—120; Chem. Zentr., 1935,

i, 3887).—Up to 25 at.-% of Fe, the ZnS lattice shows no expansion. From the observed X-ray intensities the presence of empty spaces in the lattice is inferred. J. S. A.

**Properties of graphite derived from the transformation of diamond.** P. CORRIEZ (Compt. rend., 1936, 202, 59—61).—Measurements of the X-ray spectrum, electrical resistance, and magnetic susceptibility are recorded for graphite prepared by heating diamond for 10 min. in vac. at 1900°. The X-ray spectrum differs from that of sugar C heated to 2000°. The differences are discussed. The resistance is < that of sugar C, but > that of natural graphite. The susceptibility was approx. the same. H. J. E.

**X-Ray interference in diamond as a wave-mechanical problem.** P. P. EWALD and H. HÖNL (Ann. Physik, 1936, [v], 25, 281—308).—Mathematical. The appearance of the forbidden diamond reflexions (222) is caused by a "zwischenladung" between the atoms which is inactive for higher interferences because of their considerable spread. W. R. A.

**(A) Changes of structure of crystals in an electric field. (B) Compensation apparatus and quantum fluctuation.** A. NÉMET (Helv. phys. Acta, 1935, 8, 97—116, 117—151; Chem. Zentr., 1935, i, 3517).—(A) X-Ray intensity measurements in electric fields are recorded for NaCl, calcite, quartz, mica, K Na and Na Rb tartrate, ice, (HCO<sub>2</sub>)<sub>2</sub>Ba, MgSO<sub>4</sub>, and tartar. The polarisability in various crystal directions is discussed.

(B) The experimental method is described. H. J. E.

**Electrolysis, dendritic growth, and discharge in alkali halide crystals.** A. VON HIPPEL (Z. Physik, 1936, 98, 580—596).—The movement of electrons and Cu ions through alkali halide crystals has been studied at 570°, and mobilities of the ions determined. Dendritic growths appear on reversal of the applied potential, and in NaCl the type of growth may change from the (100) to the (110) direction. A. B. D. C.

**Dendritic growth of crystals.** A. PAPAPETROU (Z. Krist., 1935, 92, 89—130).—Partly mathematical, partly a descriptive illustrated account under the following heads: part played by diffusion; effect of surface potential; observations on particular substances (especially inorg. halides); processes at the tip of the crystal; development near the tip and formation of branches; crystallisation from the melt. B. W. R.

**Growing and testing large single crystals of ice.** W. LEWIS (Physical Rev., 1934, [ii], 46, 328). L. S. T.

**Crystal structure of ice at low temperatures.** E. F. BURTON and W. F. OLIVER (Proc. Roy. Soc., 1935, A, 153, 166—172; cf. A., 1935, 686).—Details are given of the apparatus and method used. If the ice is formed above  $-80^\circ$ , the mols. have sufficient energy to arrange themselves into the highly organised state of a cryst. solid; at  $-90^\circ$ , the energy of the mols. is just enough to build up crystals along certain planes, whilst just below the crit. temp.,  $-110^\circ$ , there are sufficient mols. arranged in parallel planes

to give rise to two diffuse diffraction max., the size of the particles probably being of the order of  $10^{-7}$  cm.

L. L. B.

**Magnetic powder experiments on rolled nickel iron.** J. L. SNOEK (Physica, 1936, 3, 118—124).—Powder patterns (cf. Bitter, A., 1932, 1077) on isotropic and anisotropic samples are described. L. J. J.

**Crystal structure of cristobalite,  $\text{SiO}_2$ .** W. NIEUWENKAMP (Z. Krist., 1935, 92, 82—88).—The cell is pseudo-cubic,  $a_0$  7.02  $b_0$  6.92 Å., with 8 mols.  $\text{SiO}_2$ ,  $d$  (X-ray) 2.33, space-group  $P 4_2 2_1$ . Parameters are determined. B. W. R.

**Anomalous structures of fine crystalline silica.** N. A. SCHISCHAKOV (Compt. rend. Acad. Sci. U.R.S.S., 1936, 1, 19—22).—Structures of  $\text{SiO}_2$  have been studied by the electron-diffraction method. Fused vitreous  $\text{SiO}_2$  is not amorphous, but consists of deformed crystals of cristobalite,  $a$  6.87 Å.,  $c/a$  1.06. Fine-grained sand ( $\alpha$ -quartz) also shows a deformation in its crystallites,  $a$  4.735,  $c$  5.210 (quartz  $a$  4.903,  $c$  5.393). Pumice gives  $a$  6.82,  $c$  7.23 Å. R. S. B.

**X-Ray investigation of the glassy state.** N. VALENKOF and E. PORAI-KOSCHITZ (Nature, 1936, 137, 273—274).—Photographs showing gradual changes in the X-ray pattern on transition from vitreous  $\text{SiO}_2$  to a mixture of cristobalite and tridymite are reproduced. Similar transition patterns are obtained when  $\text{Na}_2\text{O-SiO}_2$  glasses are subjected to a rising temp. and increased time of heating, leading to the gradual appearance of the cryst. pattern. The lack of a sharp boundary between the glassy and cryst. states and the gradual growth of crystallites are thus demonstrated. L. S. T.

**Crystal structure of boron carbide.** F. LAVES (Nachr. Ges. Wiss. Göttingen, 1934, [ii], 1, 57—58; Chem. Zentr., 1935, i, 2944).—The lattice is trigonal,  $a$  5.62,  $c$  12.12 Å., giving 2.19 mols. of  $\text{B}_6\text{C}$  per unit cell. It is considered that the compound must be  $\text{B}_4\text{C}$ . J. S. A.

**Structure of aluminium boride,  $\text{AlB}_2$ .** W. HOFMANN and W. JÄNICHE (Z. physikal. Chem., 1936, B, 31, 214—222).—A detailed account of work already noted (this vol., 143). R. C.

**Crystal structure of the high-temperature form of silver iodide,  $\alpha\text{-AgI}$ .** L. W. STROOK (Z. physikal. Chem., 1935, B, 31, 132—136).—In  $\alpha\text{-AgI}$  the  $\text{Ag}^+$  ions are "molten," i.e., are distributed at random over the gaps between the  $\text{I}^-$  ions, which form a body-centred cubic lattice. In  $\alpha\text{-Ag}_2\text{HgI}_4$  three cations occupy a four-fold point position (A., 1934, 1056). The intensities of the X-ray diagram of  $\alpha\text{-AgI}$  have been recalculated. R. C.

**Cubic high-temperature modifications of cuprous and silver sulphides, selenides, and tellurides.** P. RAHLFS (Z. physikal. Chem., 1936, B, 31, 157—194).— $\alpha\text{-Ag}_2\text{S}$  and  $\alpha\text{-Ag}_2\text{Se}$  have a body-centred cubic lattice with 2 mols. in the unit cell, whilst  $\alpha\text{-Ag}_2\text{Te}$ ,  $\alpha\text{-Cu}_{1.8}\text{S}$ , and  $\alpha\text{-CuSe}$  are face-centred cubic, with 4 mols. in the unit cell. The lattice structures of  $\alpha\text{-Ag}_2\text{S}$  and  $\alpha\text{-Ag}_2\text{Se}$  are similar, the  $\text{Ag}^+$  ions being statistically distributed among the gaps between the anions, which form a somewhat distended body-centred cubic packing. With  $\alpha\text{-Ag}_2\text{Se}$

more anions occupy large gaps than smaller gaps, but with  $\alpha\text{-Ag}_2\text{S}$  the anions are distributed uniformly over all the gaps. Cubic  $\alpha\text{-Cu}_2\text{S}$  is obtained only if there is a deficiency of Cu, corresponding with  $\sim\text{Cu}_{1.8}\text{S}$ . The lattice of  $\alpha\text{-Cu}_{1.8}\text{S}$  is apparently similar in structure to that of  $\alpha\text{-Cu}_2\text{Se}$ . In  $\alpha\text{-Ag}_2\text{Te}$  and  $\alpha\text{-Cu}_2\text{Se}$  4 cations per unit cell form with the anions a Zn blende structure, whilst the remaining 4 are statistically distributed in gaps. In the above compounds the lattice changes from body-centred to face-centred when the ratio of the radius of the cation to that of the anion changes from 0.637 to 0.57. R. C.

**Crystal structure of potassium, rubidium, caesium, and thallium silicofluorides and of  $\text{LiMnO}_4 \cdot 3\text{H}_2\text{O}$ .** J. A. A. KETELAAR (Z. Krist., 1935, 92, 155—156).—The silicofluorides are isomorphous with  $(\text{NH}_4)_2\text{SiF}_6$ ; their lattice consts. and parameter vals. are tabulated. Lattice consts. are also given for  $\text{LiMnO}_4 \cdot 3\text{H}_2\text{O}$ . B. W. R.

**Crystal structure of thallium fluoride.** J. A. A. KETELAAR (Z. Krist., 1935, 92, 30—38).—The cell is rhombic, space-group  $V_{2h}^{23}$ ,  $a_0$  5.18,  $b_0$  5.495,  $c_0$  6.080 Å., 4 mols. in cell,  $d$  (X-ray) 8.48. This is a new type of AB structure and may be regarded as a deformed NaCl lattice. The high polarisability of  $\text{Tl}^+$  is discussed. B. W. R.

**Anhydrous sulphates of the magnesium series.** F. HAMMEL (Compt. rend., 1936, 202, 57—59).—Comparative X-ray data are recorded for the anhyd. sulphates of Mg, Mn, Fe, Co, Ni, Cu, and Zn. H. J. E.

**Symmetry of tetragonal nickel sulphate.** A. SCHOER (Natuurwetensch. Tijds., 1936, 17, 233—242).—Corrosion figures obtained by etching the (111) and (001) faces of  $\text{NiSO}_4 \cdot 6\text{H}_2\text{O}$  crystals indicate that they are holohedral, but those on the (112) and (101) faces correspond with a hemihedral structure.  $\text{NiSO}_4 \cdot 6\text{H}_2\text{O}$  belongs to the enantiomorphic class of the tetragonal system, and single crystals are either dextro- or laevo-rotatory, with  $\alpha$  1.55° per mm. for  $\lambda$  5893 Å. (cf. A., 1932, 986). D. R. D.

**Crystal structure of tetramminocadmium perchlorate,  $\text{Cd}(\text{NH}_3)_4(\text{ReO}_4)_2$ .** K. S. PITZER (Z. Krist., 1935, 92, 131—135).—The cell is face-centred cubic,  $a_0$  10.53 Å., 4 mols. in cell, space-group  $T_h^h$ . Approximations to the parameters are made. B. W. R.

**Configuration of bisdimethylglyoximoammine cobaltic chloride.**—See this vol., 460.

**Crystal structure of tetrahydrated nickelous acetate.** R. B. HULL (Physical Rev., 1934, [ii], 46, 329).— $a : b : c = 0.7216 : 1 : 0.4143$  have been confirmed goniometrically, and  $\beta$  93° 25' by Laue photographs. Rotation photographs give  $a_0$  8.49  $\pm$  0.03,  $b_0$  11.77  $\pm$  0.05,  $c_0$  4.87  $\pm$  0.03 Å. The unit cell contains 2 mols. of  $\text{Ni}(\text{OAc})_2 \cdot 4\text{H}_2\text{O}$ ;  $d^{20}$  is 1.717  $\pm$  0.001. L. S. T.

**Cell dimensions and space-group of calcium tartrate.** R. C. EVANS (Z. Krist., 1935, 92, 154—155).—The cell is orthorhombic,  $a_0$  9.20,  $b_0$  10.54,  $c_0$  9.62 Å., space-group  $P 2_1 2_1 2_1$ , 4 mols. in cell. B. W. R.

**Crystallised *p*-toluidine.** J. WYART (Bull. Soc. franç. Min., 1935, 58, 281—293).—The crystals,  $d$   $1.120 \pm 0.003$ , are orthorhombic with  $n_x$  1.68 and  $n_y$  1.58. X-Ray measurements give  $a$  5.95,  $b$  9.05, and  $c$  23.3 Å., with 8 mols. per unit cell. Details of mol. structure are given. L. S. T.

**Crystal structure of *p*-dinitrobenzene.** R. W. JAMES, G. KING, and H. HORROCKS (Proc. Roy. Soc., 1935, A, 153, 225—246).—The crystal structure of  $p$ -C<sub>6</sub>H<sub>4</sub>(NO<sub>2</sub>)<sub>2</sub> has been determined by the method of double Fourier series. Projections of the electron density on the 3 axial planes have been made, and the 18 independent parameters of the structure measured. The unit cell has  $a$  11.05,  $b$  5.42,  $c$  6.56 Å., and contains 2 mols. Space-groups,  $P 2_1/n$ ;  $d_{\text{calc}}$  1.64. The C<sub>6</sub> ring, although nearly a regular hexagon of side 1.40 Å., is slightly distorted, the length of one of each of the pairs of sides adjacent to the C-N linking being shortened to 1.32 Å. The distortion is due to the displacement of the C linked to the NO<sub>2</sub>. The C-N linking lies nearly in the plane of the ring, but is inclined at about 25° to the plane of the NO<sub>2</sub>. The N-O distances are 1.10 and 1.25 Å., respectively, and the O-O distances 2.14 Å. L. L. B.

**X-Ray investigations of the molecular structure of chitin.** A. N. J. HEYN (Proc. K. Akad. Wetensch. Amsterdam, 1936, 39, 132—135, and Nature, 1936, 137, 277—278).—The lattice structure of chitin is based on an arrangement of cellulose chains along the  $b$  axis of the unit cell with protein side-chains along the  $a$  axis. The  $c$  axis agrees with the side distance of the protein chains. A. G. P.

**X-Ray analysis of the orthorhombic crystalline modification of 1 : 2 : 5 : 6-dibenzanthracene.** J. IBALL (Nature, 1936, 137, 361; cf. this vol., 17).—The unit cell has  $a$  8.22,  $b$  11.39,  $c$  15.14 Å., giving  $d$  1.295 assuming 4 mols. of C<sub>22</sub>H<sub>14</sub> per unit cell; space-group  $Q_1^{15}$ - $Pcab$ . L. S. T.

**Liquid crystals of some cholesterol compounds.**—See this vol., 467.

**X-Ray study of the absorption of cyclopentanone by cellulose trinitrate.** M. MATHIEU and (MLLE.) T. PETITPAS (Compt. rend., 1936, 202, 46—47).—Changes in the X-ray diagram of cellulose nitrate, due to treatment with cyclohexane and cyclohexanone, are recorded. The results for treatment with the liquids or vapours resemble those for COMe<sub>2</sub> (cf. B., 1935, 1039). H. J. E.

**Electrical orientation of wool cells.** H. J. WOODS (Proc. Leeds Phil. Soc., 1935—1936, 3, 132—134).—A method of obtaining films of oriented wool cells, 20—30  $\mu$  thick, by sedimentation from an aq. suspension in an alternating electric field is described. The X-ray fibre photograph from such films was identical with that of normal  $\alpha$ -keratin in the untreated fibres. H. J. E.

**Supercrystalline organic compounds.** D. VORLÄNDER (Naturwiss., 1936, 24, 113—117).—A supercryst. compound is one in which the crystal forces are so strong that it does not fuse to give an amorphous melt, but decomposes on heating. This indicates that the mols. are held more firmly in the

crystal lattice than the atoms are held within the mol. The connexion between mol. structure and supercrystallinity is discussed. Compounds possessing this property usually have long chains of atoms in the mol., but this is not necessarily the sole cause of the phenomenon. In aromatic compounds it is more probably due to the cryst. association of rod-like units of medium length. The supercrystallinity of starch, cellulose, and proteins is due to the existence of both long chains and cryst. association of mols.

A. J. M.  
**X-Ray investigations of liquid crystals.** V. K. HERRMANN (Z. Krist., 1935, 92, 49—81).—Nine substances are investigated for liquid crystal behaviour with rising and falling temp., optically and with X-rays, especially in the neighbourhood of the optical transition points. For several a new interference effect, the "wide sharp ring," is found, ascribed to a closest hexagonal packing of nearly cylindrical mols. The ring does not vanish abruptly; its disappearance is discussed. B. W. R.

"Extra" rings in graphite electron diffraction patterns. G. I. FINCH and H. WILMAN (Nature, 1936, 137, 271—272).—Prominent "extra" electron diffraction rings have been obtained with natural and artificial graphite powders of high C content. The rings are due to planes, the spacings of which have no counterpart in the X-ray structure assigned to graphite. The thin crystals contain certain Bragg spacings not exhibited by thicker graphite. The formation of the "extra" rings is illustrated diagrammatically. L. S. T.

**Electron distribution in (NH<sub>4</sub>)<sub>2</sub>C<sub>2</sub>O<sub>4</sub>·H<sub>2</sub>O and the structure of the oxalate group.** S. B. HENDRICKS and M. E. JEFFERSON (J. Chem. Physics, 1936, 4, 102—107).—More accurate vals. of at. separations in the C<sub>2</sub>O<sub>4</sub> group of (NH<sub>4</sub>)<sub>2</sub>C<sub>2</sub>O<sub>4</sub>·H<sub>2</sub>O have been obtained from a Fourier analysis of the electron distribution on the (001) plane, using X-ray scattering data: C-C  $1.581 \pm 0.01$ , C-O  $1.25 \pm 0.02$ , and C-O  $1.23 \pm 0.02$  Å. with the angle O-C-O  $129 \pm 2^\circ$ . The O-C-O parts of the C<sub>2</sub>O<sub>4</sub> group are in planes at an angle of 28°, whilst in H<sub>2</sub>C<sub>2</sub>O<sub>4</sub>·2H<sub>2</sub>O,  $\alpha$ - and  $\beta$ -H<sub>2</sub>C<sub>2</sub>O<sub>4</sub> the parts are coplanar. M. S. B.

**Study of the structure of chloroform by electron diffraction.** C. DEGARD (Bull. Soc. chim. Belg., 1936, 45, 15—20).—Electron diffraction measurements are in accord both with the tetrahedral model and with Urbain's model of the CHCl<sub>3</sub> mol. J. W. S.

**Contact difference of potential between barium and silver. External work function of silver.** P. A. ANDERSON (Physical Rev., 1936, [ii], 49, 320—323).—A method for measuring const. and reproducible contact p.d. between metal surfaces, in which both surfaces are prepared by thermal vaporisation in a "gettered" vac., is described. The contact p.d. at liquid air temp. between microcryst. Ba and Ag is  $1.94 \pm 0.02$  volts; this, with the val. 2.39 volts for the work function of Ba, gives  $4.33 \pm 0.05$  volts for the work function of microcryst. Ag. This val. is compared with results from thermionic and photo-electric studies. N. M. B.

**Ferrites. III.** R. S. HILPERT and R. SCHWEINHAGEN (Z. physikal. Chem., 1935, B, 31, 1—11; cf. A., 1933, 1234).—The graph of magnetisability,  $\sigma$ , against composition,  $x$ , for  $\text{CuO-Fe}_2\text{O}_3$  mixtures exhibits a max. corresponding with  $2\text{CuO} : 3\text{Fe}_2\text{O}_3$ . The  $d$ - $x$  curve of slowly cooled mixtures has min. at  $2\text{CuO}, 3\text{Fe}_2\text{O}_3$  and  $\text{CuO}, 3\text{Fe}_2\text{O}_3$ , and a max. at  $\text{CuO}, 2\text{Fe}_2\text{O}_3$ , but if the mixture has been quenched the first min. is absent. Zn ferrites have a max.  $\sigma$  and min.  $d$  at  $2\text{ZnO}, 3\text{Fe}_2\text{O}_3$ , but the min.  $d$  is absent in quenched mixtures. The  $d$  suggests the existence of three series of Zn ferrites having, however, the same X-ray diagram. The  $d$ - $x$  curves of Sr ferrites and  $\text{Fe}_2\text{O}_3\text{-PbO}, \text{Fe}_2\text{O}_3$  mixtures have no max. or min. For all these ferrites the property-composition curves show no indication of metaferrites. R. C.

**Mathematical expression of the [magnetic] hysteresis curve.** J. NEUFELD (Compt. rend., 1936, 202, 125—126).—Theoretical. T. G. P.

**Analysis of dynamic curves for the magnetic permeability and losses in iron.** V. ARKADIEV (Compt. rend., 1936, 202, 39—41). H. J. E.

**Non-orthogonality and ferromagnetism.** J. H. VAN VLECK (Physical Rev., 1936, [ii], 49, 232—240).—Mathematical. N. M. B.

**Curie point of nickel.** E. C. STONER (Proc. Leeds Phil. Soc., 1935—1936, 3, 127—131).—A discussion of the derivation of the Curie point from experimental data. H. J. E.

**Discontinuities of magneto-resistance.** C. W. HEAPS (Physical Rev., 1934, [ii], 46, 1108; cf. A., 1934, 480).—A reply to criticism (A., 1935, 287). L. S. T.

**Method of investigating the Hall effect.** H. S. HATFIELD (Proc. Physical Soc., 1936, 48, 267—276).—An improved method, avoiding thermo-electric and other disturbing effects, is described and checked approx. for Al, Cu, Pb, Ni, Ag, Zn, and Sn. N. M. B.

**Method for determining the optical constants of crystals and its application to certain organic compounds.** R. G. WOOD and S. H. AYLIFFE (Phil. Mag., 1936, [vii], 21, 321—336; cf. A., 1935, 434).—Using the immersion method with a polarising microscope and a special microscope stage-goniometer, measurements were made of the principal refractive indices and orientation of the indicatrix of red and yellow picryl-*p*-toluidine, picrylaniline,  $\text{Ph}_2\text{O}$ , and  $\text{Ph}_2\text{SO}_2$ . N. M. B.

**Superficial optical properties of spar.** R. DE MALLEMANN and F. SUHNER (Compt. rend., 1935, 201, 1344—1346).—The results of an examination of the optical properties of a beam of rectilinearly polarised monochromatic light after reflexion at a cleavage surface of spar indicate the existence of an isotropic surface layer 70 Å. thick. T. G. P.

**Crystallochemical relations between germanium and silicon.** W. SCHÜTZ (Z. physikal. Chem., 1936, B, 31, 292—308).—The pairs  $\text{Zn}_2\text{SiO}_4$  and  $\text{Zn}_2\text{GeO}_4$ ,  $\text{Be}_2\text{SiO}_4$  and  $\text{Be}_2\text{GeO}_4$ , and  $\text{Cs}_2\text{SiF}_6$  and  $\text{Cs}_2\text{GeF}_6$  are probably isomorphous. The lattice consts. have been determined. In the heaviest

flint glass of the type *S* 231 the  $\text{SiO}_2$  may be replaced by an equal wt. of  $\text{GeO}_2$ , giving a glass corresponding approx. with  $\text{Pb}_2\text{GeO}_4$  and having  $d$  6.92,  $n_D$  2.100, and  $n_F - n_G = 0.073$ . The optical consts. of various  $\text{PbO-GeO}_2$  glasses have been measured (cf. B., 1927, 42). R. C.

**Rock-salt structure of  $\text{Li}_2\text{TiO}_3$  and its formation of mixed crystals with  $\text{MgO}$  and  $\text{Li}_2\text{Fe}_2\text{O}_4$ .** E. KORDES (Z. Krist., 1935, 92, 139—153).—Lattice consts.,  $d$ , and  $n$  of  $\text{Li}_2\text{TiO}_3$  are determined; the intensities indicate a statistical distribution of  $\text{Li}^+$  and  $\text{Ti}^{4+}$ . A continuous series of mixed crystals is formed with  $\text{MgO}$ , the lattice consts. and  $n$  of which alter continuously with the composition. A more complicated mixed crystal of  $\text{MgO}$ ,  $\text{Li}_2\text{Fe}_2\text{O}_4$ , and  $\text{Li}_2\text{TiO}_3$  is prepared and examined; its consts. can be deduced by an additive law. Possible applications to ceramics and refractories are discussed. B. W. R.

**Refractive indices of metallic films showing Newton's rings.** K. PROSAD and B. N. GHOSH (Indian J. Physics, 1936, 10, 49—53).—Previous work (*ibid.*, 1933—1934, 3, 425) on the coloured concentric rings, similar to Newton's rings, obtained on the Al cathode of a Hadding's X-ray tube with a Cu anti-cathode, has been extended to the examination of the rings obtained using a Pt anti-cathode. M. S. B.

**Rotation of the plane of polarisation by oblique crystalline refraction.** G. BRUNAT and L. WEIL (Bull. Soc. franç. Min., 1935, 58, 294—313).—Measurements on quartz and calc spar verify, for small angles of incidence, Potier's theory and MacCullagh's formula. L. S. T.

**Plastic deformation of cadmium single crystals.** R. ROSCOE (Phil. Mag., 1936, [vii], 21, 399—406).—Measurements were made on the bending of single-crystal wires of very pure Cd, and of Cd containing 0.11% Pb and 0.03% Zn. Results indicate that, when the stress over the glide-planes is not uniform, slip begins when the max. val. of the resolved shear stress reaches the crit. val. for deformation under uniform stresses. Surface oxidation produces, in resistance to plastic deformation, an increase that cannot be due to the cohesion of the oxide film, but probably arises from the healing of submicroscopic cracks in the film. N. M. B.

**Plasticity of deformed metals.** D. V. KONVISAROV (Compt. rend. Acad. Sci. U.R.S.S., 1935, 4, 139—140).—For Al, Cu, and Fe the plasticity diminishes as the torsional angles increase. W. R. A.

**Determinative elastic and deformation constants of crystals, with applications to isotropic substances.** P. BECHTEREV (Z. Krist., 1935, 92, 1—29).—Theoretical. A classification of elastic consts. on a suggested scale of "gradation." The terms hygro-, ortho-, plagio-, and sclero-morphic are given to extreme concepts of elastic behaviour; e.g., a fully hygomorphic substance has liquid fluidity, and a fully scleromorphic one resists changes of form without limit, but does not oppose vol. alteration. Published elasticity figures for many

substances (some isotropic) are summarised and classified on this "gradation" scale. B. W. R.

**Akulov's theory of coercivity.** V. S. MESSKIN and B. E. SOMIN (Z. Physik, 1936, 98, 610—623).—Experiment disproves Akulov's theory (A., 1931, 898). A. B. D. C.

**Abrasion hardness of dolomite.** H. TERTSCH (Z. Krist., 1935, 92, 39—48).—The amount of wear of a dolomite crystal by an abrasive plate is recorded for various directions and planes. The cleavage plane gives an asymmetric hardness figure; the basis plane gives threefold symmetry. B. W. R.

**Polymorphic transformation of simple ionic lattices. I. Transformation of caesium chloride into sodium chloride lattice by heating.** G. WAGNER and L. LIPPERT (Z. physikal. Chem., 1936, B, 31, 263—274).—At  $445 \pm 5^\circ$  the lattice of ordinary CsCl changes into a lattice of the NaCl type, with lattice const.  $7.02 \times 10^{-8}$  cm., the heat of transition being 1.8 kg.-cal. Between  $20^\circ$  and  $580^\circ$  CsBr, CsI, TlCl, TlBr, and TlI exhibit no transition points. R. C.

**Transition in aluminium at  $79^\circ$ .** W. BAND (Physical Rev., 1934, [ii], 46, 934—935).—The variety of hysteresses observed on heating an Al wire show that there is a transition of some kind at  $79 \pm 0.5^\circ$ . L. S. T.

**Distortion of  $\beta$ -brass and iron crystals.** (Miss) C. F. ELAM (Proc. Roy. Soc., 1936, A, 153, 273—301).—A comparison of the results obtained from experiments on the distortion in tension of the body-centred cubic metals, Fe and  $\beta$ -brass, indicates that there is no essential difference between them. Stress-strain curves of the crystals are given, and the fracture of  $\beta$ -brass crystals in tension and in rolling is described. The direction of slip is not always a crystal direction, and it is suggested that the deformation is brought about by movements of a complex nature, and not by slip on any definite crystal plane. L. L. B.

**Mott's theory of liquid metals, and the transition points of metals and other solids.** R. H. FOWLER (Helv. phys. Acta, 1934, 7, Suppl. II, 72—80; Chem. Zentr., 1935, i, 3386).—Mott's theory (A., 1934, 1300) is discussed in relation to the changes in state of metals, alloys,  $\text{NH}_3$  halides, and other substances. H. J. E.

**Hume-Rothery conception of the metallic state.** C. D. NIVEN (Phil. Mag., 1936, [vii], 21, 291—299).—The Hume-Rothery relation is restated for the periodic groups IIIB—VIIB in the form "in crystallising each atom has  $6-N$  near neighbours, where  $N$  is the no. of electrons in the  $p$  system." The bearing of the relation on conduction and superconductivity is discussed. R. S. B.

**Electrical resistance of aluminium at low temperatures.** H. A. BOORSE and H. NIEWODNICZAŃSKI (Proc. Roy. Soc., 1936, A, 153, 463—475; cf. A., 1935, 814).—The electrical resistances of 6 polycryst. Al wires were measured at  $0^\circ$  and liquid  $\text{N}_2$  and liquid  $\text{H}_2$  temp., and those of 4 wires drawn from 99.995% pure Al at the temp. of liquid

He. Reduced resistivities computed by means of the Mathiessen-Nernst formula were in agreement with these calc. from the Grüneisen formula (A., 1933, 452) for liquid  $\text{N}_2$  temp., but not for liquid  $\text{H}_2$  temp. L. L. B.

**Tension coefficients of resistance of the hexagonal crystals zinc and cadmium.** (Miss) M. ALLEN (Physical Rev., 1936, [ii], 49, 248—253; cf. A., 1933, 559).—The coeffs. have been measured, and are independent of secondary orientation. The curves correspond with those representing the points as functions of the primary orientation. Results are discussed in relation to the Bridgman-Cookson theory (cf. *ibid.*, 1935, [ii], 47, 194). N. M. B.

**Mean free electronic path in silver from electrical conductivity of very thin silver threads.** A. EUCKEN and F. FÖRSTER (Nachr. Ges. Wiss. Göttingen, 1934, [ii], 1, 129—137; Chem. Zentr., 1935, i, 2954).—A résumé of and additions to published work (A., 1935, 153). J. S. A.

**Variations in current in a conductor.** L. BRILLOUIN (Helv. phys. Acta, 1934, 7, Suppl. II, 47—67; Chem. Zentr., 1935, i, 2954).—Current variations are calc. from the distribution of electrons by a probability method. Magnetic interaction between the electrons is assumed. J. S. A.

**Temperature variation of the susceptibility of oxygen.** H. LÜES (Z. Physik, 1936, 98, 537—547).—The susceptibility of  $\text{O}_2$  shows increasing deviation from  $\chi T = \text{const.}$  with rise of temp. from  $286^\circ$  to  $600^\circ$  abs. A. B. D. C.

**Susceptibility measurements for oxygen and inert gases.** K. E. MANN (Z. Physik, 1936, 98, 548—560).—The susceptibility of  $\text{O}_2$  is independent of density and field strength from 90 to 750 mm. Hg, and from 1800 to 15,000 oersted. Vals. obtained for the inert gases are compared with theoretical vals. A. B. D. C.

**Magnetic studies on graphite and graphitic oxides.** N. GANGULI (Phil. Mag., 1936, [vii], 21, 355—369).—The principal susceptibilities of cryst. graphite along the vertical axis and along directions in the basal plane are  $-22 \times 10^{-6}$  and  $-0.5 \times 10^{-6}$  per g., respectively. By treating with conc.  $\text{H}_2\text{SO}_4$  and  $\text{HNO}_3$  to form "blue graphite" the abnormal diamagnetism along the vertical axis is nearly destroyed, and that along the basal plane is almost unchanged; the anisotropy is of the same order of magnitude as in aromatic mols. containing several condensed  $\text{C}_6\text{H}_6$  nuclei:  $1.3 \times 10^{-6}$  per g. content of C. A diminution in the particle size of graphite has nearly the same effect as oxidation as above. These effects are attributed to a breaking up of the metallic linkings in graphite responsible for abnormal diamagnetism. N. M. B.

**Explosive antimony. III. Magnetic susceptibility.** C. C. COFFIN (Canad. J. Res., 1935, 13, A, 120—125; cf. A., 1934, 1297).—Explosive Sb is less diamagnetic than the ordinary polycryst. metal. magnetic susceptibilities being  $-0.38 \times 10^{-6}$  and  $-0.88 \times 10^{-6}$ , respectively. Explosive or amorphous Sb should be regarded as a true glass of supercooled liquid. E. E. A.

**Temperature variation of [magnetic] susceptibility of solid nitric oxide.** E. LIPS (Helv. phys. Acta, 1935, 8, 247—263; Chem. Zentr., 1935, ii, 189).— $\chi$  for solid NO between 63° and 90° abs. is const., and much < the theoretical val. The difference is attributed either to the formation of double mols., or to alterations in the electronic levels due to electric fields in the crystal lattice. J. S. A.

**Magnetic susceptibility of vapours of some organic substances.** J. SHUR and S. SIDOROV (Nature, 1936, 137, 317).—A redetermination of the magnetic susceptibility of CS<sub>2</sub> showed no change in the vals. for the vapour and liquid states (cf. A., 1935, 14).

L. S. T.

**Magnetic behaviour of alums of the iron group.** A. SIEGERT (Physica, 1926, 3, 85—90).—Theoretical. For Cr<sup>+++</sup>, Mn<sup>+++</sup>, and Fe<sup>+++</sup>, the Bose-Stoner relation can be explained on the basis of the known lattice structure. For Ti<sup>+++</sup> and V<sup>+++</sup>, deviations from cubic symmetry must be taken into account. L. J. J.

**Paramagnetic relaxation.** C. J. GORTER (Nature, 1936, 137, 190).—The relaxation time of the magnetic vector is approx. 10<sup>-10</sup> sec. for Fe<sup>+++</sup> alum.

L. S. T.

**Symmetry of the thermo-electric effects in single crystals.** H. P. STABLER (Physical Rev., 1934, [ii], 46, 938).

L. S. T.

**Variation with temperature of the absorption of ultrasonic waves by liquids.** E. BAUMGARDT (Compt. rend., 1936, 202, 203—204).—The absorption of ultrasonic waves  $\nu = 7.9578 \times 10^6$  by H<sub>2</sub>O at 18—40° has been measured. The coeff. of absorption  $\propto \eta \rho_0 V_0^3$ , where  $\eta$  is the coeff. of viscosity,  $\rho_0$  the density, and  $V_0$  the velocity of sound. T. G. P.

**Existence of diffusion of ultrasonic waves in liquids.** P. BIQUARD (Compt. rend., 1936, 202, 117—119).—The existence of diffusion in ultrasonic waves (Lucas, this vol., 148)  $\nu = 7.96 \times 10^6$  sec.<sup>-1</sup> in PhMe has been confirmed experimentally. T. G. P.

**Ultrasonic experiments.** H. SACK (Helv. phys. Acta, 1934, 7, 657—658; Chem. Zentr., 1935, i, 3767—3768).—Relative velocities of propagation of ultrasonic waves in H<sub>2</sub>O, C<sub>6</sub>H<sub>6</sub>, and aq. ZnSO<sub>4</sub> are recorded. Measurements of absorption in solids show a greater absorption in imperfect NaCl crystals than in perfect crystals, and reveal considerable differences in the vol. absorption of different metals. J. S. A.

**Ultrasonic waves and chemical investigation.** G. SCHMID (Angew. Chem., 1936, 49, 117—127).—A review. A. J. M.

**Transition temperature.** R. PEIERLS (Helv. phys. Acta, 1934, 7, 81—83; Chem. Zentr., 1935, ii, 184).—Theoretical. The phenomena of transition and melting are considered from the viewpoint of displacements of mutually coupled, regularly arranged atoms, held by cohesive forces, the m.p. being that temp. above which the magnitude of the induced displacement increases with distance. J. S. A.

**Specific heat of solid helium and melting heat of helium.** W. H. KEESOM and (Miss) A. P. KEESOM (Physica, 1936, 3, 105—117).—Data for  $c_v$  of solid He are recorded in the region 1.2—3.0° abs. and  $d$  0.20—

0.22.  $c_v$  increases more rapidly with  $T$  than would follow from Debye's relation.  $\Theta_D$  is > the val. given by Kaischew and Simon (A., 1934, 589), and changes from 37 at 1.2° and  $d$  0.218 to 25 at 2.18° and  $d$  0.201, the  $\Theta$ - $T$  relation being linear. The heats of fusion at 2.5°, 3.0°, and 3.5° abs. are 0.835, 1.089, and 1.365 g.-cal. per g., respectively. Data for co-existing solid and liquid densities are also recorded. L. J. J.

**Effect of dissolved air on the specific heat of water over the range 15—20°.** E. O. HERCUS (Proc. Physical Soc., 1936, 48, 282—284; cf. *ibid.*, 1935, 47, 1003).—The effect is calc. thermodynamically from the solubility data for the case when no air is liberated. The sp. heat of H<sub>2</sub>O saturated with air at 20° and atm. pressure is > that of air-free H<sub>2</sub>O by  $6 \times 10^{-6}$  g.-cal. per g. N. M. B.

**Atomic heat of nickel at low temperatures.** K. CLUSIUS and J. GOLDMANN (Z. physikal. Chem., 1936, B, 31, 256—262; cf. A., 1935, 574).—Measurements at 10—30° abs. show an anomalous fall of sp. heat with temp., which is reconcilable with neither Bloch's  $T^{3/2}$  law for ferromagnetism nor Sommerfeld's  $T$  law for free electrons (cf. this vol., 148). R. C.

**Specific heat of Seignette salt. I. Anomaly at upper Curie point.** A. A. RUSTERHOLZ (Helv. phys. Acta, 1935, 8, 39—54; Chem. Zentr., 1935, i, 2957).—Work reported previously (A., 1935, 1454) is described in detail. Anomalies in the Curie point, calc. from  $C_p$  and from the dielectric const., and in the inner field are discussed. J. S. A.

**Heat capacity, entropy, and free energy of rubber hydrocarbon.** N. BEKKEDAH and H. MATHESON (J. Res. Nat. Bur. Stand., 1935, 15, 503—515).—Vals. of heat capacity at 14—320° abs. are given for the cryst. and amorphous forms of rubber, prepared by digesting latex with steam at 190° and extracting resins and hydrolysis products with EtOH and H<sub>2</sub>O. There was a transition temp. at approx. 199° abs. The cryst. form fuses at 284° abs. The entropy and standard free energy of formation were calc. H. J. E.

**Thermal properties of an incompletely degenerate Fermi gas.** N. F. MOTT (Proc. Camb. Phil. Soc., 1936, 32, 108—111).—Mathematical. The sp. heat and paramagnetic susceptibility of an electron gas obeying the Fermi-Dirac statistics are calc. for all temp. including those for which the gas is partly degenerate. A. J. M.

**Aggregative states. II. Ratio of the temperature interval of existence of substances in the solid and liquid states.** E. I. ACHUMOV (J. Gen. Chem. Russ., 1935, 5, 1445—1454; cf. this vol., 21).—Theoretical. The aggregative coeff.,  $\phi = (T_b - T_m)/T_m$ , where  $T_b$  is the b.p. and  $T_m$  the m.p. (abs.), is evaluated for a no. of elements and compounds, and certain regularities are pointed out. R. T.

**Density of liquid phosphorus.** S. DOBRIŃSKI (Bull. Acad. Polonaise, 1935, A, 253—259).—Data are recorded at 7—68°:  $d = 1.78685 - 0.0009386t$ . T. G. P.

**Density of mercury at 0°.** T. BATUECAS and E. L. CASADO (J. Chim. phys., 1936, 33, 41—50).—

$d_4^0$  for Hg cleaned chemically, doubly distilled, and fractionated is  $13.59539 \pm 0.00001$  g. per ml.

J. W. S.

**Carbon monoxide [rectilinear diameter] and helium.** E. MATHIAS and C. A. CROMMELIN (Ann. Physiq., 1936, [xi], 5, 137—166).—Densities of liquid and saturated vapour for CO between  $132.91^\circ$  ( $T_c$ ) and  $68.13^\circ$  abs. have been measured. The law of the rectilinear diameter is approx. obeyed, giving  $d_c$  0.3010 and crit. coeff. ( $K$ ) 3.394; earlier vals. for other gases are corr. The true diameter has a point of inflexion, and gives  $d_c$  0.3050 and  $K$  3.440. The difference between the true and rectilinear diameters is discussed. The temp. variations of  $p$ ,  $L$ , and internal and external heats of vaporisation are calc. by Clapeyron's equation. The density curve of He (cf. A., 1926, 774) is corr. Application of Clapeyron's equation as above shows that the sp. heat of the saturated vapour is negative, in agreement with theory.

L. J. J.

**Vapour pressure of silicon tetrachloride.** K. KEARBY (J. Amer. Chem. Soc., 1936, 58, 374—375).—Data for the range  $0$ — $60^\circ$  can be expressed by  $\log p = 7.6414 - 1572.3/T$ , from which it follows that the b.p. at 760 mm. is  $57.0^\circ$ .

E. S. H.

**Vapour pressures of metals.** A. EUCKEN (Metallwirts., 1936, 15, 27—31, 63—68).—A crit. survey of existing information on both experimental and theoretical aspects of the subject.

C. E. H.

**Free energies and vapour pressures of the alkali metals.** A. R. GORDON (J. Chem. Physics, 1936, 4, 100—102).—From spectroscopic data, the free energies of the diat. vapours of  $K_2$ ,  $Na_2$ , and  $Li_2$ , and the equilibrium consts. for dissociation into the monat. forms, have been calc. From these consts. and v.-p. data, equations for the partial pressures of atoms and mols. in the saturated vapour, for temp. up to the normal b.p., have been deduced. The entropies of solid Na and K have also been calc. from the v.-p. equation.

M. S. B.

**Isotherms of  $CO_2$ .** I. Between  $0^\circ$  and  $150^\circ$  and pressures from 16 to 250 atm. (Amagat densities 18—206). A. MICHELS and (Mrs.) C. MICHELS. II. Between 70 and 3000 atm. (Amagat densities 200—600). A. MICHELS, (Mrs.) C. MICHELS, and H. WOUTERS (Proc. Roy. Soc., 1935, A, 153, 201—214, 214—224).—I. The technique and results of isotherm measurements up to densities of 200 Amagat units are described. The vals. of  $[(pv)_t - (pv)_{75}]/(t - 75)$  are calc. and plotted against  $t$ , and from the slope of the curves it can be seen that the sp. heat  $c_p$  increases with increasing density  $d$ .

II. The method has been modified for higher densities (200—600 Amagat units).  $c_p$  increases with increasing  $d$  to a max. for  $d = 226.7$ , then decreases and passes through a min. for  $d$  390—460 Amagat units. The position of the max. coincides with the density of the crit. point.

L. L. B.

**Data of state of phosphine at low pressures and from  $190^\circ$  to  $300^\circ$  abs.** E. A. LONG and E. A. GULBRANSEN (J. Amer. Chem. Soc., 1936, 58, 203—205).—Apparatus and technique for comparing

directly the properties of a gas at low temp. and pressure with the known behaviour of He are described. Data have been determined for  $PH_3$ , and the second virial coeff.  $B$  calc. The dependence of  $B$  on temp. is well represented by a power series in  $1/T$ .

E. S. H.

**Internal pressure in gases. VII.** K. JABE CZYŃSKI (Rocz. Chem., 1935, 15, 450—459; cf. A., 1934, 952).—Van der Waals' equation is expressed as  $(p + P)(w - b) = RT$ , where  $p$  is the external pressure, and  $P$ , the internal pressure, is the resultant of the cohesive and repulsive forces between the mols., and  $= \{a - f(w)T\}/w^2$ . The vals. of  $P$  for various gases at different  $p$ ,  $T$ , and  $w$  have been evaluated, and it is shown that  $P$  rises abruptly with transition from the gaseous to the liquid state, showing that this process is not continuous.

R. T.

**Constants in the equation of state for the rare gases.** E. BRANDER and K. TAMMINEN (Soc. Sci. Fenn., Comm. phys.-math., 1935, 8, No. 5, 6 pp.; Chem. Zentr., 1935, i, 3519).—Vals. for van der Waals'  $a$  are calc., using the Wasastjerna equations (cf. A., 1935, 691).

H. J. E.

**Thermal expansions of alloyed bismuth crystals in the region of the eutectic m.p.** A. GOETZ, J. W. BUCHTA, and T. L. HO (Physical Rev., 1934, [ii], 46, 538; cf. A., 1935, 156).

L. S. T.

**Thermal conductivity of carbon dioxide.** T. L. IBBS (Phil. Mag., 1936, [vii], 21, 508—509).—An examination of Archer's conductivity-temp. curve for  $CO_2$  (cf. A., 1935, 691) appears to indicate an effect due to a change in the nature of the intermol. field at  $140^\circ$ .

N. M. B.

**Thermal conductivities of metals and alloys.** J. W. DONALDSON (Metallurgia, 1936, 13, 159—160).—A review of recent work.

**Method of determining the state of degeneration of a gas.** A. VAN ITTERBEEK (Nature, 1936, 137, 109).—The method consists in determining  $\eta$  at different temps. and then calculating the mean velocity of the mols. from Stokes' formula. With  $O_2$  at  $293^\circ$ ,  $90^\circ$ , and  $72^\circ$  abs. the val. obtained for the mean velocity agrees with that deduced from classical theory.

L. S. T.

**Influence of an electric field on the viscosity of liquids.** P. T. SOKOLOV and S. L. SOSINSKI (Compt. rend. Acad. Sci. U.R.S.S., 1935, 4, 135—138).—The variation in the time of flow through the capillary of an Ostwald viscosimeter with and without an applied electric field has been investigated for  $COMe_2$ ,  $EtI$ ,  $MeOH$ ,  $Et_2O$ ,  $CHCl_3$ ,  $C_6H_{14}$ , and  $C_6H_6$  at different temp. Non-polar mols. are uninfluenced; polar mols. show the greatest variations at higher field strengths, the ratios of the times of flow with the applied field to the times of flow with no applied field increasing as the field strengths are increased. The higher is the dipole moment of the mol., the greater is the extent to which it is influenced.

W. R. A.

**Viscosity of liquid gallium over an extended range of temperature.** K. E. SPELLS (Proc. Physical Soc., 1936, 48, 299—311).—Using a special technique to overcome surface-film difficulties, measurements are given for  $\eta$  over the temp. range  $30$ —

1100°, and are compared with vals. calc. on Andrade's theory of variation with temp. At 1100° the decrease of  $\eta$  is 2% per 100°. N. M. B.

***p-v-T* relations of gaseous mixtures.** E. R. GILLILAND (Ind. Eng. Chem., 1936, 28, 212—215).—The isometric (*p-T* curve, *v* const.) for a pure gas approximates closely to a straight line at *T* > crit. temp. The slope of the isometric for a mixture can be obtained from the molal average of the slopes of the isometrics for the constituents, all measured at the same mol. concn. This fact, in addition to a simple method for obtaining the internal pressure from the isometrics, enables the *p-v-T* relationships for a mixture to be calc. more accurately than by the use of Dalton's or Amagat's laws. The theory is applied to  $A-C_2H_4$ ,  $H_2-CO$ , and  $CH_4-N_2$  mixtures. A. J. M.

**Viscosities of deuterium-hydrogen mixtures.** A. B. VAN CLEAVE and O. MAASS (Canad. J. Res., 1935, 13, B, 384—389; cf. A., 1935, 432, 691, 1455).—Further measurements at 22° have shown that the diameters of  $D_2$ , HD, and  $H_2$  mols. are identical. Variation of  $\eta$  with the temp. has been derived from measurements at -78.5° and -183.4°. Jeans' temp.-viscosity relation holds approx. for the mixtures. A comparison has been made of various equations which are said to express the dependence of  $\eta$  on the composition of mixtures. E. E. A.

**Description of binary solutions.** F. O. KOENIG (J. Amer. Chem. Soc., 1936, 58, 317—318).—Theoretical. The changes associated with different modes of description (*i.e.*, the formula assigned to each component) are discussed. E. S. H.

**Densities and refractive indices of bromoform-benzene mixtures.** J. L. WHITMAN and L. CLARDY (J. Amer. Chem. Soc., 1936, 58, 237—239).—Data at 30° are recorded. The *d*-composition relation conforms closely to that for an ideal system. E. S. H.

**Viscosity formula for binary mixtures, the association degrees of constituents being taken into consideration.** XII. T. ISHIKAWA and T. BABA (Bull. Chem. Soc. Japan, 1936, 11, 8—18).—The Ishikawa viscosity formula has been applied to the experimental data for binary mixtures such as  $C_6H_6$  with alcohols or AcOH, in which one component shows marked association. The calc. and observed vals. of  $\eta$  are in close agreement. A comparison is made with the Thiesen formula for gaseous mixtures (cf. A., 1929, 500). Where there is a max.,  $\eta$  calc. from the latter is not quite coincident with the observed  $\eta$ , but no such divergence occurs with the Ishikawa formula (cf. A., 1929, 387). M. S. B.

**Viscosities of liquid mixtures.** K. E. SPELLS (Trans. Faraday Soc., 1936, 32, 530—540).—Viscosities of mixtures of  $PrOH$ ,  $Bu^iOH$ ,  $CH_2Bu^iOH$ , and  $CH_3CH_2OH$  with  $C_6H_6$  have been measured at 22°. The results, together with other data, are used to test the validity of a single-const. expression connecting  $\eta$  with the composition. The curves for the two amyl alcohols show no anomalies corresponding with those shown by the dielectric const. F. L. U.

**Investigation of equilibrium between a boiling liquid and its vapour by thermal analysis.** L.

MEYER (Z. physikal. Chem., 1936, 175, 275—283).—The determination of the b.p. of a liquid mixture and the condensation point of a mixture of vapours by heating and cooling curves, respectively, is described. The apparatus is suitable for determining the proportion of condensable constituents in a gas mixture. R. C.

**Ferromagnetism and liquid mixtures.** C. ZENER (Physical Rev., 1934, [ii], 46, 824—825).—Analogies between the development of magnetisation below the Curie point and the separation of two phases from a homogeneous liquid mixture of two types of atoms are discussed. L. S. T.

**Crystal structure of beryllium alloys.** L. MISCH (Metallwirts., 1936, 15, 163—166).—Alloys of Be with several metals of the transition series have been examined, the majority being of the type  $AB_2$  ( $B=Be$ ). The results are discussed in relation to the Hume-Rothery rule (cf. A., 1935, 926). C. E. H.

**Solidification diagram of copper-tin alloys.** W. BRONIEWSKI, J. T. JABLONSKI, and S. MAJ (Compt. rend., 1936, 202, 305—307).—A complete fusion diagram is given. Formation of the compounds  $Cu_4Sn$ ,  $Cu_3Sn$ , and  $Cu_2Sn$  is indicated. H. J. E.

**Zinc-indium alloy system.** C. L. WILSON and E. A. PERETTI (Ind. Eng. Chem., 1936, 28, 204—205).—Thirty alloys have been examined, and the equilibrium diagram has been obtained. The eutectic contains 96% In and 4% Zn, and the eutectic temp. is 143.5°. The alloys become softer as the proportion of In is increased. A. J. M.

**Phase diagram of the system silver-gallium.** F. WEIBKE, K. MEISEL, and (FRL.) L. WIEGELS (Z. anorg. Chem., 1936, 226, 201—208).—Thermal, microscopic, and X-ray observations have been made. The data for the Ag-rich alloys agree with those of Hume-Rothery *et al.* (A., 1934, 725). Five series of mixed crystals are indicated. The system is compared with other systems containing Ag and Ga. The at. vol. of Ga in Ag, like that of Al, is > in Cu. M. S. B.

**Velocity of transformation in cadmium-magnesium alloys in the region of composition  $MgCd$ .** N. L. STEPANOV and S. A. BULACH (Compt. rend. Acad. Sci. U.R.S.S., 1935, 4, 147—151).—The electrical conductivity of alloys tempered from above the transition points and also of annealed alloys has been measured at 25°, 50°, 75°, and 100°. The annealed alloys, stable at low temp., have the highest conductivity. Transition velocities have been determined at 100°. W. R. A.

**(A) Platinum-antimony alloys. (B) Platinum-rhodium alloys.** V. A. NEMILOV and N. M. VORONOV (Z. anorg. Chem., 1936, 226, 177—184, 185—191; cf. A., 1935, 440).—(A) The presence of a solid solution on the Pt side seems to be indicated.

(B) The thermoelectric power of systems of chemically pure Pt with different Pt-Rh alloys increases with the concn. of Rh, but more rapidly at low than at high concn. Pt-Rh alloys are not readily attacked by acids. By heating at 750° a slight surface oxidation takes place on alloys con-

taining  $>10\%$  Rh. At  $1150^\circ$  the oxide is dissociated leaving a bright metallic surface. M. S. B.

**Transformation in the copper-gold alloy  $\text{Cu}_3\text{Au}$ .** C. SYKES and H. EVANS (J. Inst. Metals, 1936, 58, Advance copy, 443–472).—From X-ray examination and from measurements of the electrical resistance and sp. heat of the Cu–Au alloy with 25 at.-% Au it is shown that the general character of the transformation is similar to that predicted by Bragg and Williams (A., 1934, 954); it takes place continuously from the crit. temp. to a very low temp. and the equilibrium is a dynamic one. The at. rearrangement proceeds first by the formation of nuclei having a relatively high degree of order and then, at const. temp., by the growth of these nuclei to a size approximating to that of the individual crystals, or, at gradually falling temp., by growth of the nuclei accompanied by an increase in their degree of order due to the fall in temp. Since nuclei formation is not taken into account in the statical theory of super-lattices it follows that the actual rate of relaxation into the equilibrium state differs considerably from that predicted by the theory. Very appreciable differences in the properties of the alloy can be effected by variations in the heat-treatment, but all are strictly reproducible, which confirms the conclusion that the transformation is an intra-cryst. phenomenon almost independent of grain-boundary effects. A. R. P.

**I. Paramagnetism of nickel alloys.** C. MANDERS. **II. Magnetic properties of the metallic state and energy of interaction between magnetic atoms.** L. NÉEL (Ann. Physique, 1936, [xi], 5, 167–231, 232–279).—I. Vals. for the sp. susceptibilities of dil. solid solutions of Ag, Au, Al, Ti, Zr, Si, Sn, Pb, V, As, Sb, Cr, Mo, W, Mn, Ru, Pd, and Pt are recorded for various temp. above the Curie point. The Curie point (0) and Curie const. (c) are calc. for each alloy. Deviations from the Curie–Weiss law are observed, due to a superimposed paramagnetism (a), which is independent of temp.

**II. Theoretical.** The variation of c with concn. of added metal, considered in relation to the results of Sadron (A., 1932, 679) for saturation magnetisation below 0, shows that in passing from the ferromagnetic to the paramagnetic state, there is no change in the no. of electrons (0.61 per Ni atom) responsible for the magnetic properties. The superimposed paramagnetism  $\alpha$  is due to the antiparallel arrangement of added atoms in the Ni lattice. The energy of interaction between magnetic atoms is discussed, and shown to depend only on the distance between their magnetic layers. L. J. J.

**Photo-electric effect of metallic alloys.** I. L. BELLADEN and G. GALLIANO (Annali Chim. Appl., 1936, 26, 30–34).—The photo-electric sensitivity (reciprocal of time required to produce unit charge on the electrometer, as compared with Cu) of Cu–Sn alloys has been measured in a new form of apparatus permitting the simultaneous examination of four samples; when plotted against Sn content the photo-electric sensitivity gives a graph with singular points at  $\text{Cu}_4\text{Sn}$ ,  $\text{Cu}_3\text{Sn}$ , and  $\text{Cu}_3\text{Sn}_2$ . E. W. W.

**Laws of valency electron concentration in binary intermetallic alloys.** H. PERLITZ (Acta Comm. Univ. Tartu., 1933, A, 24, No. 2, 16 pp.; cf. A., 1934, 22).—The Westgren and Hume-Rothery rule applies to  $\beta$ -,  $\gamma$ -, and  $\epsilon$ -alloys, the vals. of the ratio of the no. of valency electrons to the no. of atoms being 3:2, 21:13, and 7:4, respectively. A necessary condition for the existence of these structures is that one of the metals should contribute  $\leq 2$ , and the other  $\geq 1$ , valency electrons to the lattice structure. Various examples are discussed. CH. ABS. (e)

**Formation of spherical eutectic inclusions in alloys.** W. GELLER (Metallwirts., 1936, 15, 141–142).—Spherical eutectic inclusions have been observed in several Fe and Al alloys. The conditions for their formation are a narrow freezing range and rapid cooling just above the solidus. C. E. H.

**The system Mg–Cu–Al, particularly across the section  $\text{MgCu}_2$ – $\text{MgAl}_2$ .** F. LAYES and H. WITTE (Metallwirts., 1936, 15, 15–22).—Cu may be replaced by Al in  $\text{MgCu}_2$  without change of cryst. structure up to approx. 35%  $\text{MgAl}_2$ . With higher  $\text{MgAl}_2$  contents, hexagonal phases appear, but there are no definite limits of stability for the various structures. For the Al corner of the system previous results are not fully confirmed. Two compounds,  $\text{Mg}_2\text{Cu}_2\text{Al}_3$  and  $\text{Mg}_3\text{Cu}_7\text{Al}_{10}$ , are reported. C. E. H.

**System iron–aluminium–carbon.** R. VOGEL and H. MADER (Arch. Eisenhüttenw., 1935–1936, 9, 333–340).—The system contains six primary crystal phases:  $\alpha$ -Fe containing Al and Fe, ternary  $\gamma$ -Fe, graphite, ternary  $\epsilon$  ( $\text{FeAl}$ ) $_n$ , ternary  $\delta$  ( $\text{FeAl}_3$ ) $_n$ , and  $\text{Al}_4\text{C}_3$ . There are four 4-phase equilibria during solidification, viz., (1) liquid (Fe 83.1, Al 14.5%) +  $\alpha$  (Fe 85.1, Al 14.8%) +  $\gamma$  (Fe 91.7, Al 7.5%)  $\rightleftharpoons$   $\epsilon$  (Fe 85.2, Al 13%) at  $1335^\circ$ ; (2) liquid (Fe 83.35, Al 13.5%) +  $\gamma$  (Fe 90.3, Al 7.2%)  $\rightleftharpoons$   $\epsilon$  (Fe 83.5, Al 13%) + graphite at  $1132^\circ$ ; (3) liquid (Fe 56.7, Al 43%) +  $\delta$  (Fe 54.8, Al 45%)  $\rightleftharpoons$   $\epsilon$  (Fe 55.8, Al 44%) +  $\text{Al}_4\text{C}_3$  at  $1135^\circ$ ; (4) liquid (Fe 69.92, Al 29%)  $\rightleftharpoons$   $\epsilon$  (Fe 70.65, Al 29%) + graphite +  $\text{Al}_4\text{C}_3$  at  $1120^\circ$ . In the solid state three points of 4-phase equilibria exist, thus (5)  $\epsilon$  (Fe 71.7, Al 28%) +  $\text{Al}_4\text{C}_3$   $\rightleftharpoons$   $\delta$  (Fe 58.8, Al 41%) + graphite at  $1115^\circ$ ; (6)  $\epsilon$  (Fe 80, Al 17.5%) +  $\gamma$  (Fe 92.5, Al 6.9%)  $\rightleftharpoons$   $\alpha$  (Fe 92.3, Al 7.6%) + graphite at  $1111^\circ$ ; (7)  $\epsilon$  (Fe 72.85, Al 27%) + graphite  $\rightleftharpoons$   $\alpha$  (Fe 91.45, Al 8.5%) +  $\delta$  (Fe 71.3, Al 28.5%) at  $1100^\circ$ . Addition of Al to Fe–C alloys lowers the ledeburite eutectic temp., raises the pearlite transformation temp., extends the pearlite field, and favours the pptn. of graphite. A. R. P.

**System iron–cobalt–cobalt silicide–iron silicide.** R. VOGEL and K. ROSENTHAL (Arch. Eisenhüttenw., 1935–1936, 9, 293–299).—Microscopic and thermal examination of the system shows that FeSi and CoSi form a continuous series of solid solutions with one another and that a ternary compound  $\text{FeCoSi}$  exists below  $980^\circ$ . In the Fe–Co– $\text{Co}_2\text{Si}$ – $\text{FeCoSi}$ –FeSi section there are five planes of 4-phase equilibria, viz., liquid +  $\alpha$   $\rightleftharpoons$   $\gamma$  + FeSi at  $1185^\circ$ , liquid +  $\text{Co}_2\text{Si}$  solid solution  $\rightleftharpoons$  ternary  $\alpha$ -Fe + ternary  $\alpha$ - $\text{Co}_2\text{Si}$  at  $1180^\circ$ , liquid  $\rightleftharpoons$  ternary  $\alpha$ -Fe + ternary

$\gamma$ -Fe+Co-rich solid solution at 1165° and liquid  $\rightleftharpoons$  ternary  $\beta$ -Co<sub>2</sub>Si solid solution+ternary  $\gamma$ -FeSi at 1170°; at 985°  $\alpha$ -Fe reacts with FeSi to form Fe<sub>3</sub>Si<sub>2</sub> and  $\gamma$ -Fe. The compounds Co<sub>2</sub>Si and FeCoSi form a continuous series of solid solutions and hence the 3-phase equilibria in the system Co<sub>2</sub>Si-CoSi merge into those of FeSi-FeCoSi. Diagrams for const. Fe-Co ratios from 8:1 to 1:13 and for the equilibria at 20° and 1160° together with photomicrographs are given. A. R. P.

Diffusion of carbon, silicon, and manganese in solid and liquid iron. M. PASCHKE and A. HAUTTMANN (Arch. Eisenhüttenw., 1935—1936, 9, 305—309).—The diffusion of C in solid Fe is given by  $\log D = 4.6248 - 7.95 \times 10^3/T$ , where  $T$  is abs. temp. The rate of diffusion of Mn into Fe at 1400° appears to be about 0.01 times that of C. The diffusion coeff. of Mn in liquid Fe at 1530° is 9.1 and at 1570° 8.7 sq. cm. per 24 hr.; that of Si at 1540° is 3.3 sq. cm. per 24 hr. A. R. P.

Structure of solid solutions of Fe<sub>2</sub>O<sub>3</sub> in Mn<sub>2</sub>O<sub>4</sub>. E. J. W. VERVEY and M. G. van BRUGGEN (Z. Krist., 1935, 92, 136—138).—The system Mn<sub>2</sub>O<sub>4</sub>-Fe<sub>2</sub>O<sub>3</sub> has been studied by powder photographs. B. W. R.

Piezometric researches. II. Mutual solubility of liquids. G. POPPE (Bull. Soc. chim. Belg., 1935, 44, 640—657; cf. A., 1935, 1314, 1457).—The crit. solution temp. and their variation with pressure have been determined for 36 binary mixtures, including 5 mixtures containing D<sub>2</sub>O. Replacement of H<sub>2</sub>O by D<sub>2</sub>O increases the range of incomplete miscibility. Glycerol and guaiacol are completely miscible, but small amounts of H<sub>2</sub>O cause separation. The salting-out action of KCl on  $\alpha$ -picoline-D<sub>2</sub>O mixtures is > with  $\alpha$ -picoline-H<sub>2</sub>O mixtures. J. W. S.

Comprehensive  $\log p-1/T$  diagram for binary system methylamine-water. W. MEHL [with FELSING and THOMAS] (Z. ges. Kälte-Ind., 1935, 42, 13—14; Chem. Zentr., 1935, i, 3021).—B.p.-concn.,  $\log p-1/T$ , and solubility-temp. data at 1 atm. are recorded. J. S. A.

Solubility relationships of 96% alcohol and glyceryl nitrate. D. A. COPEMAN (J. S. African Chem. Inst., 1936, 19, 17—18).—The miscibility has been studied between 15° and 40°. J. S. A.

Solubility of sulphur dioxide in sulphuric acid. J. MILBAUER (Bull. Soc. chim., 1936, [v], 3, 221—224).—Data are recorded for H<sub>2</sub>SO<sub>4</sub> ( $d$  1.824) at 23—237° and H<sub>2</sub>SO<sub>4</sub> ( $d$  1.53) at 25—100°. E. S. H.

Solubility and activity of the halogenates of some bivalent metals. Solubility and activity of (I) barium iodate and (II) lead iodate in water and in solutions of electrolytes. A. POLESSITSKI (Compt. rend. Acad. Sci. U.R.S.S., 1935, 4, 193—196, 197—200).—The solubility of Ba(IO<sub>3</sub>)<sub>2</sub> and of Pb(IO<sub>3</sub>)<sub>2</sub> in H<sub>2</sub>O between 0° and 100°, and the solubility and activity coeffs. at 25° in solutions containing KNO<sub>3</sub>, Cu(NO<sub>3</sub>)<sub>2</sub>, and KIO<sub>3</sub>, have been determined. R. S.

Salts of higher alkylsulphonic acids. R. M. REED and H. V. TARTAR (J. Amer. Chem. Soc.,

1936, 58, 322—332).—The solubilities of Ca, Mg, and Na alkylsulphonates ( $n$ -octyl,  $n$ -decyl, lauryl, myristyl, cetyl, and  $n$ -octadecyl) in H<sub>2</sub>O have been determined at 25° and 60°. Data for surface tension, interfacial tension against C<sub>6</sub>H<sub>6</sub>, and electrical conductivity of these solutions are recorded. The interfacial tension changes with time. The conductivity relations are analogous to those of soap solutions. E. S. H.

Solubility of arsenious oxide in aqueous solutions of certain halides of alkali metals and ammonium. E. JOSEFOWICZ (Rocz. Chem., 1935, 15, 460—467).—Solubility data are recorded at 25° for solutions of Li, Na, K, and NH<sub>4</sub> chlorides and bromides, and of KI and NaI. The existence of mol. compounds is said to be indicated. R. T.

Influence of NH<sub>4</sub>Cl on the solubility of CoHg(SCN)<sub>4</sub>. B. V. J. CUVELIER (Z. anorg. Chem., 1936, 226, 197—200).—By a method previously described (A., 1934, 1323), the solubility has been determined at temp. up to 80° and concns. of aq. NH<sub>4</sub>Cl up to 3*N*. The solubility increases with temp., and more rapidly for higher [NH<sub>4</sub>Cl]. M. S. B.

Solubility of benzoic and salicylic acids in mixtures of organic solvents. P. G. DESAI and A. M. PATEL (J. Indian Chem. Soc., 1935, 12, 808—812).—In mixtures of non-polar solvents (C<sub>6</sub>H<sub>6</sub> with PhMe, xylene, or hexane) the solubility-composition curves are straight lines. The solubility in mixtures of polar and non-polar solvents (CHCl<sub>3</sub> or COMe<sub>2</sub> with aromatic hydrocarbons) gives a curve which is concave or convex to the composition axis; in mixtures of C<sub>6</sub>H<sub>6</sub> with MeOH, EtOH, Pr<sup>n</sup>OH, or Bu<sup>n</sup>OH the solubility curve passes through a max. E. S. H.

Fractionation of barium salts containing radium. (MME.) B. E. MARQUES (J. Chim. phys., 1936, 33, 1—40; cf. A., 1934, 22, 343, 726).—The distribution of Ra between solid and liquid phases (cf. A., 1925, ii, 381) is found to be the same whether the solid phase is obtained by crystallisation of supersaturated solutions, cooling of saturated solutions, or pptn., and whatever be the anion present (Br<sup>-</sup>, Cl<sup>-</sup>, NO<sub>3</sub><sup>-</sup>, SO<sub>4</sub><sup>2-</sup>, or CO<sub>3</sub><sup>2-</sup>). J. W. S.

Adsorption isotherms. Critical conditions. R. H. FOWLER (Proc. Camb. Phil. Soc., 1936, 32, 144—151).—Mathematical. A. J. M.

Chemisorption on charcoal. VII. Adsorption of water vapour. C. G. LAWSON (Trans. Faraday Soc., 1936, 32, 473—478; cf. A., 1935, 27).—Earlier work has been repeated and extended using a sorption balance designed to measure adsorption of H<sub>2</sub>O on charcoal covered with various surface oxides, small quantities of desorbed gases being continuously removed. Isotherms are given for charcoals activated at different temp. The mean time of sojourn of H<sub>2</sub>O mols. on the surface is increased in the presence of the surface oxide formed at about 400°, but decreased by the oxide formed at high temp. The extent of hysteresis has been examined for two charcoals. Chemisorption is not observed with ash-free charcoal. Adsorption on graphite is of the same type and cannot be attributed to capillary condensation. O. J. W.

**Adsorption isotherm of heavy water on charcoal.** A. KING and C. G. LAWSON (Trans. Faraday Soc., 1936, 32, 478—481).—The isotherms of  $D_2O$  and of  $H_2O$  on outgassed charcoal at  $110^\circ$  are shown to be very similar. No special theoretical significance can be attached to the slightly greater adsorption of  $D_2O$ . O. J. W.

**Sorption of bromine and iodine by activated charcoal.** L. H. REYERSON and A. E. CAMERON (J. Physical Chem., 1936, 40, 233—237; cf. A., 1935, 696).—Equilibrium data for the sorption of Br by activated C at  $58^\circ$ ,  $98.1^\circ$ ,  $137.6^\circ$ , and  $178.4^\circ$  and of I at  $178.4^\circ$  and  $218.8^\circ$ , and also rates of adsorption and desorption of Br and I at  $137.6^\circ$ , are given. M. S. B.

**Dissociation equilibrium of hydrogen and its adsorption on tungsten.** J. K. ROBERTS (Proc. Camb. Phil. Soc., 1936, 32, 152—157).—The application of a formula derived from a kinetic treatment of the process of desorption in which a const. evaporation coeff. for desorbing particles is assumed (this vol., 155) leads to vals. for the rate of evaporation of H from W which do not agree with the dissociation equilibrium, if the results of Langmuir *et al.* (A., 1931, 782) are used. The nature of the surface reactions occurring is discussed. It would appear that measurements of the rate of removal of the adsorbed film of  $O_2$  on W do not afford a measure of the rate of evaporation of O atoms, or that it is not possible to obtain a general first approximation formula for the rate of evaporation of adsorbed atoms in terms of the heat of adsorption. A. J. M.

**Sorption of hydrogen and deuterium by copper and palladium.** I. Behaviour of copper and copper oxides. II. Sorption by palladium and diffusion through copper. H. W. MELVILLE and E. K. RIDEAL (Proc. Roy. Soc., 1935, A, 153, 77—88, 89—103).—I. CuO is reduced by at. H and D at  $20^\circ$  with the same velocity. It is more rapidly reduced by mol.  $H_2$  than  $D_2$  at  $156$ — $269^\circ$ , the difference in energy of activation being  $0.4$  kg.-cal.  $H_2$  and  $D_2$  are sorbed by, and desorbed from, Cu with the same velocity at  $71$ — $200^\circ$ ; at higher temp., however,  $H_2$  is sorbed slightly more rapidly. The results indicate that the process of activated diffusion of  $H_2$  into Cu is composite, including a true activated diffusion. There is also another process independent of the nature of the two gases which determines the rate at low temp.

II.  $H_2$  diffuses more rapidly than does  $D_2$  through Pd and through thin films of Cu and Ni supported on Pd, at temp. from  $150^\circ$  to  $350^\circ$  and pressures  $1$ — $200$  mm. In Cu it has been shown by using composite films, Cu-Pd-Cu and Pd-Cu-Pd, that the rate-determining step is not due to any process connected with the gas-metal interface.  $H_2$  is more sol. than  $D_2$  in Pd, the difference in diffusion velocities being due partly to this, and partly to the greater mobility of  $H_2$  in Pd. Potential barriers have been constructed from diffusion and solubility data. L. L. B.

**Active oxides. XCVIII. Changes in sorptive power of mixtures of calcium oxide with ferric oxide, and of calcium oxide and beryllium oxide with chromic oxide, during chemical combin-**

ation. J. HAMPEL (Z. anorg. Chem., 1936, 226, 132—140).—The oxide mixtures were prepared by the method previously described (A., 1934, 490; 1935, 440), heated at various temp. up to  $1000^\circ$ , and the sorptive power ( $s$ ) measured for Congo-red, acid fuchsin, and eosin (cf. A., 1935, 930). The  $s$ -temp. curves fall with rise in the temp. at which the preliminary heating takes place, but there are many irregularities resulting in max. and min. and points of inflexion. The curves are compared with those for the variation of other physical properties with temp. M. S. B.

**Sorption of gases and vapours by aerosol particles.** A. KRASSILCHIKOV (Kolloid-Z., 1936, 74, 138—147).—The concn. of a sorbable gas or vapour is determined in the presence or absence of aerosol particles by measuring its diffusion into a long narrow tube, the vol. of which is small compared with that of the experimental vessel with which it is connected. By this means the sorption of Br vapour by paraffin oil, resin, and  $NH_4Cl$  particles has been determined. The sorption isotherms for the oil indicate dissolution rather than adsorption. With resin, bromination occurs.  $NH_4Cl$  shows purely surface effects, and the adsorption can be expressed by Langmuir's equation. With increasing [Br] the adsorption per sq. cm. reaches a max. and thereafter decreases, apparently owing to rapid coagulation and desorption at high [Br]. F. L. U.

**Adsorption and diffusion in zeolite crystals.** A. TISELIUS (J. Physical Chem., 1936, 40, 223—232).—The adsorption of  $NH_3$  by analcite follows the Langmuir law and the heat of adsorption is const. over a wide range, indicating a lack of interaction between adsorbed mols. When  $NH_3$  is adsorbed by a Cu chabasite, prepared by cationic exchange in aq.  $CuSO_4$ , the crystal has the absorption spectrum of a solution containing  $CuNH_4$  ions, showing that co-ordination valencies play a part in adsorption. The diffusion const. of  $H_2O$  in a dehydrated heulandite crystal has been determined by following, with the polarising microscope, the changes in double refraction during adsorption of  $H_2O$ . The diffusion is anisotropic. It follows the ordinary diffusion laws of solutions for small concn. differences, but for larger is largely dependent on concn. Since concn. at the surface remains const. and equal to the saturation val., during adsorption, diffusion in the crystal must be the rate-determining factor. M. S. B.

**Adsorption of electrolytes on crystal surfaces.** (MISS) L. DE BROUCKÈRE (Chem. Weekblad, 1936, 33, 104—109).—A reply to criticism by Kolthoff (A., 1934, 727; cf. A., 1933, 457; 1934, 359). D. R. D.

**Adsorption at crystal-solution interfaces. IX. Concentration of foreign substances in solution relative to the quantity adsorbed by the host crystal.** W. G. FRANCE and (MISS) P. P. DAVIS (J. Physical Chem., 1936, 40, 177—185).—There is no relation between the no. of colloidal particles of dye in solution and the amount of dye adsorbed by a given host crystal. Crystals containing adsorbed impurities have the same lattice consts. as the pure crystals. The dichroism frequently observed in

crystals containing adsorbed dye appears to be due to orientation of the dye mols. with respect to the adsorbing surface. The colour effects observed, when crystals of  $\text{NH}_4$  alum containing Pontamine Sky Blue 6B are examined under a polarising microscope, indicate that the long axes of the adsorbed dye mols. are probably perpendicular to the cube faces of the crystals. The data for the adsorption of dye by alum and nitrate crystals are not in accordance with either the Langmuir or adsorption isotherm equations, but are reproduced over nearly the whole range by  $a = kc^{1/n} - k'c^{-1/n}$ , where  $a$  is the mol. ratio of impurity to host crystal and  $c$  the ratio in the solution. The cause of the failure of the adsorption curves to pass through the origin is discussed. M. S. B.

**Adsorption of anions by precipitated calcium oxalate.** T. P. CHAO, D. K. WU, W. P. CHIANG, and T. F. CHAO (J. Chinese Chem. Soc., 1936, 4, 6-19).—The adsorption of anions by  $\text{CaC}_2\text{O}_4$  occurs in the order  $\text{Fe}(\text{CN})_6''' > \text{NO}_3' > \text{Fe}(\text{CN})_6''' > \text{SO}_4''' > \text{NO}_2' > \text{ClO}_3' > \text{Cl}' > \text{Br}' > \text{CNS}'$ , i.e., except for  $\text{NO}_3'$  in the order of decreasing ionic charge. The order is slightly different from that with  $\text{BaSO}_4$  (cf. this vol., 154) and adsorption is much less. Adsorption is usually in the same order as the solubility of the Ca salts; the different behaviour of the univalent anions indicates that a sp. factor is involved. Special methods for the analysis of adsorbed ions are described. R. S. B.

[Theory of coprecipitation.] L. DE BROUCKÈRE (Bull. Soc. chim. Belg., 1935, 44, 625-636; cf. A., 1934, 359).—A reply to Kolthoff (*ibid.*, 727).

**Sorption of lime by cellulose and wood.** G. L. LABOQUE and O. MAASS (Canad. J. Res., 1935, 13, B, 380-383).—The adsorption of  $\text{CaO}$  is  $>$  that of  $\text{NaOH}$ . Considerable time is required for saturation adsorption to take place. The adsorption on similar woods is the same but much  $>$  that on cotton cellulose. E. E. A.

**"Apparent" and "true" adsorption functions.** K. S. G. DOSS and B. S. RAO (J. Mysore Univ., 1935, 8, 49-61).—Adsorption on  $\text{SiO}_2$  gel from  $\text{C}_5\text{H}_5\text{N}-\text{H}_2\text{O}$  and  $\text{CCl}_4-\text{H}_2\text{O}$  mixtures is discussed. C. W. G.

**Reversible adsorption in the surface of soap solutions.** J. W. MCBAIN and D. A. WILSON (J. Amer. Chem. Soc., 1936, 58, 379-380).—The fact that several hr. are required to complete the adsorption of solutes at the surface of their solutions throws doubt on many recorded surface tension measurements. E. S. H.

**Sorption of acid sodium oleate.** R. F. NICKERSON (J. Physical Chem., 1936, 40, 277-286).—The kinetics of the sorption at the interface between aq. Na oleate (I) and hydrocarbon oils—both aliphatic and aromatic—have been studied by a method previously employed (A., 1932, 803). Relative sorption potentials are tabulated. The results support the view that energy transfers in colloid systems involve chemical and electrochemical processes. In the case of the systems considered, free interfacial energy is stored as electrochemical potential through the ionisation of  $\text{H}_2\text{O}$  as a result of the hydrolysis of

(I) when acid (I) is adsorbed at the interface. The causes of the failure of Gibbs' adsorption equation are discussed. M. S. B.

**Direct measurement of absolute amount of adsorption in liquid surfaces.** T. F. FORD and J. W. MCBAIN (J. Amer. Chem. Soc., 1936, 58, 378).—An interferometer method is described. E. S. H.

**Kinetics of sorption.** A. V. LYKOV (Kolloid-Z., 1936, 74, 179-183).—The distribution of temp. in a sphere of cellulose during sorption of  $\text{H}_2\text{O}$  vapour has been determined. Curves showing change of  $\text{H}_2\text{O}$  content with time for different temp. are given. F. L. U.

**Adsorption and pyknometry.** P. G. NUTTING (J. Washington Acad. Sci., 1936, 26, 1-6).—A review of technique and errors in pyknetric determinations of  $d$  for highly adsorptive clays and similar materials. H. J. E.

**Adsorption by diatomaceous filters.** E. J. HOAGLAND and J. E. RUTZLER, jun. (J. Physical Chem., 1936, 40, 215-221).—A comparison of the adsorption of different liquids or solutions by Berkeley "N" diatomaceous candles has been made by comparing the rates of flow of air through candles wetted by the different liquids. Different filters of the same rating show great variations in behaviour, probably because of different degrees of crushing of the diatoms during manufacture. Salts are adsorbed to a variable extent and  $\text{MeOH}$ ,  $\text{EtOH}$ , and  $\text{CCl}_4$  are less readily adsorbed than  $\text{H}_2\text{O}$ . The significance of these results in the methods of pore size determination is discussed. M. S. B.

**Binding of water by inorganic materials.** I. R. BULL (Angew. Chem., 1936, 49, 145-153).—Bound  $\text{H}_2\text{O}$  is classified as discontinuous or continuous according as dehydration does or does not produce a new phase. Discontinuously bound  $\text{H}_2\text{O}$  may be determined by treating the solid with dioxan (I), the  $\text{H}_2\text{O}$  removed being calc. from the change in dielectric const. of (I). With varying amounts of material and (I), a stepped dehydration curve is obtained. Attainment of equilibrium in the removal of hydration  $\text{H}_2\text{O}$  is slow; mechanically held  $\text{H}_2\text{O}$  is rapidly extracted and may be so determined. Adsorbed  $\text{H}_2\text{O}$  is determined by extraction with a small proportion of moist (I). J. S. A.

**Surface tension of calcium amalgam.** L. CONVERS (Compt. rend., 1936, 202, 289-291; cf. this vol., 142).—Measurements in vac. by the drop-wt. method with amalgams containing 0-0.0033% of Ca are described. The measurements are affected by traces of  $\text{O}_2$ . H. J. E.

**"Pockeling" of freshly swept surfaces of solutions.** D. A. WILSON and T. F. FORD (Nature, 1936, 137, 235-236).—The sudden appearance and expansion of circular patches on fresh surfaces of dil. solutions of surface-active material are described and explained. Drastic sweeping eliminates this effect. L. S. T.

**Composition of fatty acid films on water containing calcium or barium salts.** I. LANGMUIR and V. J. SCHAEFER (J. Amer. Chem. Soc., 1936, 58, 284-287).—Technique for the removal and analysis of

unimol. films on  $H_2O$  is described. In presence of  $Ca^{++}$  or  $Ba^{++}$  (about  $10^{-4}M$ ) the films formed by stearic acid are nearly pure neutral soaps when the solution has  $p_H$  11, and free fatty acid films at  $p_H$  3; they are half converted into neutral soaps at  $p_H$  5.1 for  $Ca^{++}$  and  $p_H$  6.6 for  $Ba^{++}$ . The presence of  $Ca$  or  $Ba$  increases the rigidity of the films and affects the ease with which multimol. films can be formed on metal or glass.

E. S. H.

**Action of potassium *n*-amylxanthate on chalcocite.** A. M. GAUDIN and R. SCHUHMAN, jun. (J. Physical Chem., 1936, 40, 257—275).—The results show that the collecting action of xanthates in the flotation of chalcocite (I) is due to an oriented adsorbed film formed by the reaction of xanthate ions with impurities, produced by grinding, on the surface of the mineral, and subsequent reaction with the  $Cu$  of the (I) to give  $Cu^I$  xanthate. The film cannot be leached off by ordinary solvents until sufficient of the xanthates is formed to give a complete unimol. film. Only a relatively small fraction of a unimol. film of uncatchable product, however, is necessary for efficient flotation. Malachite (II) also abstracts xanthates from the aq.  $K$  *n*-amylxanthate, but the film is removed by leaching and the (II) is non-floatable. Adsorption-reaction curves, calc. on a kinetic basis, are in good agreement with the experimental results for (I).

M. S. B.

**Stream potentials and d.c. surface conductivities in small capillaries.** H. L. WHITE, (Miss) B. MONAGHAN, and F. URBAN (J. Physical Chem., 1936, 40, 207—214).—The streaming potential,  $E/P$ , of glass capillaries diminishes with decreasing capillary diameter, due mainly to increasing sp. conductance as a result of the relatively larger surface conductance.  $E/P$  also decreases with time, probably due to a decrease in  $\zeta$ . The normal d.c. sp. surface conductance of  $0.0001M$ - $KCl$  at a Pyrex surface is approx.  $1.5 \times 10^{-9}$  mho, and of  $0.0005M$ - $KCl$   $1.7 \times 10^{-9}$  mho (cf. A., 1932, 699). Variations in  $\zeta$  for a given capillary, as shown by variations in  $E/P$ , are also reflected in the sp. surface conductance.

M. S. B.

**Influence of size, symmetry, and concentration of ions and dipoles on the dielectric potential of the solution-dielectric interface.** B. KAMIENSKI (Bull. Acad. Polonaise, 1935, A, 309—318).—It is argued that (a) small ions have little effect on the dielectric potential at the interface solution-dielectric when the dielectric const. is small, (b)  $H_2O$  dipoles are preferentially adsorbed at the solution-air interface, and (c) large mols. and ions of weak electrolytes displace  $H_2O$  dipoles at the interface. These conclusions are supported by the dielectric potentials of quinine solutions in relation to  $p_H$ , and by previous data.

T. G. P.

**Simplified dynamical method of measuring dielectric potentials at the solution-air interface.** B. KAMIENSKI and W. GOSLAWSKI (Bull. Acad. Polonaise, 1935, A, 319—322).—The reference electrode is a vertical  $Cu$  tube moistened on the inside with aq.  $CuSO_4$ , through the centre of which the solution under investigation flows in a fine stream.

T. G. P.

**Influence of hydrogen ions on the dielectric potential of the stereoisomerides quinine and quinidine.** B. KAMIENSKI and W. GOSLAWSKI (Bull. Acad. Polonaise, 1935, A, 323—326).—Dielectric potentials at the solution-air interface of quinine and quinidine solutions have been measured at  $p_H$  2—9.  $0.01M$ -Quinidine is more sensitive to  $p_H$  than  $0.01M$ -quinine; at lower concn. the quinine solutions are the more sensitive.

T. G. P.

**Behaviour of water held in fine-pored media.** B. H. WILSDON, D. G. R. BONNELL, and (Miss) M. E. NOTTAGE (Trans. Faraday Soc., 1936, 32, 570).—Errors in a paper previously published (A., 1935, 1316) are corr.

F. L. U.

**Influence of an inert solid phase on the f.p. of water and dilute aqueous solutions. II. Starch-water.** A. V. RAKOVSKI, D. N. TARASENKOV, and A. V. KOMANDIN (J. Gen. Chem. Russ., 1935, 5, 1441—1444; cf. this vol., 156).— $H_2O$  adsorbed on starch (up to 33%) does not freeze at  $-180^\circ$ ;  $H_2O$  in excess of 33% freezes at  $0^\circ$  to  $-3.16^\circ$  according to the ratio of starch surface to excess of  $H_2O$ . The presence of low concns. of solutes does not specifically affect the results. The action of surface forces is not apparent at a distance of  $> 10,000$  mol. diameters of  $H_2O$ .

R. T.

**Microcataphoresis. I. Technique.** H. C. BROWN and J. C. BROOM (Proc. Roy. Soc., 1936, B, 119, 231—244).—An experimental cell and important details of technique are described. Komagata's correction of the calculation of the stationary layer in cells with a width/depth ratio of  $< 20$  is verified.

F. A. A.

**Rate of diffusion through membranes.** S. MIYAMOTO (Kolloid-Z., 1936, 74, 194—196; cf. A., 1933, 233).—Theoretical. Under certain conditions, which are specified, the expression deduced reduces to  $\lambda\sqrt{M} = \text{const.}$  ( $\lambda$ =dialysis const.,  $M$ =mol. wt. of solute).

F. L. U.

**Diffusion of water vapour through membranes of cellulose acetate and cellulose nitrate.** S. VOSNESSENSKI and L. M. DUBNIKOV (Kolloid-Z., 1936, 74, 183—194).—The rate of diffusion of  $H_2O$  vapour through membranes of cellulose acetate (Ac no. = 56) and nitrate has been measured under varying conditions of v.p., temp., thickness and character of membrane, and is related in a simple manner to the first three variables (expressions given). Membranes formed by evaporation of a solution in contact with a polished surface are less permeable when vapour enters at the "free" (matt) surface than for the reverse direction.

F. L. U.

**Ebullioscopic constants.** C. DUVAL (Compt. rend., 1936, 202, 660—662).—It is shown that Trouton's rule may be utilised in the calculation of ebullioscopic consts.

L. J. J.

**Refractions of electrolyte solutions. IV. Complete refraction curve of potassium chloride.** A. E. BRODSKI and N. S. FILIPPOVA (Z. physikal. Chem., 1936, B, 31, 227—236; cf. A., 1934, 131).—The refraction curve has been determined from  $0.001$  to  $1.4N$  and agrees with published data for

conc. solutions, and with the conclusions previously reached.

R. C.

**Dielectric constants of dilute solutions of strong electrolytes at various temperatures.** M. JEZEWSKI, M. WIERZBICKI, and J. KAMECKI (Bull. Acad. Polonaise, 1935, A, 417—429).—The dielectric consts. ( $\epsilon$ ) of solutions of NaCl, KCl,  $\text{MgSO}_4$ ,  $\text{CuSO}_4$ , and  $\text{Ba}_2\text{Fe}(\text{CN})_6$  at  $0^\circ$ ,  $10^\circ$ ,  $18^\circ$ , and  $25^\circ$ , determined by a resonance method, agree with the Debye-Falkenhagen theory at low concns. but in the more conc. solutions  $\epsilon$  is  $<$  the theoretical val. This is probably due to orientation of dipoles in the strong ionic fields at higher concn. The relaxation times are also calc.

A. J. M.

**Dielectric constants of solutions of electrolytes.** G. FISCHER and W. D. SCHAEFFELD (Ann. Physik, 1936, [v], 25, 450—466; cf. Orthmann, A., 1931, 786).—The variation of dielectric const. ( $\epsilon$ ) with concn. ( $c$ ) in aq. solutions of NaCl, NaI,  $\text{NaNO}_3$ ,  $\text{KNO}_3$ ,  $\text{AgNO}_3$ , HCl,  $\text{HNO}_3$ , and  $\text{H}_2\text{SO}_4$  has been determined. There is a decrease in  $\epsilon$  with increasing  $c$ , expressed by a formula of the type,  $\epsilon = \epsilon_0(1 + ac^b - bc)$ , where  $a$  and  $b$  are consts. For NaI and NaCl,  $a = 0.095$ ,  $b = 1.45$ . For  $c < 0.01$  g.-mol. per litre, the results accord with the Debye-Falkenhagen theory,  $a$  being 0.047 and  $b$ , 1.0 over this concn. range. For  $\text{NaNO}_3$ ,  $\text{KNO}_3$ , and  $\text{AgNO}_3$ ,  $a = 0.051$ ,  $b = 1.1$ . For HCl and  $\text{HNO}_3$  ( $c < 0.03N$ ),  $a = 0.55$ ,  $b = 8$ , and for  $\text{H}_2\text{SO}_4$ ,  $a = 0.2$ ,  $b = 5$ .

A. J. M.

**Optical behaviour of dissolved ions and its significance for the structure of solutions of electrolytes. II. Optical rotation of phenylbenzylmethylpropylammonium ion.** G. KORTUM (Z. physikal. Chem., 1935, B, 31, 137—151; cf. this vol., 285).—Some salts increase the sp. rotation of the above ion, whilst others depress it, but there is no simple relation between the magnitude and sign of the effect and the charge, size, or polarisability of the foreign anion. It is inferred that the optical properties of ions are affected by solvation forces far more than by Coulomb forces. In general the rotation is influenced by change in solvent much more than by the presence of salts. The results obtained agree with the view that in their aq. solutions at low and moderate concns. strong electrolytes are completely dissociated into fully solvated ions.

R. C.

**Faraday effect of strong electrolytes in aqueous solutions. III.** A. OKAZAKI (Mem. Ryojun Coll. Eng., 1935, 8, 1—29; cf. A., 1935, 1318).—Data at  $29^\circ$  are recorded for aq.  $\text{Sr}(\text{NO}_3)_2$ ,  $\text{Zn}(\text{NO}_3)_2$ , and  $\text{Pb}(\text{NO}_3)_2$  with  $\lambda$  3514 Å., and for aq.  $\text{MgCl}_2$ ,  $\text{CaCl}_2$ ,  $\text{SrCl}_2$ ,  $\text{BaCl}_2$ ,  $\text{ZnCl}_2$ ,  $\text{CdCl}_2$ ,  $\text{AlCl}_3$ ,  $\text{CaBr}_2$ ,  $\text{BaBr}_2$ ,  $\text{H}_2\text{SO}_4$ ,  $\text{MgSO}_4$ ,  $\text{ZnSO}_4$ ,  $\text{CdSO}_4$ , and  $(\text{NH}_4)_2\text{SO}_4$  with  $\lambda$  3441 Å. For most electrolytes  $[z]$  is independent of, or decreases with, increasing concn. For  $\text{H}_2\text{SO}_4$  and  $\text{Zn}(\text{NO}_3)_2$  it increases with concn.

CH. ABS. (e)

**Ionic susceptibilities of rubidium from its different salts in the solid and in the dissolved state.** S. S. BHATNAGAR, M. B. NEVGI, and M. L. KHANNA (J. Indian Chem. Soc., 1935, 12, 799—807).—Data for  $\text{RbCl}$ ,  $\text{RbBr}$ ,  $\text{RbI}$ , and  $\text{Rb}_2\text{SO}_4$  have been obtained at different temp. The ionic

diamagnetism of  $\text{Rb}^+$  is the same in the solid and dissolved states. The calc. ionic radius is  $1.875 \times 10^{-8}$  cm.

E. S. H.

**Crystalline structure and physicochemical properties in the colloidal state.** T. S. BHATNAGAR (Current Sci., 1936, 4, 570—571).—A review.

**Magnetic properties of colloidal powders of metallic elements.** S. R. RAO (Current Sci., 1936, 4, 572—576).—A review.

**Disperse gases. I. Thermodynamics and preparation.** R. AUERBACH (Kolloid-Z., 1936, 74, 129—138).—Relations between bubble size in gas-liquid systems, and surface tension, density, and external pressure are discussed. In preparing systems of varying dispersity gas is dispersed in a liquid by mechanical means while subject to a low total or partial pressure. Restoration of the system to atm. pressure then yields a dispersion of the required fineness.

F. L. U.

**Diffusion coefficients and velocities of fall in air of atmospheric condensation nuclei.** J. J. NOLAN and V. H. GUERRINI (Proc. Roy. Irish Acad., 1936, 43, A, 5—24).—Methods for the determination of the diffusion coeff.  $D$  and the velocity of fall in air  $V_f$  of atm. condensation nuclei are described. For Dublin air  $D = 18 \times 10^{-6}$  sq. cm. per sec. and  $V_f = 7.5 \times 10^{-5}$  cm. per sec. The mass calc. from these vals. is  $1.68 \times 10^{-16}$  g. and the radius  $2.85 \times 10^{-6}$  cm. In stored air there is a progressive increase in size, but the wt. of the nucleus decreases with time. Comparison of the nuclei in town and country air suggests that when nuclei are fresh from the place of production they are small and numerous, but as the source becomes more remote the concn. falls and the size increases whilst  $D$  diminishes. The relation between concn. and size of nuclei may help to explain the anomalies in the equilibrium between small ions and nuclei.

M. S. B.

**Emulsification by ultrasonic waves.** C. BONDY and K. SÖLLNER (Trans. Faraday Soc., 1936, 32, 556—567; cf. A., 1935, 820).—The influence of various experimental conditions on the extent of emulsification and the degree of dispersion of emulsions produced by ultrasonic waves has been investigated in the systems  $\text{H}_2\text{O}$ +org. liquid,  $\text{Hg}$ +aq. solution, and  $\text{Hg}$ +org. liquid. In the first group the concn. of the emulsion reached in a given time increases with increase of the energy of radiation. The degree of dispersion is the greater, the smaller is the energy and the shorter the time of radiation. Prolonged irradiation always leads to progressive coarsening of an emulsion already formed. The  $\text{Hg}$  systems behave differently, as is to be expected from the different mechanism involved in their emulsification.

F. L. U.

**Production of highly disperse states.** B. CLAUS (Z. tech. Physik, 1935, 16, 80—82; Chem. Zentr., 1935, i, 2958).—When the cathode is subjected to the action of supersonic radiation in the electrolysis of metallic salt solutions coherent deposition of metal is inhibited, and highly disperse metal sols are formed. Factors influencing the degree of dispersion have been investigated.

J. S. A.

**Perchlorates as solvents for cellulose and its derivatives.** (MME.) A. DOBRY (Bull. Soc. chim., 1936, [v], 3, 312—318).—Cellulose acetate dissolves in saturated aq. solutions of Ca, Mg, Cu, and Zn perchlorates in the cold, and in Li and Ag perchlorates and basic Pb perchlorate when hot.  $\text{Mg}(\text{ClO}_4)_2$  is the most active. The dissolution is not accompanied by chemical degradation. Cellulose nitrates and butyrate and benzylcellulose are insol. in these salt solutions. Cellulose dissolves practically unchanged in basic Be perchlorate solutions. E. S. H.

**Viscosity of suspensions and solutions. I. Viscosity of suspensions.** E. GUTH. **II. Theory of electro-viscosity.** W. KRASNY-ERGEN (Kolloid-Z., 1936, 74, 147—172, 172—178).—I. Introductory and mathematical.

**II. Mathematical.** Von Smoluchowski's formula is shown to be an approximation formula suitable for relatively good conductors. It is not valid for non-conducting liquids. F. L. U.

**Viscosity and lyotropic numbers.** J. H. C. MERCKEL (Rec. trav. chim., 1936, 55, 82—84).—A reply to Bruins (this vol., 285). D. C. J.

**Viscosity of organic colloids.** W. PHILIPPOFF and K. HESS (Z. physikal. Chem., 1936, B, 31, 237—255; cf. A., 1935, 31, 822).—The determination and variation of the consts. of the flow curve (cf. *ibid.*, 692) are described. For various solutions at consens.,  $c$ , of 0.01—30% the variation of  $\eta_0$  with  $c$  is given by  $\eta_{rel} = (1 + c/c_0)^8$ , where  $c_0$  is a const. for a given solvent and solute. For solutions of cellulose nitrate (I) in  $\text{BuOAc}$   $\eta_{\infty}$  is  $\propto c$ . Chemical and mechanical treatment of the solute, change of temp., and variation of the solvent and particle size distribution shift the  $\eta_0$ - $c$  curve along the  $c$  axis without altering its form, i.e., the above equation remains valid, with variation in  $c_0$ . With rise in temp.  $\eta_{rel}$  usually falls. For mixed solutions of several varieties of (I)  $\eta = (1 + \sum c_i/c_{0i})^8$ , where  $c_i$  are the consens. of the components in the mixture and  $c_{0i}$  the vals. of  $c_0$  for the components. It appears that  $\eta_0$  is a function of the space demand of the solute only in the sense that the flow of the solvent is impeded by the vol. of the solute. R. C.

**Lyophilic colloids. II. Interaction of agar fractions.** A. A. MOROZOV (J. Gen. Chem. Russ., 1935, 5, 1359—1372; cf. A., 1935, 932, 1320).—The fractions (I) of agar of smaller mol. wt. are extractable with cold  $\text{H}_2\text{O}$ , and are shown to exert a stabilising action on sols of the fractions (II) of higher mol. wt., and to augment imbibition of  $\text{H}_2\text{O}$  by gels of the latter, to an extent commensurate with difference in osmotic pressure between intra- and extra-micellar (I). \*The  $\eta$  of sols of (II) is  $<$  that of the original product, owing to their smaller structural  $\eta$ , and to the smaller vol. of the dispersed phase. R. T.

**Stability of colloids. II. Negative silver iodide colloid.** A. BASIŃSKI (Rocz. Chem., 1935, 15, 430—440; cf. A., 1935, 297).—The coagulating action of cations on dialysed negatively charged  $\text{AgI}$  sol diminishes in the series  $\text{Li} > \text{Na} > \text{K} > \text{NH}_4 > \text{H} > \text{Ag}$ ;  $\text{Cd} > \text{Mg} > \text{Mn}^{II} > \text{Co} > \text{Zn} > \text{Ni} > \text{Ca} > \text{Sr} > \text{Cu} > \text{Ba} > \text{Pb}^{II}$ ;  $\text{Fe}^{III} > \text{La}^{III} > \text{Ce}^{III} > \text{Al}$ ;  $\text{Zr}^{IV} > \text{Th}^{IV}$ .

The action of univalent cations is antagonistic to that of bi- and ter-valent ions; when uni- and quadri-valent ions are present together antagonism is observed only with  $\text{LiCl}$ . An interpretation of the above phenomena, based chiefly on considerations of exchange adsorption, is advanced. R. T.

**Zonal effect in the electrolytic coagulation of manganese dioxide.** S. S. JOSHI and S. J. RAO (Current Sci., 1936, 4, 481—482).—In  $> 80$  cases  $n$  during slow coagulation varies discontinuously with the time, in disagreement with Smoluchowski's theory. R. S. B.

**Coagulation of solvated sols by organic substances and salts. VI. Temperature-stable albumin sols which coagulate on cooling.** B. JIRGENSONS (Kolloid-Z., 1936, 74, 205—208; cf. A., 1933, 461).—Sols of ovalbumin containing 45—55 vol.-% of  $\text{Pr}^{\text{OH}}$  or  $\text{Pr}^{\text{OH}}$  and 0.05—0.5M with respect to  $\text{NaBr}$ ,  $\text{KCl}$ ,  $\text{CaCl}_2$ , or  $\text{Ca}(\text{NO}_3)_2$ , are stable at room temp. or at  $40^\circ$ , and coagulate at  $-8^\circ$  to  $-10^\circ$ . The coagulum can be re-dispersed at  $65^\circ$ . An explanation is put forward. F. L. U.

**Ionic structure, solubility, and coagulation of proteins.** F. HAUROWITZ (Kolloid-Z., 1936, 74, 208—218; cf. A., 1935, 822).—Solubilities at different  $p_H$  have been determined for products formed by coupling albumin or globulin with diazotised  $m$ - $\text{NH}_2 \cdot \text{C}_6\text{H}_4 \cdot \text{SO}_3\text{H}$ ,  $p$ - $\text{NH}_2 \cdot \text{C}_6\text{H}_4 \cdot \text{AsO}(\text{OH})_2$ , or  $o$ - $\text{NH}_2 \cdot \text{C}_6\text{H}_4 \cdot \text{CO}_2\text{H}$ . Data are recorded for the pptn. of various proteins by elupein (which ppts. only the protein anion), and by ovalbumin into which  $\text{SO}_3\text{H}$  have been introduced as above until the isoelectric point is at  $p_H < 1$ , whereby only the protein cations are pptd. The results are discussed theoretically. F. L. U.

**Mitogenetic radiations and Liesegang rings.** A. E. ROFFO (Rev. soc. argentina biol., 1934, 10, 297—305).—Small amounts of rat tissue supported close above a gelatin film cause an outward distortion and some thickening of  $\text{AgNO}_3 \cdot \text{K}_2\text{Cr}_2\text{O}_7$  rings formed on the film. The action of sarcoma tissue is  $>$  that of normal tissue. CH. ABS. (p)

**Thixotropy and rheopexy of  $\text{V}_2\text{O}_5$  sols.** F. JULIUSBURGER and A. PIRQUET (Trans. Faraday Soc., 1936, 32, 445—452).—The relation between thixotropy and rheopexy (cf. A., 1935, 933) has been investigated in more detail for  $\text{V}_2\text{O}_5$  sols. Freshly prepared  $\text{V}_2\text{O}_5$  sols with amiconic particles are only thixotropic, but as soon as large needle-shaped particles are formed the sols become rheoplectic. Rheoplectic sols can be made with Li salts or with acids, but not with K or  $\text{NH}_4$  salts, although the latter can produce thixotropic  $\text{V}_2\text{O}_5$  sols. Li salts and acids are weak coagulants for  $\text{V}_2\text{O}_5$  sols. Rheopexy appears to be an intermediate state between a stable sol and one coagulated by stirring, just as thixotropy is in many cases an intermediate state between a stable sol and one coagulated by electrolytes. O. J. W.

**Mechanism and kinetics of thixotropic solidification.** W. HELLER (Compt. rend., 1936, 202, 61—64).—Data are recorded for the rate of gel formation of  $\text{Fe}(\text{OH})_3$  sols containing  $\text{NaCl}$ , after centrifuging. This is determined by the rate at

which nuclei form, by the rate of growth of these nuclei, and by the rate of their association.

H. J. E.

**Structure and properties of thixotropic gels.** B. S. KANDELAKY (Kolloid-Z., 1936, 74, 200—205).—Sols of  $\text{Fe}_2\text{O}_3$  made by hydrolysis of  $\text{Fe}(\text{OEt})_3$  can set to thixotropic gels when containing as little as 6.3 g. of  $\text{Fe}_2\text{O}_3$  per litre. With increasing val. of  $\text{EtOH}/\text{H}_2\text{O}$  in the sol the particle size increases and the stability decreases. The time needed for the first setting is  $>$  for subsequent settings, owing to the incomplete breaking up of the aggregates on shaking. No thixotropic gels can be obtained from sols made from recryst.  $\text{Fe}(\text{OEt})_3$  and containing no excess electrolyte, whence it is inferred that at least some stabilising charge is necessary. Ultramicroscopic observations establish the existence of a network of aggregates in which the liquid is enmeshed. That the intracellular liquid does not "set" is shown by the appearance in it of small particles in Brownian movement when the system as a whole is gelatinised.

F. L. U.

**Sol-gel transformations. II. Dilatometric investigations on iron hydroxide, gelatin, methylcellulose, silicic acid, and viscose.** E. HEYMANN (Trans. Faraday Soc., 1936, 32, 462—473; cf. A., 1935, 822).—Changes associated with sol-gel transformations have been studied with a sensitive Hg dilatometer. With methylcellulose the vol. increases, with gelatin it decreases, whilst no vol. change occurs during the thixotropic sol-gel transformation of  $\text{Fe}(\text{OH})_3$  sol. It is suggested that a vol. increase corresponds with a decrease in hydration, since the bound  $\text{H}_2\text{O}$  has a smaller sp. vol. than that of the free  $\text{H}_2\text{O}$ . In the formation of silicic acid gels from Na silicate and HCl, the vol. increase is about 10—20 times as large. There is, moreover, a further increase in vol. which continues for many months. Chemical dehydration due to polymerisation may be the cause of these large vol. changes. The maturing of viscose solutions is also discussed.

O. J. W.

**Structures of precipitates. I. Influence of hydrogen, lithium, sodium, and potassium ions on peptisability of secondary particles of barium sulphate precipitates.** B. TEŽAK (Z. physikal. Chem., 1936, 175, 284—293).—The peptisability with  $\text{H}_2\text{O}$  of a  $\text{BaSO}_4$  ppt. varies with the cation of the pptg. sulphate according to the lyotropic series  $\text{Li}^+ > \text{Na}^+ \approx \text{H}^+ > \text{K}^+$ . It is inferred that the reversibility of the aggregation of the primary particles is determined by the hydration of the adsorbed foreign ions. There may be differences in magnitude and sign of charge between different fractions of a peptised system. For a  $\text{BaSO}_4$  dispersion the dispersity quotient falls linearly with increasing particle size.

R. C.

**Atomically divided silver.** A. TOPOREK (Compt. rend. Acad. Sci. U.R.S.S., 1935, 4, 27—30).—The absorption spectra of Ag dispersed in KCl, KBr, and KI are recorded. The colloidal nature of the colour centres is discussed.

H. J. E.

**Swelling solution temperature of cassava starch.** A. J. OPHOF (Chem. Weekblad, 1936, 33,

91—93).—The percentage ( $P$ ) of cassava starch granules remaining undissolved in  $\text{H}_2\text{O}$  at any temp. has been determined microscopically with Congo-red as stain.  $P$  reaches an equilibrium val. in  $< 30$  min. which increases with temp., following an S-curve reaching 50% at  $61.07^\circ$  (by definition, the swelling solution temp.) and 95% at about  $65^\circ$ . The results are similar to those of Arzichovski (Bull. Acad. Sci. U.R.S.S., 1918, 12, 349) for potato starch. Samec's method (A., 1912, ii, 144) gives vals. of  $55.6$ — $59^\circ$  for cassava starch and  $59.1$ — $60.3^\circ$  for potato starch, but these depend on the concn.

D. R. D.

**Vapour pressure-water content relations for certain typical soil colloids.** L. T. ALEXANDER and M. M. HARRING (J. Physical Chem., 1936, 40, 195—205).—The colloids have been extracted from four different types of soil representing a wide range of progressive weathering, and the variations of v.p. with different  $\text{H}_2\text{O}$  content of the colloids have been determined. The curves are characteristically different for the different types of soil. The variation of free energy with  $\text{H}_2\text{O}$  content has been calc. and the free energy of wetting determined approx. The relation of v.p. to colloid composition is discussed. A theory of the nature of hygroscopic  $\text{H}_2\text{O}$  in soil colloids is given.

M. S. B.

**Equilibrium constants of the exchange reactions  $\text{HCl} + \text{HD} = \text{DCl} + \text{H}_2$  and  $\text{HBr} + \text{HD} = \text{DBr} + \text{H}_2$ .** K. WIRTZ (Z. physikal. Chem., 1936, B, 31, 309—318).—Assuming that the rotation of the mols. concerned is fully excited and the vibration unexcited the equilibrium consts. are calc. to be  $([\text{HD}][\text{HCl}])/([\text{H}_2][\text{DCl}]) = 2.362e^{-186.77/T}$  and  $([\text{HD}][\text{HBr}])/([\text{H}_2][\text{DBr}]) = 2.414e^{-128.11/T}$ . These agree with the observed equilibrium consts., using Pt to catalyse the exchange. In each case the partition ratio of  $D$  approximates to 1 and is practically independent of the temp. From these data and the equilibrium const. of  $\text{H}_2 + \text{D}_2 = 2\text{HD}$  (cf. A., 1934, 30) the equilibrium consts. of all the other exchange reactions possible in the systems H-D-halogen may be calc.

R. C.

**Equilibrium of exchange reactions with deuterium.** K. WIRTZ (Physikal. Z., 1936, 37, 165).—The exchange of D and H in HCl, HBr, and  $\text{NH}_3$  has been studied by determining the equilibrium isotopic ratio for mixtures of  $\text{D}_2$  and the above gases in presence of a Pt catalyst by the thermal conductivity method. The results are in good agreement with those calc. from spectroscopic data (cf. A., 1935, 1460).

A. J. M.

**Equilibria of the reactions between acetylene and heavy water at  $25^\circ$ .** L. H. REYERSON and B. GILLESPIE (J. Amer. Chem. Soc., 1936, 58, 282—284).—Equilibrium consts. for the reactions involving  $\text{H}_2\text{O}$ ,  $\text{HDO}$ ,  $\text{D}_2\text{O}$ ,  $\text{C}_2\text{H}_2$ ,  $\text{C}_2\text{HD}$ , and  $\text{C}_2\text{D}_2$  have been determined.

E. S. H.

**Concentration maximum of endothermic compounds at high temperatures. Application to ozone and nitric oxide.** E. BRINER, B. SUSZ, and E. ROD (Arch. Sci. phys. nat., 1935, [v], 17, Suppl., 198—200).—Previous results (A., 1931, 910) have been recalc. using recent experimental data.

The max. concn. of  $O_3$  in  $O_2$  at 1 atm. is  $2.2 \times 10^{-5}\%$  at  $3500^\circ$  abs. and that of  $NO$  in air at 1 atm. is  $4.7-7.5\%$  at  $3500^\circ$  abs. R. S.

**Relative values of the four butane-butene-hydrogen equilibrium constants.** L. S. KASSEL (J. Chem. Physics, 1936, 4, 144).—The method of Eidinoff *et al.* (A., 1935, 1064) has been developed and applied to calculate the vals. of the sum of the translational and the rotational entropies of the following compounds at  $25^\circ$ : *n*-butane 75.366, isobutane 71.249,  $\Delta^a$ -butene 72.98, *cis*- $\Delta^b$ -butene 68.225, *trans*- $\Delta^b$ -butene 67.800, isobutene 68.215. The possibility of determining vibrational entropy is discussed.

M. S. B.

**Activity of water in solutions of barium chloride.** R. F. NEWTON and E. A. TIPPETTS (J. Amer. Chem. Soc., 1936, 58, 280–282).—V.p. of  $BaCl_2$  solutions at  $25^\circ$  have been measured and the activity of  $H_2O$  has been calc.

E. S. H.

**Vapour pressures and activity coefficients of aqueous solutions of calcium and aluminium nitrate at  $25^\circ$ .** J. N. PEARCE (J. Amer. Chem. Soc., 1936, 58, 376–377).—Corr. data are given (cf. A., 1935, 302).

E. S. H.

**Calculation of activity coefficients and molal volumes.** O. REDLICH, P. ROSENFELD, and W. STRICKS (J. Amer. Chem. Soc., 1936, 58, 375–376).—A criticism (cf. Pearce and Blackman, A., 1935, 302).

E. S. H.

**Equilibrium and free energy relationships in the system acetone-diacetone alcohol.** G. L. DAVIS and G. H. BURROWS (J. Amer. Chem. Soc., 1936, 58, 311–312).—The partial pressures of  $COMe_2$  at  $25^\circ$  show that the mixture forms a perfect solution. The v.p. of diacetone alcohol (I) has been determined at  $25^\circ$ ,  $35^\circ$ , and  $45^\circ$ . The free energy change and heat of reaction of transformation of  $COMe_2$  into (I) have been calc.

E. S. H.

**Condition of iodic acid and iodates in aqueous solution.** N. R. DHAR and R. N. MITTRA (J. Indian Chem. Soc., 1935, 12, 771–773).—The coagulating power of aq.  $HIO_3$  and  $KIO_3$  on sols of  $Be(OH)_2$ ,  $Cr(OH)_3$ , and  $Th(OH)_4$ , and the variation of mol. conductivity of aq.  $KIO_3$  on dilution, indicate partial polymerisation. Evidence from Raman spectra is inconclusive.

E. S. H.

**Mannitoldimolybdic acid.**—See this vol., 453.

**Strength of isomeric bases of the type  $[Pt(NH_3)_2(OH)_2]$ .** A. A. GRÜNBERG and D. I. RJABTSCHIKOV (Compt. rend. Acad. Sci. U.R.S.S., 1935, 4, 259–262).—Titration of the *cis*-compound with 0.1N-HCl at room temp. gives a colour change with Mc-red when 80% of the theoretical amount of acid has been added owing to the formation of the weak acid  $[Pt(NH_3)_2(H_2O)_2]^{++}$ . The change  $[Pt(NH_3)_2(H_2O)_2]Cl_2 \rightarrow [Pt(NH_3)_2Cl_2] + 2H_2O$  occurs on warming and the theoretical end-point may be attained. The *trans*-compound gives an end-point at room temp. corresponding with 50% of the theoretical amount of acid and this is attributed to the formation of  $[Pt(NH_3)_2(H_2O)(OH)]Cl$ . The final titration val. is obtained on warming.

R. S.

**Colorimetric researches on naphthazarin and dibromonaphthazarin.** L. BRÜLL and P. GIROTTI (Annali Chim. Appl., 1936, 26, 19–24).—The dissociation consts. of naphthazarin determined colorimetrically with  $KH_2PO_4$ -NaOH and  $H_3BO_3$ -KCl-NaOH buffers, and with NaOH, are  $K_1 = 6.3 \times 10^{-9}$ ,  $K_2 = 2.5 \times 10^{-11}$ ; those of *dibromonaphthazarin*, m.p.  $163^\circ$  ( $Ac_2$  derivative, m.p.  $212-213^\circ$ ), are  $K_1 = 3.2 \times 10^{-7}$ ,  $K_2 = 2.5 \times 10^{-10}$ . The possibility of using naphthazarin as indicator in the colorimetric determination of  $p_H$  from 7 to 12 is considered; the quantities of naphthazarin in 0.1N-HCl and 0.1N-NaOH required to match the colour of a given solution at each  $p_H$  are tabulated.

E. W. W.

**Application of the phase rule to systems containing distant phases.** F. J. TROMP (J. Chem. Met. Soc. S. Africa, 1935, 36, 143–145; cf. A., 1934, 1307).—When the phase rule is applied to systems such as  $H_2O$  vapour in contact with separate solutions of different salts, the no. of components must be taken as  $>$  the no. of constituents in the system and so the ordinary statement of the phase rule is inapplicable. The author's treatment can be extended to such systems without introduction of special assumptions.

J. W. S.

**Crystalline varieties of the hydrated nitrites of barium and strontium: the hydrate  $Sr(NO_2)_2 \cdot 4H_2O$ .** J. BUREAU (Compt. rend., 1936, 202, 307–309).— $Ba(NO_2)_2 \cdot H_2O$  exists in hexagonal and rhombic forms. The equilibrium diagram for  $Ba(NO_2)_2 \cdot H_2O$  is described.  $Sr(NO_2)_2$  forms the hydrate  $Sr(NO_2)_2 \cdot 4H_2O$  (cubic), which undergoes a peritectic transformation into the hexagonal monohydrate at  $15^\circ$ .

H. J. E.

**Decomposition pressures of the ammoniates of sodium and ammonium chlorides.** S. ABE, K. WATANABE, S. SIGETOMI, and R. HAVA (J. Soc. Chem. Ind. Japan, 1936, 39, 18–20B).—The compounds  $NaCl \cdot 5NH_3$  and  $NH_4Cl \cdot 3NH_3$  have been prepared. Apparatus and methods for studying the decomp. are described. Results are given for the change  $NaCl \cdot 5NH_3 \rightleftharpoons NaCl + 5NH_3$  over the temp. range  $-10^\circ$  to  $-30^\circ$  and for  $NH_4Cl \cdot 3NH_3 \rightleftharpoons NH_4Cl + 3NH_3$  over the range  $5^\circ$  to  $-53^\circ$ . Heats of formation are computed.

T. W. P.

**Volatilisation of lead oxide from lead oxide-silica mixtures.** E. PRESTON and W. E. S. TURNER (J. Soc. Glass Tech., 1935, 19, 296–311T).—Measurements at  $900-1200^\circ$  for mixtures containing 53.96–99.8% of  $PbO$  show that the rate of volatilisation exhibits discontinuities which are attributed to the presence of  $PbO \cdot SiO_2$ ,  $2PbO \cdot SiO_2$ , and  $4PbO \cdot SiO_2$ . The heats of decomp. and evaporation of these compounds are  $-56,000$ ,  $-49,000$ , and  $-30,000$  g.-cal. per mol., respectively. The v.p. of pure  $PbO$  at  $1100^\circ$  is 70 mm. of Hg. The general results confirm those previously obtained for the  $Na_2O-SiO_2$  and  $K_2O-SiO_2$  systems.

J. A. S.

**Fusion curve of the system *o*- and *p*-cresols.** S. TSURUTA (J. Chem. Soc. Japan, 1935, 56, 429–432).—Dawson and Mountford's results are confirmed (cf. J.C.S., 1918, 113, 923).

CH. ABS. (c)

The system: *p*-nitrotoluene-2-chloro-4-nitrotoluene-2 : 6-dichloro-4-nitrotoluene. O. J. MAGIDSON and V. A. SCHEVELEV (J. Appl. Chem. Russ., 1935, 8, 1431—1434).—The m.-p. diagrams afford no evidence of compound formation. R. T.

Equilibria in saturated solutions of salts occurring in sea-water. I. Ternary systems  $\text{MgCl}_2\text{-KCl-H}_2\text{O}$ ,  $\text{MgCl}_2\text{-CaCl}_2\text{-H}_2\text{O}$ ,  $\text{CaCl}_2\text{-KCl-H}_2\text{O}$ , and  $\text{CaCl}_2\text{-NaCl-H}_2\text{O}$  at  $0^\circ$ . I. IGELSRUD [with T. G. THOMPSON] (J. Amer. Chem. Soc., 1936, 58, 318—322).—Equilibria have been determined at  $0^\circ$ . The KCl content of solutions saturated with  $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$  is very small. There is no evidence for double salt formation in the system  $\text{CaCl}_2\text{-KCl-H}_2\text{O}$ . E. S. H.

Thermodynamic study of systems of the type  $\text{PbCl}_2\text{-RCl-H}_2\text{O}$  at  $25^\circ$ . V. E. HUNTER and A. J. ALLMAND (Trans. Faraday Soc., 1936, 32, 502—511; cf. A., 1933, 906).—The v.p. at  $25^\circ$  of solutions containing KCl and  $\text{PbCl}_2$  in equilibrium with various solid phases and also of certain unsaturated solutions have been determined. The results do not agree with vals. calc. from electrometric data, which are probably not sufficiently accurate. Over a narrow concn. region abnormally high v.p., approaching that of pure  $\text{H}_2\text{O}$ , are obtained. In the region of normal v.p. there is evidence of the presence of complexes in the solution. O. J. W.

Ternary system  $\text{NaCl-NaI-H}_2\text{O}$ . J. E. RICOI and N. S. YANICK (J. Amer. Chem. Soc., 1936, 58, 313—315).—Solubility data at  $10^\circ$ ,  $25^\circ$ ,  $50^\circ$ ,  $75^\circ$ , and  $100^\circ$  are recorded. Within this range neither double salts nor solid solutions are formed. E. S. H.

System mercuric iodide, caesium iodide, water. (JLLE.) M. PERNOT (Compt. rend., 1936, 202, 576—578).—The existence of  $3\text{HgI}_2 \cdot 2\text{CsI}$ ,  $\text{HgI}_2 \cdot 2\text{CsI}$ , and  $\text{HgI}_2 \cdot 3\text{CsI}$  has been confirmed. T. G. P.

System  $\text{CaO-SO}_2\text{-H}_2\text{O}$ . III. Precipitation temperatures. P. E. GISHLER and O. MAASS (Canad. J. Res., 1935, 13, B, 370—379).—A technique is described for measuring pptn. temp., and the results over a concn. range are tabulated. Colloidal matter causes supersaturation.  $[\text{H}^+]$  and  $[\text{HSO}_3^-]$  at the pptn. temp. have been calc.  $[\text{H}^+]$  probably plays an important part in pptn., and the increased pptn. with rising temp. above the pptn. temp. is explained.  $\text{HSO}_3^-$  concns. for a range of CaO and  $\text{SO}_2$  concns. from  $50^\circ$  to  $90^\circ$  are given. The system acts as a buffer in so far as  $\text{HSO}_3^-$  ions are concerned. E. E. A.

Fusion surface of the ternary system of organic compounds. I. T. ASAHINA and K. YOKOYAMA (J. Chem. Soc. Japan, 1935, 56, 415—428).—The system picric acid (I)- $\beta\text{-C}_{10}\text{H}_7\text{-OH}$  (II)-chalkone (III) has eutectic points at  $70^\circ$  [(I) 5.5, (II) 43, (III) 51.5%],  $84^\circ$  [(I) 25.5, (II) 16, (III) 58.5], and  $103^\circ$  [(I) 85, (II) 7.5, (III) 7.5%]. CH. ABS. (e)

Transformation of an incongruently fusing binary compound into a ternary eutectic. X. Carbamide-veronal-resorcinol. F. ADAMANIS (Rocz. Chem., 1935, 15, 546—553).—Thermal analysis indicates the existence of three 1 : 1 compounds, three ternary eutectics, and a peritectic. The system is

peculiar in that one of the compounds passes at the transition point into a ternary eutectic. R. T.

Specific heats of aqueous solutions of potassium chloride. C. J. B. CLEWS (Proc. Physical Soc., 1936, 48, 95—99).—Data for  $15\text{--}45^\circ$  and 0.1—2.5*N* are tabulated. The temp. coeff. decreases with concn. N. M. B.

Heat content of sodium chloride in extremely dilute aqueous solutions. T. F. YOUNG and W. L. GROENIER (J. Amer. Chem. Soc., 1936, 58, 187—191).—Theoretical. The chord-area method has been applied to published data for heats of dilution. E. S. H.

Sodium hydroxide solutions. Heat of dilution at  $20^\circ$ . J. W. BERTETTI and W. L. MCCABE (Ind. Eng. Chem., 1936, 28, 247—248).—The heat of dilution has been determined at  $20^\circ$  for the concn. ranges 13.59—26.14 and 17.16—48.14% NaOH. Results are slightly lower than those of Fricke (A., 1929, 1386) but agree with those of Tucker (A., 1915, ii, 674) after correcting for sp. heat. R. S. B.

Heat of hydrogenation of diisobutylene. B. L. CRAWFORD, jun., and G. S. PARKS (J. Amer. Chem. Soc., 1936, 58, 373).—Direct calorimetric measurements give  $\Delta H_{298}^\circ = -28,580 \pm 800$  g.-cal. for the reaction  $\text{C}_8\text{H}_{16}(l) + \text{H}_2(g) = \text{C}_8\text{H}_{18}(l)$ . E. S. H.

Electrolytic conductivity of calcium hydrogen sulphite solutions at  $20^\circ$ . (System  $\text{CaO-SO}_2\text{-H}_2\text{O}$ .) G. K. BERGMAN (Finnish Paper Timber J., 1935, Spec. Issue, 290—293).—Vals. for the conductivity of  $\text{CaO-SO}_2$  solutions are given. The  $[\text{CaO}]$  can be deduced from the conductivity and  $[\text{SO}_2]$ . CH. ABS. (e)

Properties of electrolytic solutions. XVII. Conductance of salts in benzene and dioxan. W. F. LUDER and P. B. KRAUS [with C. A. KRAUS and R. M. FUOSS] (J. Amer. Chem. Soc., 1936, 58, 255—258; cf. A., 1935, 705).—Data are given for tetraisoamylammonium iodide in  $\text{C}_6\text{H}_6$  at  $60^\circ$ , for  $\text{AgClO}_4$  in  $\text{C}_6\text{H}_6$  at  $25^\circ$ , and for  $\text{NBu}_4\text{-ClO}_4$  and  $\text{NBu}_4\text{-OAc}$  in  $\text{C}_6\text{H}_6$  and dioxan at  $25^\circ$ . The equiv. conductances show min. at low concns., below which they rise in accordance with the mass action law. A marked sp. effect of structure on conductance in solvents of very low dielectric const. is noted. E. S. H.

High- and low-frequency conductivities of solutions of electrolytes in glycerol and glycerol-water mixtures. J. HIEGEMANN (Ann. Physik, 1936, [v], 25, 337—358).—Published conductivity data for glycerol solutions agree with the square root law, but the slope is steeper than that required by the Debye-Onsager theory. Solutions of KCl and  $\text{MgSO}_4$  in glycerol and glycerol- $\text{H}_2\text{O}$  have been measured by the abs. method of Malsch, using a miniature thermostat (described). The results obtained are in close agreement with the requirements of the Debye theory for the solvents used. The ionic effects for both solutes are much  $>$  any previously reported. W. R. A.

New method of determining hydration of  $\text{SO}_4^{2-}$  from the electrolytic transport of water. J. BABOROVSKÝ (Chem. Listy, 1936, 30, 5—6).—The hydration of  $\text{SO}_4^{2-}$  cannot be determined directly, owing to the solubility of the depolarisers which

have to be used; an indirect method is proposed, based on measurement of the electrolytic transport of  $H_2O$  in a cell consisting of Ag-AgCl electrodes in  $N-KCl$ , separated by parchment-paper diaphragms from a central chamber containing an equiv. concn. of  $K_2SO_4$ . R. T.

**Electrochemical study of lithium, rubidium, and silver bromides in a solution of aluminium bromide in ethyl bromide.** V. A. PLOTNIKOV and E. J. GORENBEIN (J. Gen. Chem. Russ., 1935, 5, 1434—1440).—The val. of the max. sp. conductivity of the system  $MBr-AlBr_3-EtBr$  falls in the series  $Ag > Li > Cu > K > Rb$ . Except with  $AgBr$ ,  $Al$  is deposited at the cathode in all the systems, the decomp. potentials being:  $LiBr$  2,  $RbBr$  1.66,  $AgBr$  1.3 volts. R. T.

**Electrochemical study of solutions of acetamide in bromine.** V. A. PLOTNIKOV and S. I. JAKUBSON (J. Gen. Chem. Russ., 1935, 5, 1337—1341).—The conductivity max. corresponds with  $NH_2Ac_6Br$ ;  $Br$  is liberated at the anode, and  $NH_2Ac$  at the cathode. R. T.

**Metal-metal potential in the e.m.f. of electrochemical cells.** E. LANGE and K. NAGEL (Z. Elektrochem., 1936, 42, 50—65).—Theoretical. The source of the e.m.f. is discussed. E. S. H.

**Electrode potential of iron in relation to hydrogen-ion concentration.** J. W. SHIPLEY and J. H. SHIPLEY (Canad. J. Res., 1936, 14, B, 31—40).—The final electrode potentials observed when  $Fe$  has been immersed for several days in phosphate, borate, and citrate buffers show sharp falls of 0.74, 0.75, and 0.77 volts which occur at  $p_H$  3.1—4.0, 4.3—4.6, and 10.1—10.9, respectively, for the three series of buffer solutions. Bubbling  $H_2$  or  $O_2$  through the solutions has little effect, but the presence of  $Cl^-$  causes the breaks to be less marked and displaces them to higher vals. of  $p_H$ . Corrosion takes place when the  $p_H$  vals. are below those at which the breaks occur. It is suggested that the electrode potential is determined by the presence or absence of a non-conducting film on the  $Fe$ . L. A. O'N.

**Diffusion potentials and mobilities of ionised gelatin. II. Neutral and alkaline solutions.** E. B. R. PRIDEAUX (Trans. Faraday Soc., 1936, 32, 576—582; cf. A., 1935, 300).—Diffusion potentials of  $K$  gelatinate have been determined in dil. solutions at  $p_H$  6—10. The calc. mobility of the gelatin anion, nearly 40, agrees fairly with that found (A., 1932, 470) in much more conc. solutions. F. L. U.

**Decomposition and equilibrium reaction potentials of fused potassium chloride.** R. C. KIRK and W. E. BRADT (Trans. Electrochem. Soc., 1936, 69, Preprint, 75—88).—The decomp. voltage of fused  $KCl$  at  $800^\circ$  is 2.8 volts. By substituting a  $Cl_2$  anode and using a supplementary cathode the equilibrium potential of the cell  $K|KCl|Cl_2$  has been determined. The p.d. between anode and cathode increases almost linearly with increasing anodic c.d., and reaches a max. val. of 3.37 volts when the anodic c.d. is 1.0 amp. per sq. cm., which is in close agreement with the calc. val. of 3.32 volts for a cell with  $Cl_2$  at atm. pressure. With graphite electrodes depolarisation may reach 0.47 volt, and

is attributed either to anodic formation of  $CCl_4$  or to liberation of  $K$  carbide at the cathode.

J. W. C.

**Oxidation potential of the system potassium molybdocyane-potassium molybdicyanide, and the effect of neutral salts on the potential.** I. M. KOLTHOFF and W. J. TOMSICEK (J. Physical Chem., 1936, 40, 247—255; cf. A., 1935, 1462).—The normal potential of the system, extrapolated to zero ionic strength, is 0.7260 volt at  $25^\circ$ . Neutral salts increase the oxidation-reduction potential to a large extent. For univalent cations the effect decreases in the order  $K^+ = NH_4^+ > Na^+ > Li^+ > H^+$ . Bivalent cations at the same ionic strength have a much greater effect decreasing in the order  $Ba^{++} > Sr^{++} > Ca^{++}$ . The vals. of  $\log f_3/f_4$ , calc. from experimental data, are respectively  $<$  and  $>$  those calc. from the Debye-Hückel expression. M. S. B.

**Polarographic studies with the dropping mercury electrode. III. Cause of maxima on current-voltage curves.** D. ILKOVIČ (Coll. Czech. Chem. Comm., 1936, 8, 13—34).—Certain assumptions lead to the view that the intensity of the electric field is large close up to the dropping  $Hg$  electrode and falls rapidly towards the interior of the solution. This field attracts charged particles and dipoles much more strongly than the electrokinetic potential, and during the action of the "charging (non-faradic) current," the electrically adsorbable particles of the depolariser are drawn into and stored in this non-homogeneous field. If the applied e.m.f. is so large that the rate of exhaustion of the depolariser is  $>$  its rate of adsorption, polarisation starts at the electrode surface, destroying the non-homogeneous field in solution and leaving a very steep fall of potential very close to the interface. From this theory, conditions are derived mathematically, and confirmed by experiments with 0.002—0.01N- $KCl$  containing air, under which a large "adsorption current" and a small "diffusion current" with transition of the former into the latter appear on current-time curves during the charging in the formation of a single  $Hg$  drop at const. applied e.m.f. The current-voltage curve derived from these curves is confirmed experimentally. The theory explains the origin of the max. arising in current-voltage curves under various conditions with the dropping  $Hg$  cathode and predicts conditions under which similar max. may be realised with large stable  $Hg$  electrodes. J. G. A. G.

**Simultaneous discharge of cadmium and hydrogen ions from solutions of simple salts of cadmium.** O. ESSIN, T. BEKLEMISHEVA, and A. MATANTZEV (J. Gen. Chem. Russ., 1935, 5, 1383—1386).—An equation connecting the amount of  $Cd$  deposited per unit of current with the concn. of acid present (A., 1935, 310) has been verified for solutions of 0.25—1.0N- $CdSO_4$  in 0.1—10N- $H_2SO_4$ , for currents of 0.005—0.1 amp. per sq. cm., at  $25^\circ$ . R. T.

**Overvoltage and electrolytic separation of hydrogen isotopes.** J. HORIUTI and G. OKAMOTO (Sci. Papers Inst. Phys. Chem. Res. Tokyo, 1936, 28, 231—242; cf. A., 1934, 153, 258).—Overvoltage

and current, and the velocity of exchange between H and D at an anodically polarised Ni-H electrode in 0.001*N*-H<sub>2</sub>SO<sub>4</sub>, and in contact with H<sub>2</sub> containing 3% of D<sub>2</sub>, have been determined. Parallel measurements of the electrolytic separation factor have been made. A theory of the electrode processes is put forward, and an explanation of Tafel's empirical equation is given. F. L. U.

**Polarisation discharges in multiple electrode systems.** H. HUNT, J. F. CHITTUM, and H. M. GRUBB (J. Physical Chem., 1936, 40, 239—245).—The conditions governing the production of currents between polarised exploring electrodes immersed in an electrolytic cell have been investigated. The phenomena observed originate in the polarisation at the ends of the electrodes and in the differential polarisation of each of the current electrodes at different points on the surface. The significance of these phenomena in electrolytic investigations is indicated. M. S. B.

**Anode process in electrolysis of aqueous alkali chloride solutions with impregnated and non-impregnated graphite electrodes. I. II. Liberation of chlorine and oxygen at the anode. III. Influence of impregnation of the graphite electrode on the anode process. V. S. JOFFE. IV. Electro-capillary phenomena. V. S. JOFFE and M. M. STROGANOV (Z. Elektrochem., 1936, 42, 71—76, 76—79, 79—82, 82—85).—I. The distribution of current between the outer surface of the porous electrode and the inner pore surface depends on the resistivity of the electrode and on the nature of the p.d.-c.d. relation. Discharge of ions occurs throughout the whole cross-section of the electrode, but is conc. mainly in the outer layer. When the pores are filled by impregnation with linseed oil, electrolysis occurs only at the outer surface.**

**II. The ratio O<sub>2</sub>:Cl<sub>2</sub> is greater in the anode gas liberated in the pores than in that liberated at the outer surface of the electrode, and passes through a min. at medium c.d.**

**III. The polarisation of the graphite anode in aq. NaCl has been studied. Under certain conditions of impregnation with oil, oxidation of C occurs and the anode suffers disruption.**

**IV. During anodic polarisation the electrolyte displaces air from the non-impregnated and oil from the impregnated graphite electrode. E. S. H.**

**Electrometallurgy of aluminium. P. DROSSBACH (Z. Elektrochem., 1936, 42, 65—70).—The equilibrium Na<sub>3</sub>AlF<sub>6</sub>-Li<sub>3</sub>AlF<sub>6</sub>-Al<sub>2</sub>O<sub>3</sub> has been investigated at 750—1000°. Current efficiency and polarisation potential in the electrolysis of such mixtures have been determined. E. S. H.**

**Passivity of iron and steel in nitric acid solution. VIII. Y. YAMAMOTO (Bull. Inst. Phys. Chem. Res. Japan, 1936, 15, 15—21; cf. A., 1934, 1463).—The ability of HNO<sub>3</sub> to render Fe passive is increased and the concn. at which the effect appears is lowered by the addition of nitrates, with the exception of Cu(NO<sub>3</sub>)<sub>2</sub>. HNO<sub>2</sub> and higher nitrates of the metals are formed. AgNO<sub>3</sub> is especially effective and causes passivity in relatively dil. solutions of HNO<sub>3</sub>. R. S. B.**

**Valency-linking shifting in cyclanes. J. BÖESEKEN (Proc. K. Akad. Wetensch. Amsterdam, 1936, 39, 28—30; cf. A., 1932, 269).—The influence of 1-hydroxycyclo-heptane-, -hexane-, -pentane-, -butane-, and -propane-1-carboxylic acids on the conductivity of 0.5*M*-H<sub>3</sub>BO<sub>3</sub> has been determined and compared with corresponding data for disubstituted glycollic acids. Saturated ring compounds with > 5 members increase the conductivity to the same extent as the open-chain compounds, but in the case of 3- and 4-C rings the effect is much less. It is inferred that the valency linkings in rings containing < 5 C are shifted by the ring-closure. R. S.**

**Explosive reactions and analytical geometry. W. P. JORISSEN (Chem. Weekblad, 1936, 33, 83—90).—The factors governing the form of the curves representing the explosion limits of ternary gaseous mixtures are discussed. D. R. D.**

**Pressure dependence of unimolecular reactions. E. A. STEWARDSON (Phil. Mag., 1936, [vii], 21, 233—248).—Theoretical. The chance that an activated mol. in a quasi-unimol. reaction will dissociate, and the ratio (*r*) of the velocity coeffs. (*k*) of the unimol. and bimol. reactions are calc. In agreement with experiment it is inferred that increases in temp. and pressure produce changes in *r* in opposite directions, and that the addition of a light gas will maintain the unimol. rate. Good agreement is obtained with the dissociation of N<sub>2</sub>O, except at low pressures, giving an average life of an activated complex (*τ*) of 10<sup>-11</sup> sec. With other reactions agreement is poor, but *τ* may be approx. estimated to be 10<sup>-6</sup>—10<sup>-8</sup> sec. *d*(log *k*)/*dT* is greater for the bimol. than for the unimol. reaction by  $\frac{1}{2}T$ . R. S. B.**

**Limits of inflammability of hydrogen and deuterium in oxygen and in air. W. PAYMAN and H. TITMAN (Nature, 1936, 137, 190).—The upper and lower limits of inflammability of D<sub>2</sub> in O<sub>2</sub> and in air at 1 atm. differ slightly from those of corresponding mixtures with H<sub>2</sub>. L. S. T.**

**Prevention of gas explosions by controlling oxygen concentration.—See B., 1936, 177.**

**Explosion limits. I. Influence of argon, nitrogen, helium, and carbon dioxide on explosion limits of hydrogen, carbon monoxide, methane, and butane in air. II. Occurrence of explosion limits, their dependence on the pressure, and the influence of dilution with an inert gas. J. VAN HEININGEN (Rec. trav. chim., 1936, 55, 65—75, 85—100).—I. The extinguishing action of the four gases is in all cases in the order CO<sub>2</sub> > He > N<sub>2</sub> > A (cf. Coward and Hartwell, A., 1926, 805). Addition of inert gas mainly affects the upper explosion limits, the lower limit depending little on the nature and amount of inert gas. The curves delimiting the explosion region of one particular combustible gas, obtained on the addition of the four inert gases, form a family having a common axis and intersecting only at the two explosion limits for 0% of inert gas.**

**II. A simple mathematical treatment of explosion limits is given without recourse to the theories of chain mechanisms. Assuming that the velocity of**

reaction of two gases  $A$  and  $B$  is bimol. obeying the relation  $s = kC_A C_B$ , where  $s$  is the velocity, the usual curve of the equation  $s = f(x)$ , where  $x$  is the no. of g.-mol. of  $A$  and  $1-x$  is the no. of g.-mol. of  $B$  present in  $v$  litres, is deduced. For certain vals. of  $s$  when reactions become explosive, two explosive limits occur at different concns. The effect of the change of thermal conductivity with concns. shows that the explosive limits are not given by the intersections of the parabola  $s = f(x)$  with a straight line parallel to the  $X$  axis. The conclusion is reached, with certain assumptions, that two explosive limits occur at high pressures and approach one another as the pressure is decreased. Dilution with an inert gas is considered and an equation deduced which covers certain of the experimental results. The sp. action of an inert gas can be explained if it is assumed to influence the reaction const. and an equation is derived for this effect, but if the changes in thermal conductivity are taken into account,  $A$ ,  $N_2$ ,  $He$ , or  $CO_2$  appear to have no appreciable influence on the reaction const.

D. C. J.

**Limits and speeds of detonation of some gaseous mixtures.** J. BRITON and P. LAFFITTE (Compt. rend., 1936, 202, 316—318; cf. A., 1934, 969).—Vals. are given for the upper and lower limits and velocity of detonation for the following mixtures:  $C_3H_8-O_2$ ,  $C_4H_{10}-O_2$ ,  $C_2H_2-O_2$ ,  $C_2H_2$ -air,  $NH_3-O_2$ ,  $Et_2O-O_2$ ,  $Et_2O$ -air, for the effect of pressure (1—8.7 atm.) on the limits for  $H_2-O_2$  and  $H_2$ -air explosions, and for the effect of small additions of  $H_2$  on the lower limit for  $CO-O_2$  mixtures.  $PbEt_4$  has no appreciable influence on the detonation limits.

H. J. E.

**Thermal study of the oxidation of hydrocarbons.** (MLLE.) S. ESTRADÈRE (Compt. rend., 1936, 202, 217—219).—A relationship is determined between inflammation temp. of hydrocarbons and the no. of C atoms; it is considered to run parallel with their octane nos.

T. G. P.

**Temperature and latent energy in flame gases.** W. T. DAVID (Phil. Mag., 1936, [vii], 21, 280—281; cf. A., 1935, 138, 598).—The temp. measured by a thin Pt-Rh wire in the flame gases on combustion at const. pressure of various gas mixtures for which the ideal calc. temp. is  $1900^\circ$  has been recorded. The measured temp. ranges from  $1390^\circ$  to  $1745^\circ$  and corresponds with latent energies of 28—8% of the heat of combustion. Similar data are given for mixtures which have the same measured temp., viz.,  $1550^\circ$ . The long-lived latent energy depends on the nature of the combustible gas and of the diluents, and on the pressure.

R. S. B.

**Thermal decomposition of ethane.** I. Probability of decomposition into two methyl radicals and into ethylene and hydrogen. II. Collision efficiency in activation and mean life in activated state. H. SACHSSE (Z. physikal. Chem., 1935, B, 31, 79—86, 87—104).—I. In the decomp. at  $560$ — $590^\circ$   $[H]$  is  $\sim$  twice as great as corresponds with the equilibrium  $H_2 \rightleftharpoons 2H$  in pure  $H_2$ , showing that part of the  $C_2H_6$  decomposes primarily into Me radicals, which form H atoms by chain reactions.  $[H]$  is, however, only about 0.001 of the val. calc. assuming,

according to the Rice-Herzfeld theory (A., 1934, 369), that all the  $C_2H_6$  decomposes by chain reactions initiated by the formation of Me. Hence only a small part of the  $C_2H_6$  decomposes primarily into radicals.

II. The effect of pressure on the reaction velocity at  $856$ — $910^\circ$  abs. leads to the equation  $\log k = 14.1 - 69,800/2.3RT$  for the velocity at infinite pressure. It appears that deactivation occurs in only 1 in  $\sim 10^{25}$  collisions between an active and a normal mol. The life of an active mol. is  $10^{-6}$  sec. The theory of "kinetically-effective degrees of freedom" (cf. A., 1927, 26) is criticised.

R. C.

**Mechanism of, and constitutional factors controlling, the hydrolysis of carboxylic esters.**

VIII. **Energies associated with induced polar effects in the hydrolysis of substituted benzoic esters.** C. K. INGOLD and W. S. NATHAN (J.C.S., 1936, 222—225).—The rate of alkaline hydrolysis of  $p-C_6H_4X \cdot CO_2Et$ , in which it is assumed that induced polar effects are isolated from local disturbances, has been determined in aq. 85 wt.-% EtOH at  $25^\circ$  and  $50^\circ$ . The velocity coeff.,  $k$ , varies with the substituent,  $X$ , thus,  $NH_2 < OMe < Me < H < Cl < I < Br < NO_2$  over a 5000-fold range. The activation energy,  $E$ , decreases from 20,000 to 15,000 g.-cal. thus,  $NH_2 > OMe > Me > H > \text{halogens} > NO_2$ . The linear relation between  $E$  and  $\log k$  corresponds with a const. val. of  $B$  in  $k = Be^{-E/RT}$ , and the similar relation, considered on the same scale, between existing data for the acid-catalysed bromination of substituted CPhMe (A., 1935, 1209) is not inconsistent with a const. val. of  $B$ .

J. G. A. G.

**Kinetic salt effect in saponification of ester ions.** R. F. NIELSEN (J. Amer. Chem. Soc., 1936, 58, 206—215).—A conductivity method has been used to study the hydrolysis of  $Et_1$  esters of malonic, succinic, and adipic acids, and a photometric comparison method for  $EtHC_2O_4$  and the betaine ester  $(NEt_3 \cdot CH_2 \cdot CO_2Et)ClO_4$  (I). No effect of the distance of the reacting group from the charge was observed for the four homologous ions. The kinetic salt effect for hydrolysis of (I) at ionic strengths down to 0.0001 is that given by the Brönsted-Debye equation for vals. of  $\sqrt{\mu} < 0.1$ .

E. S. H.

**Influence of heavy water on the rate of esterification of benzoic acid in ethyl-alcoholic hydrogen chloride.** A. KAILAN and H. HORNÝ (Ber., 1936, 69, [B], 437—440).—Under like mol. conditions the rate of esterification of  $BzOH$  by EtOH containing HCl is diminished less by  $D_2O$  than by  $H_2O$ .

H. W.

$\alpha\alpha$ -Dimethylacetoacetic acid. Hydrolysis of the ethyl ester. Ketonic decomposition. Reaction with iodine and bromine. Dissociation constant. K. J. PEDERSEN (J. Amer. Chem. Soc., 1936, 58, 240—246).—The rates of (a) hydrolysis of the Et ester at  $0^\circ$  and  $25^\circ$ , (b) ketonic decomp. of the acid in mixtures of HCl and NaCl at  $25^\circ$  and  $35^\circ$ , (c) ketonic decomp. of the ion at  $25^\circ$  and  $35^\circ$ , (d) reaction of the acid with I and Br at  $25^\circ$  have been studied. It is unlikely that the acid reacts directly with halogen; an intermediate enol form is probable. It appears that the  $CO_2$  cleavage of  $\beta$ -ketocarboxylic acids leads directly to the enol form of the reaction

product. This reacts instantaneously with free halogen; in absence of halogen it is transformed into the corresponding ketone. The dissociation const. of the acid in solutions containing NaCl has been determined at 25° and 35°.

E. S. H.

**Course of reaction in the alkaline hydrolysis of solutions of sodium chloroacetate.** H. M. DAWSON and E. R. PYCOCK (Proc. Leeds Phil. Soc., 1935–1936, 3, 135–140; cf. A., 1934, 847).—The alkaline hydrolysis of  $\text{CH}_2\text{Cl}\cdot\text{CO}_2\text{Na}$  (I) in presence of excess of alkali is a bimol. reaction. When excess of (I) is present the reaction of  $\text{CH}_2\text{Cl}\cdot\text{CO}_2'$  with  $\text{H}_2\text{O}$ ,  $\text{CH}_2\text{Cl}\cdot\text{CO}_2'$ , and  $\text{OH}\cdot\text{CH}_2\cdot\text{CO}_2'$  must also be considered.

H. J. E.

**Kinetics of thermal polymerisation of styrene.** H. MARK and R. RAFF (Z. physikal. Chem., 1936, B, 31, 275–291).—The rates of polymerisation of the solution in PhMe at 98.2° and of the pure liquid at 60–98° have been determined. Assuming that the polymerisation consists in (1) a bimol. thermal formation of doubly unsaturated nuclei followed by (2) a bimol. growth of the mol. chains, and applying the theory previously described (A., 1935, 1206), it is deduced that the ratio of the rate of (1) to that of (2) is  $\sim 8 \times 10^{-6}$ , the ratio of the steric factors is  $\sim 7.5 \times 10^{11}$ , and the energies of activation are  $\sim 30$  and  $\sim 8$  kg.-cal., respectively.

R. C.

**Appearance of radicals in thermal decomposition of organic molecules.** F. PATAT and H. SACUSSE (Z. physikal. Chem., 1935, B, 31, 105–124).—In the formation of Me by decomp. of such substances as  $\text{COMe}_2$ , a steady  $[\text{Me}]$  has a corresponding steady  $[\text{H}\cdot]$ , so that the former may be deduced from the latter. In the thermal decomp. of  $\text{MeCHO}$ ,  $\text{EtCHO}$ , and  $\text{COMe}_2$  free Me radicals are formed, but in amount far too small to account for the whole of the decomp. by a chain reaction (cf. A., 1934, 369). The smaller is the difference between the experimentally determined heat of activation and the heat of activation of the first step of the decomp. into radicals, i.e., the energy required to break the weakest linking, the more radicals are formed in a thermal decomp. The decomp. into radicals which involves the simplest spatial rearrangements occurs by preference.

R. C.

**Velocity of formation of compounds of higher order, with special reference to the streaming process for investigating very rapid reactions.** A. THIEL and A. LOGEMANN (Sitzungsber. Ges. Beförd. ges. Naturwiss. Marburg, 1934, 69, 50–188; Chem. Zentr., 1935, i, 2939).—Colorimetric study of the kinetics of the formation of  $[\text{Fe}(\text{phenanthroline})_3]\text{SO}_4$  indicate the initial formation of a 1:1 compound. A streaming method, using photoelectric registration, is described for the investigation of reactions proceeding to completion within  $5 \times 10^{-4}$  sec.

J. S. A.

**Mechanism of aromatic side-chain reactions with special reference to the polar effects of substituents.** VII. **Attack at a saturated carbon atom by a charged ion.** J. W. BAKER and W. S. NATHAN (J.C.S., 1936, 236–241).—The kinetics of the equilibrium  $\text{C}_6\text{H}_4\text{X}\cdot\text{CH}_2\text{Br} + \text{CH}_2\text{Ph}\cdot\text{NC}_5\text{H}_5\text{NO}_3 \rightleftharpoons \text{C}_6\text{H}_4\text{X}\cdot\text{CH}_2\cdot\text{O}\cdot\text{NO}_2 + \text{CH}_2\text{Ph}\cdot\text{NC}_5\text{H}_5\text{Br}$ , where X is H,

*p*-Me, *p*-Et, *p*-Bu', *p*-NO<sub>2</sub>, or  $\text{C}_6\text{H}_4\text{X}$  is 2:4- $\text{C}_6\text{H}_3(\text{NO}_2)_2$ , have been investigated in  $\text{COMe}_2$  at 20° and 40°. The energy of activation (18.4–18.9 kg.-cal.) is independent of X and is identical for the forward and reverse reactions. In all cases the equilibrium is largely displaced towards the left, probably owing to an orientation effect when  $\text{NO}_3'$  attacks the C atom. The velocity coeff. varies with X thus:  $\text{H} < \text{Bu}' < \text{Et} < \text{Me} < \text{NO}_2 < 2:4\text{-(NO}_2)_2$ . The variations fall within a 20-fold range and are accounted for by changes in the probability factor which is of the order of unity (cf. A., 1935, 1208).

J. G. A. G.

**[Addition of bromine to] unsaturated acids.**—See this vol., 454.

**Mechanism of substitution at a saturated carbon atom. VI. Hydrolysis of isopropyl bromide.** E. D. HUGHES, C. K. INGOLD, and U. G. SHAPIRO (J.C.S., 1936, 225–236).—The rate of hydrolysis of  $\text{Pr}^i\text{Br}$  by  $\text{OH}'$  has been determined in aq. 60 and 80 vol.-%  $\text{EtOH}$  at 45–75°. At very low  $[\text{OH}']$ , the kinetically unimol. substitution,  $\text{S}_{\text{N}}1$ , occurs without elimination of  $\text{C}_3\text{H}_6$ , and at higher  $[\text{OH}']$  a bimol. substitution reaction,  $\text{S}_{\text{N}}2$ , supervenes concomitantly with the elimination of  $\text{C}_3\text{H}_6$  in a second-order reaction,  $\text{E}2$ . The temp. coeff. leads to the activation energies:  $\text{S}_{\text{N}}1$  22,690 g.-cal.,  $\text{S}_{\text{N}}2$  20,760,  $\text{E}2$  22,100, and  $\text{S}_{\text{N}}2 + \text{E}2$  21,490 in 60%  $\text{EtOH}$ , and slightly higher vals. in 80%  $\text{EtOH}$ . By adding  $\text{H}_2\text{O}$  to the solvent,  $\text{S}_{\text{N}}1$  is accelerated,  $\text{S}_{\text{N}}2$  is slightly retarded, and  $\text{E}2$  is more strongly retarded. These results accord with theory and the data are not invalidated by the formation of  $\text{EtOPr}^i$ , especially in 80%  $\text{EtOH}$ . The priority of Taylor's mechanism (A., 1935, 1465) is disputed.

J. G. A. G.

**Velocity of decomposition of diazo-compounds in water. XIX.** E. YAMAMOTO (J. Soc. Chem. Ind. Japan, 1936, 39, 15–17B).—*k* of decomp. of azobenzene-*p*-diazonium chloride (I) at 40–50°, and of azo-*o*-toluene-*p*-diazonium chloride (II) at 25–40° have been measured. Relative vals. of stability ( $1/k$ ) of 36 diazo-compounds are tabulated. If  $1/k$  for  $\text{PhN}_2\text{Cl}=1$ , that of (I) is 3.3, and that of (II) 6.2.

E. W. W.

**Influence of degree of acidity on velocity of diazotisation.**—See this vol., 465.

**Hydrolysis of nucleotides by acids.** H. ISHIKAWA (J. Biochem. Japan, 1935, 22, 385–395).—Rates of hydrolysis by dil.  $\text{H}_2\text{SO}_4$  of guanylic, xanthylic, inosinic, and adenylic acids, guanosine and xanthosine, and ribosephosphoric acid were determined.

F. O. H.

**Interaction of light and heavy water with aluminium carbide and calcium phosphide.** R. M. BARRER (Trans. Faraday Soc., 1936, 32, 486–490).—The decomp. of  $\text{Al}_4\text{C}_3$  by liquid  $\text{H}_2\text{O}$  has an apparent energy of activation of 14,200 kg.-cal. The reaction rates for  $\text{H}_2\text{O}$  and  $\text{D}_2\text{O}$  are in the ratio 3.9:1 at 273° abs., corresponding with a zero-point energy difference of 750 g.-cal. There is no evidence of a tunnelling mechanism at this temp. The decomp. of  $\text{Ca}_3\text{P}_2$  by  $\text{H}_2\text{O}$  vapour is governed by a diffusion

process. The rates of decomp. by  $\text{H}_2\text{O}$  and  $\text{D}_2\text{O}$  vapours are in the ratio of the v.p. of  $\text{H}_2\text{O}$  and  $\text{D}_2\text{O}$ .

O. J. W.

**Rates of interaction of proto- and deuterio-hydrogen and methane with charcoal.** R. M. BARRER (Trans. Faraday Soc., 1936, 32, 481—486).—The rates of chemisorption of  $\text{H}_2$  and  $\text{D}_2$  and of  $\text{CH}_4$  and  $\text{CD}_4$  on charcoal have been measured. The differences in rate of sorption are due to zero-point energy differences, which are 770 and 750 g.-cal., respectively. The expression  $k_{\text{H}_2}/k_{\text{D}_2} = Ae^{-\Delta E/RT}$  gave a val. of  $A=1$ . No penetration of energy barriers could be detected. The ratio of the velocities decreased in both sorptions with rise in temp.

O. J. W.

**Oxidation of carbon.** J. D. LAMBERT (Trans. Faraday Soc., 1936, 32, 452—462).—The kinetics of the oxidation of several kinds of C have been investigated at 250—500° by a dynamic method, in order to distinguish between the two types of process which are possible, viz., (1) direct formation of  $\text{CO}_2$  by impact of  $\text{O}_2$  mols. on a clean C surface, and (2) primary formation of both  $\text{CO}_2$  and CO by the breakdown of surface oxide complexes. Pure graphite and diamond showed only process (1), activated coconut charcoal showed (1) with a trace of (2), and activated anthracite, containing much Fe, showed only (2). Treatment of coconut charcoal with  $\text{FeCl}_3$  under suitable conditions gave a product closely resembling anthracite in its behaviour on oxidation.

O. J. W.

**Kinetics of the oxidation of spherules and metallic powders.** G. VALENSI (Compt. rend., 1936, 202, 309—312; cf. A., 1935, 1466).—An expression is developed for the rate of oxidation of a solid, the grains of which are protected by oxide films. Measurements on the oxidation of powdered Ni support the theory. The oxidation of non-spherical particles may be considered in terms of an "equiv. sphere."

H. J. E.

**Velocity of corrosion of duralumin.**—See B., 1936, 200.

**Reactions in monolayers of drying oils. I. Oxidation of the maleic anhydride compound of  $\beta$ -elæostearin.** G. GEE and E. K. RIDEAL. II. **Polymerisation of the oxidised forms of the maleic anhydride compound of  $\beta$ -elæostearin.** G. GEE (Proc. Roy. Soc., 1935, A, 153, 116—128, 129—141).—I. The mechanism of "drying" of a monolayer of the maleic anhydride compound of  $\beta$ -elæostearin on dil. acid substrates has been examined by means of a determination of the surface pressure and phase boundary potentials. A primary unstable peroxide,  $\text{XO}_2'$ , is first formed, which can then form either a stable isomeride,  $\text{XO}_2$ , or be converted into a polymeride; the stable isomeride is also capable of forming the polymeride. At low temp. and high pressures the polymerisation of  $\text{XO}_2'$  occurs so rapidly that the whole reaction is pseudo-unimol. At higher temp. and pressures of the order of 5—6 dynes per cm. the two processes can be observed to proceed successively. The reactions  $\text{X} \rightarrow \text{XO}_2' \rightarrow \text{XO}_2$  are unimol. with energies of activation of 6500 and 19,000 g.-cal. per mol., respectively.

II. The kinetics of polymerisation are discussed; a steric factor alone is sufficient to account for the form of the curves obtained. Chain-breaking materials may be (a) inserted in the substrate like quinol, or (b) inserted in the film itself like Etmyristate. The polymerisations of the unstable peroxide and of its stable isomeride have energies of activation of the order of 5000 and 20,000 g.-cal. per mol., respectively.

L. L. B.

**Influence of constitution of the oxidised substances on the activity of catalysts for oxidation by concentrated sulphuric acid, and influence of temperature on the catalysts.** J. MILBAUER (Bull. Soc. chim., 1936, [v], 3, 218—221).—Tests with numerous catalysts for the Kjeldahl reaction show that the efficiency of the catalyst depends on the constitution of the substance to be oxidised, and on the temp.

E. S. H.

**Autoxidation. V. Induction period in autoxidation.** H. N. STEPHENS (J. Amer. Chem. Soc., 1936, 58, 219—224; cf. A., 1934, 607).—A study of the effect of purification and the influence of addenda shows that the induction period in the autoxidation of cyclohexene is due to the presence of inhibitors.

E. S. H.

**Oxidation of aqueous sulphite solutions in presence of pyridine. II. Autoxidation of aqueous sulphite solutions. Mechanism of sulphite autoxidation.** P. BAUMGARTEN (Ber., 1936, 69, [B], 229—242; cf. A., 1932, 1216).—Autoxidation of  $\text{SO}_3''$  in presence of  $\text{C}_5\text{H}_5\text{N}$  gives 1-pyridinium-sulphonic acid and small amounts of 2- and 3-pyridyl-pyridinium salts isolated as the perchlorates. In presence of sufficient  $\text{C}_5\text{H}_5\text{N}$  the yields diminish with increasing  $[\text{SO}_3'']$ , and reaction is best effected by passing a stream of air slightly laden with  $\text{SO}_2$  through a well-stirred solution of  $\text{C}_5\text{H}_5\text{N}$  in  $\text{H}_2\text{O}$ . The change does not occur in absence of air. Unlike  $\text{EtOH}$ ,  $\text{C}_5\text{H}_5\text{N}$  accelerates the autoxidation of  $\text{HSO}_3'$  owing to the increase of  $[\text{SO}_3'']$  which it causes. In the initial stages of the change autoxidation of  $\text{SO}_3''$  by  $\text{C}_5\text{H}_5\text{N}$  is not restricted, but subsequently such effect is obvious, due to increase of  $[\text{OH}']$ . Inhibition occurs only within narrow  $p_{\text{H}}$  range. The theories of  $\text{SO}_3''$  autoxidation are discussed.

J. G. A. G.

**Conjugated catalytic phenomena. [Catalysis by binary and ternary mixtures.]** J. MILBAUER (Coll. Czech. Chem. Comm., 1936, 8, 1—12).—The catalysis of the oxidation of CO by 95.6%  $\text{H}_2\text{SO}_4$  at 237° has been investigated by a flow method. The final rate of oxidation catalysed by mixtures of

As and Se oxides is independent of As oxides and  $\propto [\text{SeO}_2]$ . Pd is a very strong catalyst, of which the action is enhanced by  $\text{HgSO}_4$  and raised to a max. by 10–30% of  $\text{Ag}_2\text{SO}_4$ , but is markedly depressed by Se. Sp. proportions of  $\text{HgSO}_4$  and  $\text{Ag}_2\text{SO}_4$ , separately, raise the catalytic activity of  $\text{SeO}_2$  to max. vals. Mixtures of  $\text{HgSO}_4$  and  $\text{Ag}_2\text{SO}_4$  are better catalysts than the single salts, whilst an approx. 1:4  $\text{CuSO}_4$ – $\text{HgSO}_4$  mixture has a max. catalytic activity. The effect on the reaction velocity of varying the composition of ternary catalysts is represented quantitatively by triangular diagrams. Catalysis by the systems Pd+Se+Ag, Hg+Se+Ag, Pd+Hg+Ag, Cu+Hg+Se was < the max. vals. obtained with the binary systems. J. G. A. G.

**Catalytic interaction of ammonia with deuterium.** A. FARKAS (Trans. Faraday Soc., 1936, 32, 416–427).—The exchange of H atoms between  $\text{D}_2$  and  $\text{NH}_3$  has been investigated on an Fe catalyst at 160–230°/30–400 mm. The rate of the exchange reaction is independent of  $\text{NH}_3$  pressure and increases with pressure of  $\text{D}_2$ . The apparent heat of activation is 15 kg.-cal. The *o-p* conversion of  $\text{H}_2$  and of  $\text{D}_2$  and the reaction  $\text{H}_2 + \text{D}_2 = 2\text{HD}$  are much faster than the exchange reaction. For the *o-p* conversions the activation energy is 8–9 kg.-cal. The conversion is inhibited by  $\text{NH}_3$ . The exchange reaction proceeds by the following reactions in the adsorption layer:  $\text{NH}_3 \rightarrow \text{NH}_2 + \text{H}$ ,  $\text{D}_2 \rightarrow 2\text{D}$ ,  $\text{D} + \text{H} \rightarrow \text{HD}$ ,  $\text{D} + \text{NH}_2 \rightarrow \text{NH}_2\text{D}$ . The last of these is the slowest and rate-determining step. O. J. W.

**Thermal decomposition of light and heavy ammonia and phosphine on tungsten.** R. M. BARRER (Trans. Faraday Soc., 1936, 32, 490–501).—Velocity measurements have been made for the thermal catalytic decomp. on W filaments ( $\alpha$ ) of  $\text{NH}_3$  between  $6 \times 10^{-2}$  and  $6 \times 10^{-4}$  cm. and 950–1150° abs., and ( $\beta$ ) of  $\text{PH}_3$  between  $10^{-1}$  and  $2 \times 10^{-4}$  cm. and 800–970° abs. On various W catalysts and in the early stages of the reaction ( $\alpha$ ) was of zero order, but towards the end of decomp. or at the lowest *p* the velocity diminished as the  $\text{NH}_3$  pressure decreased. Reaction ( $\beta$ ) was of first order at  $p = 10^{-4}$  to  $5.0 \times 10^{-3}$  cm. and became of approx. zero order at about  $10^{-1}$  cm. The rate-determining step in both reactions involves a rearrangement of a H linking, since differences were found in zero-point energy of 800–900 g.-cal. for  $\text{NH}_3$  and  $\text{ND}_3$ , and 550 g.-cal. for  $\text{PH}_3$  and  $\text{PD}_3$ .  $\text{H}_2$  and  $\text{N}_2$  have no influence on the rate of catalytic decomp. of  $\text{NH}_3$ , but  $\text{O}_2$  produces a temporary poisoning of the catalyst. The energies of activation, measured by a compensating filament method, are 42,400 g.-cal. for the zero order  $\text{NH}_3$  decomp., 25,000 g.-cal. for the first order and 32,200 g.-cal. for the zero order  $\text{PH}_3$  decomp. O. J. W.

**Siderite as basic material for the catalytic synthesis of ammonia.**—See B., 1936, 190.

**Centrifugal transformation of a thin layer of copper sulphide under the influence of metallic copper; interruption of this transformation by a separation of 1 Å.** H. DEVAUX (Compt. rend., 1935, 201, 1305–1307).—A piece of Cu, Fe, Zn, Ni, Al, or Sn placed in contact with the thin layer of  $\text{CuS}$

deposited on the surface of aq.  $\text{CuSO}_4$  by  $\text{H}_2\text{S}$  induced a change which ultimately extended some distance around the metal. The reaction ceased when the film was so thin that the mols. were judged to be 0.6–1.0 Å. apart. The rate of the reaction  $\propto \sqrt{\text{temp.}}$  (approx.). T. G. P.

**Catalytic reduction of carbon dioxide to methane and higher hydrocarbons.**—See B., 1936, 180.

**[Catalytic] synthesis of *n*-heptane.**—See B., 1936, 181.

**Properties of the methyl alcohol catalyst copper-zinc oxide-chromic oxide.**—See B., 1936, 191.

**$\psi$ -Halogenes. XXXI. Detection of iodine-mixed halogens by measurements of the rate of reaction between cyclohexene and iodine in the presence of salts of the heavy metals.** L. BIRKENBACH, J. GOUBEAU, and H. G. KRALL (Ber., 1936, 69, [B], 476–484).—The reaction between I and cyclohexene in  $\text{PhMe}$ ,  $\text{CCl}_4$ , or  $\text{Et}_2\text{O}$  occurs very much more rapidly in the presence of  $\text{AgNO}_3$ ,  $\text{AgNCO}$ ,  $\text{AgClO}_4$ , or  $\text{PbCl}_2$  than in their absence. The dependence of the rate on the nature of the metallic salt is explicable on the basis of catalysis, which, however, does not account for the effect of the quantity of salt. The change is therefore attributed to the intermediate formation of mixed halogens:  $\text{I}_2 + \text{RHal}(\psi\text{-hal}) \rightarrow \text{IHal} \rightarrow (+>\text{C}:\text{C}<)>\text{Cl-CHal}<$ . H. W.

**Existence of a sharp temperature threshold for catalytic decomposition of molecules on a hot platinum surface, and the nature of this decomposition.** O. BEECK (Physical Rev., 1934, [ii], 46, 331–332).—Decomp. of mol. beams of hydrocarbons projected on to a Pt strip filament have been investigated. Decomp. of  $\text{C}_2\text{H}_6$  commences at approx. 800° and increases up to 1200° when all impinging mols. are dehydrogenated to  $\text{C}_2\text{H}_4$  and  $\text{H}_2$ .  $\text{C}_2\text{H}_4$  shows no decomp. below 830°, but at 850° every impinging mol. yields  $\text{C}_2\text{H}_2$  and  $\text{H}_2$ . L. S. T.

**Dehydrogenation and dehydration catalysed by nickel-aluminium oxide catalysts.** A. A. BALANDIN and A. M. RUBINSTEIN (Z. physikal. Chem., 1936, B, 31, 195–213; cf. A., 1935, 1348).—The parallel dehydrogenation and dehydration of isoamyl alcohol and the secondary decomp. of the aldehyde formed have been studied. Catalysts prepared by pptg. mixtures of Ni and Al salts with  $\text{NaOH}$  are more active than those pptd. with  $\text{Na}_2\text{CO}_3$ . Catalysts prepared from chlorides and sulphates may be as active as the most active catalysts prepared from nitrates. The ratio of the energy of activation of dehydrogenation to that of dehydration averages 0.51, the corresponding vals. for dehydrogenation: aldehyde decomp. and dehydration: aldehyde decomp. being 0.69 and 1.26, respectively. All three ratios vary little from one catalyst to another, but the heats of activation themselves vary considerably. The relation between the energy of activation and the coeff. *a* of Arrhenius' equation previously noted (A., 1933, 234) is valid for both dehydration and dehydro-

generation. It appears that the activity of a mixed catalyst is located at the lines of contact between its components. R. C.

**Asymmetric main valency catalysts.**—See this vol., 476.

**Hydrogenation of ketones.**—See this vol., 457.

**Catalytic reduction of aromatic carboxylic acid esters under high pressure and temperature.** K. MITSUI (Mem. Coll. Sci. Kyoto, 1935, A, 18, 329—336).—The reductions were effected by  $H_2$  at 100 atm. in the presence of reduced Ni. EtOBz reacts rapidly at 150—190° and the product contains 90 mol.-% of Et hexahydrobenzoate;  $CH_2Ph\cdot OH$  and BzOH were not produced. The product from  $CH_2Ph\cdot CO_2Et$  at >140° contains 90 mol.-% of Et cyclohexylacetate. The product from Et salicylate at >200° contains 75 mol.-% of cyclohexanol, cyclohexane, and EtOH.  $m\text{-OH}\cdot C_6H_4\cdot CO_2Et$  at 170—190° absorbs 3 mols. of  $H_2$  forming products containing 75 mol.-% of Et *m*-hydroxyhexahydrobenzoate, and  $p\text{-OH}\cdot C_6H_4\cdot CO_2Et$  at 180—200° absorbs 2 mols. of  $H_2$  forming products containing 40 mol.-% of Et *p*-hydroxyhexahydrobenzoate. J. G. A. G.

**Electrolytic separation of deuterium.** A. J. EDWARDS, H. F. WALTON, R. P. BELL, and J. H. WOLFENDEN (J.C.S., 1936, 286—287).—Vals. of the separation coeff.,  $\alpha$ , obtained by protracted electrolysis of aq. NaOH containing 0.5—1%  $D_2O$  under apparently identical conditions fluctuate widely. Vals. of  $\alpha$  for different cathode materials are recorded. J. G. A. G.

**Electrolytic formation of persulphate.** I. R. MATSUDA (Bull. Chem. Soc. Japan, 1936, 11, 1—7).—Aq.  $[NH_4]_2SO_4$  and  $H_2SO_4$ , in which the ratio of the normalities varied from 0:10 to 8:2, have been electrolysed at different c.d. and the variation of current efficiency for the formation of  $S_2O_8^{2-}$  examined. Current efficiency increases with c.d., the effect being greatest in the more acid solutions; it also increases as  $[H_2SO_4]$  diminishes and the effect at low c.d. is > at high. Increase in total concn. for a const. 5:1 ratio raises the efficiency, especially at higher c.d. The results indicate that increase in  $[OH^-]$  favours anodic oxidation. The effect of replacement of  $NH_4^+$  by other cations has been investigated. Current efficiency for  $K^+$ ,  $Na^+$ , and  $NH_4^+$ , which form acid sulphates, is > for the other cations, viz.,  $Mg^{2+}$ ,  $Li^+$ ,  $Al^{3+}$ ,  $Cd^{2+}$ ,  $Fe^{3+}$ ,  $Cu^{2+}$ , and  $Zn^{2+}$ ; it is greatest for  $K^+$ , but the catalytic decomp. of  $S_2O_8^{2-}$  by cations is in the order  $Na^+ > K^+ > NH_4^+$ . M. S. B.

**Electrical synthesis of nitric oxide.** J. WILLEY (Nature, 1936, 137, 274—275).—With a 1:1 mixture of  $N_2$  and  $O_2$  the yield of NO at 5—10 mm. pressure with rapid gas circulation is practically independent of the electrical power supplied. A liquid air trap placed near the discharge condenses 7 to 10 times more  $NO_2$  than one placed at a distance from it, although the equiv. time interval is only 0.05 sec. This effect disappears when a plug of oxidised Cu is placed between the discharge and the trap, or when a large excess of  $O_2$  is used. It is apparently due to the simultaneous formation of active N which decomposes much of the NO formed. L. S. T.

**Simultaneous discharge of  $Cd^{2+}$  and  $H^+$  ions in solutions of simple salts of cadmium.** O. ESSIN, F. BEKLEMISHEVA, and A. MATANZEV (J. Chim. phys., 1936, 33, 72—77).—The yield of Cd obtained by electrolysis of aq.  $CdSO_4$  has been studied at 25° for  $[H_2SO_4]$  0.1N—10N and  $[CdSO_4]$  0.125N—1N and with c.d. 0.25—1 amp. per sq. dm. The results are in accord with the equation of simultaneous discharge calc. from Volmer's theory of overpotential. J. W. S.

**Electrolytic separation of bivalent europium.** A. BRUKL (Angew. Chem., 1936, 49, 159—161).—Eu can be readily separated by electrolytic reduction at a Hg cathode. For mixtures of rare earths containing < 2%  $Eu_2O_3$  it is necessary to co-ppt. the Eu (as  $EuSO_4$ ) with  $SrSO_4$  (cf. Selwood, A., 1935, 950), the  $SrSO_4$  being then removed by dissolution in hot 50% HCl, and further purification effected through pptn. with  $H_2C_2O_4$ . Sa mother-liquors containing 1—1.2%  $Eu_2O_3$  were electrolysed using c.d. of 0.1 amp. per sq. cm. (0.12 amp. per sq. cm. gave Sr-Hg), and after 8 electrolyses and subsequent separation of  $SrSO_4$ , the Eu content increased to 30%. Three further electrolyses without  $SrSO_4$  gave a product containing 99.40%  $Eu_2O_3$ , the impurities being Sa 0.5, Gd 0.03, and Yb 0.02%. The yield was 12 g. from 1.5 kg. of mother-liquor containing 1—1.2%  $Eu_2O_3$ . D. C. J.

**Mechanism of electrolytic processes. I. Anodic oxidation of some metals of the platinum group.** J. A. V. BUTLER and G. DREVER. II. **Electrolytic oxidation of sodium sulphite.** J. A. V. BUTLER and W. M. LESLIE (Trans. Faraday Soc., 1936, 32, 427—435, 435—444).—I. When electrodes of Pd, Rh, and Ir are anodically polarised in acid and alkaline solutions, an adsorbed layer of O is formed prior to the establishment of the O overvoltage, as in the case of Pt (cf. A., 1932, 1092; 1934, 154). With Pd and Rh the slow formation of peroxidic oxides has been observed as the second stage in the oxidation. These oxides are reduced cathodically at a more positive potential than the adsorbed O, and the conditions of their formation have been studied. A mechanism of the anodic oxidation of insol. metals is suggested.

II. The electrolytic oxidation of  $Na_2SO_3$  at Pt electrodes in buffer solutions of various  $p_H$  has been investigated. With  $p_H$  7 the oxidation takes place at a more negative potential than that at which adsorbed O is formed. Since no other primary process is observed in this region with the buffer solution alone, oxidation probably takes place in solutions of this  $p_H$  by direct transfer of electrons from the  $SO_3^{2-}$  ions to the electrode. With  $p_H$  9 oxidation occurs in the same region as that in which adsorbed O is formed, so that oxidation by adsorbed O is possible. The effect of adding various salts has been studied. With  $Mn^{2+}$  salts, which are the most effective, suppression of the initial stage of electrolysis is due to the formation of a film of  $MnO_2$ . The results do not agree with Glasstone and Hickling's theory (cf. A., 1933, 913) and an alternative mechanism is suggested. O. J. W.

**Effect of anode composition on zinc electrolysis.**—See B., 1936, 201.

**Electrolytic lead-plating.**—See B., 1936, 201.

**Electroplating bismuth on metals.**—See B., 1936, 201.

**Photochemical union of hydrogen and chlorine.**  
**IV. Reaction at low hydrogen pressures. Effects of wave-length, of temperature, and of traces of oxygen.** H. C. CRAGGS and A. J. ALLMAN (J.C.S., 1936, 241—252).—By irradiating O<sub>2</sub>-free mixtures of 0.1—0.6 mm. of H<sub>2</sub> and 1.7—166 mm. of Cl<sub>2</sub> with monochromatic light of  $\lambda$  546 m $\mu$ , HCl is formed, and the temp. coeff. leads to the activation energy 9.78 kg.-cal. (cf. 4.74—5.5 at  $\lambda$  436 m $\mu$ ). No HCl was obtained at  $\lambda$  579 m $\mu$ . The quantum efficiency,  $\gamma$ , relative to unity at 436 m $\mu$  is approx. 0.3 at 546 m $\mu$ . These results may be correlated with the continuous background of the banded spectrum region of Cl<sub>2</sub>. Thus, Cl<sub>2</sub> mols. in high vibration levels absorbing at  $\lambda$  546 m $\mu$  acquire sufficient additional energy to dissociate into atoms which initiate reaction chains. At approx. 2 mm. total pressure, ultra-violet light affords vals. of  $\gamma$  < with visible light, but at higher pressures this difference was not observed. Cl<sub>3</sub> formed by light of short  $\lambda$  would account for these results. 0.1 mm. of O<sub>2</sub> retards the reaction between Cl<sub>2</sub> and < 0.01 mm. H<sub>2</sub>, but has no effect when there is 0.5—0.01 mm. H<sub>2</sub>, although O<sub>2</sub> is consumed. These effects are discussed. J. G. A. G.

**Properties of illuminated iodine solutions.**  
**I. Photochemical dissociation of iodine molecules in solution.** E. RABINOWITCH and W. C. WOOD (Trans. Faraday Soc., 1936, 32, 547—556).—Improvement of the apparatus previously described (A., 1935, 586) has permitted the detection and measurement of a reversible change in the extinction coeff. ( $\epsilon$ ) of I solutions under the influence of strong illumination. In CCl<sub>4</sub> and C<sub>6</sub>H<sub>14</sub>  $\epsilon$  decreases under illumination owing to dissociation of I<sub>2</sub> mols. into atoms. The velocity of recombination of the latter in solution is about 1000 times > that of Br atoms in He at atm. pressure, agreeing with the assumption that triple collisions are necessary in gas and that in solution every collision is effective. The quantum yield for dissociation of I<sub>2</sub> in solution is the same in the continuous spectral region as in the band region. Explanations of the results are offered. F. L. U.

**Detection of a latent image in thalious bromide.** W. J. G. FARRER (Nature, 1936, 137, 276).—Emulsions of TlBr in gelatin can receive a latent image, but direct reduction of the exposed bromide to Tl is not possible. By treatment with aq. AgNO<sub>3</sub> the Tl in the emulsion is replaced by Ag without destruction of the latent image, and after removal of the excess of sol. Ag the plate can be developed and fixed in the usual way. Replacement of the Tl by Ag occurs apparently without alteration in crystal shape or structure. TlBr emulsions can be colour-sensitised with dyes in the same way as Ag emulsions, but the same high degree of sensitivity has not yet been reached. L. S. T.

**Free *n*-propyl radical.**—See this vol., 451.

**Photodecomposition of iodoform and of alkyl and alkylene iodides.** K. E. GIBSON and T. IREDALE (Trans. Faraday Soc., 1936, 32, 571—576;

cf. A., 1933, 553).—The quantum yield in the photochemical production of I by C<sub>6</sub>H<sub>6</sub> solutions of MeI, CH<sub>2</sub>I<sub>2</sub>, Bu<sup>n</sup>I, CH<sub>3</sub>Bu<sup>n</sup>I, and C<sub>16</sub>H<sub>33</sub>I has been determined at room temp. and in absence of O<sub>2</sub>. For MeI and Bu<sup>n</sup>I the yield is approx. 1, and for the others 0.55—0.75. MeI in EtOH gives a val. > 1. The results are discussed. F. L. U.

**Photochemical decomposition of gaseous methyl iodide alone and in presence of hydrogen and nitrous oxide.** R. SPENCE and W. WILD (Proc. Leeds Phil. Soc., 1935—1936, 3, 141—144; cf. A., 1931, 1138).—Irradiation of MeI yielded CH<sub>4</sub>, C<sub>2</sub>H<sub>6</sub>, and I. Increased yields of CH<sub>4</sub> were not obtained in presence of H<sub>2</sub>. The approx. quantum yield of CH<sub>4</sub> formation in terms of MeI disappearing was 0.06. There was no detectable reaction between Me and N<sub>2</sub>O. H. J. E.

**Photochemical formation of organic diradicals.**

**III. Anthracene, the fulgides, thiophosgene, and their derivatives.** A. SCHÖNBERG (Trans. Faraday Soc., 1936, 32, 514—521; cf. A., 1935, 986).—In order to explain the different chemical properties of irradiated solutions of certain anthracenes, fulgides, and CSeCl<sub>2</sub> in comparison with those of non-irradiated solutions, a photoequilibrium between the normal and diradical forms of the mol. is assumed, as was done in the case of rubrene (cf. A., 1934, 643). The phenomena of photo-oxidation, photoisomerisation, and photopolymerisation can be accounted for by this means. Objections to the theory are discussed. O. J. W.

**Behaviour of *dl*-serine, *dl*-phenylalanine, *dl*-alanine, *dl*-lactic acid, and propionic acid towards X-rays and ultra-violet light.** J. P. BECKER (Strahlenther., 1935, 52, 537—544; Chem. Zentr., 1935, ii, 203).—The decomp. of *dl*-serine (I) and *dl*-lactic acid (II) follows a different course from that of *dl*-alanine (III) and EtCO<sub>2</sub>H; this is ascribed to the presence of an  $\alpha$ -OH in (I) and (II). *dl*-Phenylalanine also differs from (III) in its mode of decomp. The physiological action of X-rays and ultra-violet light is, in part, attributed to such action. H. N. R.

**Comparison of the photochemical decomposition of *l*-aspartic acid, *l*-asparagine, and glycylglycine by X-rays and ultra-violet light.** J. P. BECKER (Strahlenther., 1935, 52, 531—536; Chem. Zentr., 1935, ii, 203).—Both *l*-aspartic acid and *l*-asparagine yield MeCHO on irradiation with X-rays or ultra-violet light; the decomp. products of glycylglycine are different. H. N. R.

**Photolysis of aliphatic aldehydes. III. Hydrogen from acetaldehyde.** F. E. BLACET and J. G. ROOF (J. Amer. Chem. Soc., 1936, 58, 278—280; cf. A., 1933, 930; 1934, 1188).—The fraction of mols. yielding H<sub>2</sub> increases linearly from 10% at  $\lambda$  3130 to 31% at  $\lambda$  2537. The mechanism of the primary process appears to be:  $\text{RHCO} + h\nu \rightarrow \text{R} + \text{HCO}$ . E. S. H.

**Photochemical reactions of cellulose. IV. Relation between wave-length and strength of light from a quartz mercury vapour lamp.** S. OGURI (J. Soc. Chem. Ind. Japan, 1936, 39, 35—

36B).—A table shows the deflexions of a thermopile galvanometer at  $\lambda$  of 2000—7000 Å. A. G.

**Concentrations of sodium vapour in the electric arc.** T. PECZALSKI and N. SZULC (Compt. rend., 1935, 201, 1335—1337; cf. A., 1935, 1046).—The concns. of Na within and around a C arc burning in the presence of NaCl have been determined spectroscopically. T. G. P.

**Significance of potassium carbonate for the corrosive action of potassium cyanide.** H. ELBEL (Z. ges. gerichtl. Med., 1934, 24, 25—29; Chem. Zentr., 1935, i, 3951—3952).—The corrosive action of KCN depends on its alkaline properties, and is weakened rather than strengthened by  $K_2CO_3$ . R. N. C.

**Rubidium and caesium fulminates.** L. HACKSPILL and W. SCHUMACHER (Compt. rend., 1936, 202, 69—71).—The fulminates were prepared by treating the alkali-metal amalgam, prepared in vac., with a suspension of Hg fulminate in anhyd. MeOH, and pptg. the salt with anhyd.  $Et_2O$ . Dissolution in MeOH and repptn. with  $Et_2O$  is necessary to remove traces of the double fulminate of Hg and Rb or Cs. The latter renders the product liable to detonate at  $< 50^\circ$ . H. J. E.

**Caesium mercury iodide.** F. GALLAIS (Compt. rend., 1936, 202, 54—56; cf. A., 1935, 592).—Measurements of electrical conductivity and of magnetic rotatory power are recorded for mixed solutions of CsI and  $HgCl_2$  in  $H_2O$  or EtOH. The formation of  $Cs_2HgI_4$  is indicated in 0.01—0.5M solutions. H. J. E.

**Basic copper sulphates.** O. BINDER (Ann. Chim., 1936, [xi], 5, 337—409).—A more detailed account of work previously described (this vol., 38, 172).  $4CuO \cdot SO_3 \cdot 4H_2O$  at  $150^\circ$  gives  $4CuO \cdot SO_3 \cdot 3H_2O$ , the X-ray photograph of which resembles that of  $4CuO \cdot SO_3 \cdot 4H_2O$ . The four basic sulphates are formulated  $[Cu\{(OH)_2Cu\}_3SO_4 \cdot H_2O]$ ;  $[Cu\{(OH)_2Cu\}_3SO_4]$ ;  $[Cu\{(OH)_2Cu\}_2SO_4]$ , and  $[Cu \cdot O \cdot Cu]SO_4$ . The first three are identified with langite, brochantite, and antlerite (stolznerite), respectively. F. R. G.

**Yellow cuprous oxide.** G. R. LEVI (Z. anorg. Chem., 1936, 226, 173—174).—A claim for priority over Straumanis *et al.* (A., 1935, 1332) with reference to the proof of the direct formation of  $Cu_2O$  by reduction in aq. solution. M. S. B.

**Organic cupri-tetrachlorides and -tetrabromides formed by secondary and tertiary amines and alkaloids.** J. AMIEL (Compt. rend., 1935, 201, 1383—1385; cf. this vol., 212).—The following compounds have been prepared and in some cases their *d* and solubilities determined:  $CuCl_4(NH_2Et)_2$ ,  $CuCl_4(NHEt)_2$ ,  $CuBr_4(NH_2Et)_2$ ,  $CuCl_4(NH_2PhMe)_2$ ,  $CuCl_4(NH_2PhEt)_2$ ,  $CuCl_4(NHPhMe)_2$ ,  $CuCl_4(NHPhEt)_2$ ,  $CuBr_4(NH_2PhMe)_2$ ,  $CuBr_4(NH_2PhEt)_2$ ,  $CuBr_4(NHPhMe)_2$ ,  $CuBr_4(NHPhEt)_2$ ; with nicotine, quinine, and strychnine  $CuCl_4(C_{10}H_{14}N_2H_2) \cdot H_2O$ ,  $CuCl_4(C_{10}H_{14}N_2H_2)$ ,  $CuCl_4(C_{20}H_{24}N_2O_2H_2)$ ,  $CuCl_4(C_{21}H_{24}N_2O_2H_2)$ ,  $CuBr_4(C_{10}H_{14}N_2H_2)$ ,  $CuBr_4(C_{20}H_{24}N_2O_2H_2)$ , and  $CuBr_4(C_{21}H_{24}N_2O_2H_2)_2$ ; and with brucine  $CuCl_4(C_{23}H_{26}N_2O_4H_2)$ . T. G. P.

**Silver solutions containing iodine.** (MLLE.) M. L. JOSIEN (Ann. Chim., 1936, [xi], 5, 147—265).—The action of aq. I on aq.  $AgNO_3$  comprises a rapid reaction between the HI produced by hydrolysis of the I and  $Ag^+$ , yielding insol.  $AgI$ , followed by decomp. of the  $HOI$  to give HI and  $HIO_3$ . The latter reaction is slow, being accelerated by increasing salt concn., by rise of temp., and by addition of acid. The reaction is most rapid when the Ag salt of a strong acid is used in the reaction. The reduction of  $IO_3^-$  by HCl and  $As_2O_3$  is attributed to a cyclic reaction, probably with intermediate production of I and oxidation of the  $As_2O_3$ , rather than to catalytic action. Sparingly sol. Ag salts react with I similarly to  $AgNO_3$ , but the first step is not instantaneous. The reaction between  $AgCl$  and I is not a direct substitution, but  $3I_2 + 5AgCl + 3H_2O = 5AgI + HIO_3 + 5HCl$ . It is concluded that there is no evidence of production of an intermediate product between  $OI^-$  and  $IO_3^-$  in the reaction between I and Ag salts or between I and alkali. J. W. S.

**Solid reactions at 1000—1200° between magnesium oxide or beryllium oxide and nickel, iron, chromium, manganese, and their oxides.** L. NAVIAS (J. Amer. Ceram. Soc., 1936, 19, 1—7).—The reactions were carried out with the mixtures as loose and pressed powders and with loose powder on a high-fired pressed slab of MgO or BeO. The degree of reaction was noted by the extent of discoloration at the interface. In an oxidising atm. at 1200° the reaction with MgO and BeO increased in the order NiO (with BeO, none),  $Fe_2O_3$ ,  $Cr_2O_3$ ,  $MnO_2$ , in all cases reaction with MgO being the greater. The same sequence was found for the metallic elements in an oxidising atm., but the degree of reaction was  $>$  with the corresponding oxides. In a  $H_2$  atm. at 1200° only  $MnO_2$  showed any reaction, and of the metals, Cr and Mn oxidised with very slight reaction. Mixtures of oxides and of metals showed less reaction than the individuals. Wet air gave most reaction between MgO and Mn,  $MnO_2$ , or Cr powders. J. A. S.

**Double salt,  $K_2Mg(CO_3)_2 \cdot 4H_2O$ .** F. HALLA (Z. anorg. Chem., 1936, 226, 139—140).—On gradual addition of aq.  $K_2CO_3$  to aq.  $MgCl_2$ , of suitable concn., reaction takes place in two stages, a flocculent ppt. of  $MgCO_3 \cdot 3H_2O$  being first formed. This redissolves and, as the addition of aq.  $K_2CO_3$  continues, a cryst. ppt. of  $K_2Mg(CO_3)_2 \cdot 4H_2O$  is obtained. Solubility determinations have been made at  $17^\circ$  in aq. KCl of varying concn. to reduce hydrolysis. The temp. coeff. of solubility has also been determined. M. S. B.

**Production of calcium sulphate hemihydrate in the wet way, and the polymorphism of the anhydrous sulphate.** P. GAUBERT (Bull. Soc. franç. Min., 1934, 57, 252—267; Chem. Zentr., 1935, i, 3523).— $CaSO_4 \cdot 0.5H_2O$  was obtained as hexagonal prisms by evaporation of a hot  $HNO_3$  solution of  $CaSO_4$ . When dehydrated in air at  $130^\circ$ , or in a neutral liquid at  $170^\circ$ , they maintain their form and optical orientation, but *n* decreases, whilst the double refraction increases ( $\gamma$ -form). This is transformed at  $180^\circ$  into the  $\beta$ -form (*n*  $<$  that of natural anhydrite). At  $520^\circ$  the  $\beta$ -form gives the  $\alpha$ -form. H. J. E.

**Zinc, even impure but perfectly smooth and without external contamination, does not effervesce with dilute acids.** P. RONCERAY (Bull. Soc. chim., 1936, [v], 3, 206—213).—The technique described for Fe (A., 1935, 834; this vol., 174) has been applied to Zn with similar results. E. S. H.

**Barium arsenates. Characterisation of  $2\text{As}_2\text{O}_5 \cdot 3\text{BaO}$ .** H. GUÉRIN (Compt. rend., 1936, 202, 225—227; cf. this vol., 173).—The thermal decomp. of Ba meta-, ortho-, and pyroarsenates has been investigated.  $\text{BaO} \cdot \text{As}_2\text{O}_5$  when heated in a vac. at  $700^\circ$  yields the sesquiarsenate  $3\text{BaO} \cdot 2\text{As}_2\text{O}_5$ .

T. G. P.

**Purification of mercury.** B. PESCE (Annali Chim. Appl., 1935, 25, 654—657).—A pycnometer for determining the  $d$  of Hg is described. The presence of very small amounts of impurities in Hg can be detected most readily by  $d$  determinations. Hg cannot be purified completely by distillation only, but two preliminary distillations followed by the treatment suggested by Beutell (A., 1910, ii, 105) give a pure product.

A. M. P.

**Reactions of mercuric oxide.** E. MONTIGNIE (Bull. Soc. chim., 1936, [v], 3, 459—460).—The reactions of HgO with KCN, KCNS,  $\text{K}_4\text{Fe}(\text{CN})_6$ ,  $\text{K}_2\text{Fe}(\text{CN})_6$ ,  $\text{NaBO}_2$ , Te, P, As, and Sb are described.

E. S. H.

**Action of mercuric oxide on solutions of sulphates and nitrates.** E. MONTIGNIE (Bull. Soc. chim., 1936, [v], 3, 193—196).—The products of reaction with Al,  $\text{Ti}^{IV}$ ,  $\text{Ce}^{III}$ ,  $\text{Fe}^{II}$ ,  $\text{Mn}^{II}$ , Zn, and  $\text{Cu}^{II}$  sulphates, and Bi, Zr,  $\text{Cu}^{II}$ , and  $\text{Ni}^{II}$  nitrates have been identified. HgO does not react with aq.  $\text{AgNO}_3$  or  $\text{UO}_2(\text{NO}_3)_2$ .

E. S. H.

**Mercuric chromates.** E. MONTIGNIE (Bull. Soc. chim., 1936, [v], 3, 460—462).—The conditions of formation of  $\text{HgCrO}_4$  and  $\text{HgSO}_4$  in the systems (1)  $\text{Hg}-\text{H}_2\text{SO}_4-\text{K}_2\text{CrO}_4$ , (2)  $\text{HgO}-\text{H}_2\text{SO}_4-\text{K}_2\text{CrO}_4$ , (3)  $\text{Hg}-\text{H}_2\text{SO}_4-\text{CrO}_3$ , (4)  $\text{HgO}-\text{H}_2\text{SO}_4-\text{CrO}_3$  at  $10-15^\circ$  have been determined.

E. S. H.

**Action of mercuric oxide on potassium dichromate.** E. MONTIGNIE (Bull. Soc. chim., 1936, [v], 3, 419—420).—With small amounts of HgO, the product is  $\text{HgCrO}_4$ ; further addition of HgO produces basic chromates.

E. S. H.

**Aluminium, even impure but perfectly smooth and without external contamination, does not effervesce with dilute acids.** P. RONCERAY (Bull. Soc. chim., 1936, [v], 3, 213—218).—The results obtained with Zn (see above) have also been observed with Al.

E. S. H.

**Decomposition of sodium aluminates.** V. D. DJATSCHKOV and O. S. KOSHUCHOVA (Kolloid-Z., 1936, 74, 196—200).—The stability of solutions of Na aluminate increases rapidly with increase of the ratio  $\text{Na}_2\text{O}/\text{Al}_2\text{O}_3$  above 1.4—1.5. The solutions exhibit min. stability at a concn. of 120—180 g.  $\text{Al}_2\text{O}_3$  per litre. Addition of  $\text{Na}_2\text{SiO}_3$  first stabilises the solutions, but at higher concns. causes coagulation, the pptd.  $\text{Al}_2\text{O}_3$  being contaminated with  $\text{SiO}_2$ . Addition of agar-agar increases the stability, whilst gelatin, methylene-blue, and Me-violet have no effect, and tannic acid very little.

F. L. U.

**Acid fluorides of univalent cations.** C. FINBAK and O. HASSEL (Z. anorg. Chem., 1936, 226, 175—176).—Determination of the lattice consts. of the TI compound, obtained by the concn. of the solution of  $\text{Ti}_2\text{O}$  or  $\text{Ti}_2\text{CO}_3$  in excess of HF, indicates that it is a silicofluoride and not an acid fluoride as supposed by other investigators. Similar conclusions have been reached previously with regard to other so-called "acid fluorides," and doubt is thrown on the possibility of the existence of acid fluorides in general.

M. S. B.

**Reactivity of red and yellow lead oxide with silica.** J. A. HEDVALL and A. ELDH (Z. anorg. Chem., 1936, 226, 192—196).—The amount of reaction occurring between red PbO and  $\text{SiO}_2$ , when an intimate mixture of the two is heated for 1 hr. at  $450-650^\circ$ , has been determined and compared with the rate of transition from red to yellow PbO at the same temp. Although the transition temp. is  $488.5^\circ$  both the rate of reaction with  $\text{SiO}_2$  and the rate of transition begin to be appreciable at approx.  $600^\circ$  only. Above this temp. both increase rapidly. The temp.-reactivity curve for red PbO with  $\text{SiO}_2$  is practically identical with that for yellow PbO, since the slight pressure used in mixing results in partial transformation into the stable red form.

M. S. B.

**Induced oxidation of nitrogen.** M. POLJAKOV (Compt. rend. Acad. Sci. U.R.S.S., 1935, 4, 35—36).—A discussion of the formation of N oxides in gaseous explosions.

H. J. E.

**Structure of nitrogen peroxide deduced from its action on potassium iodide.** M. DODÉ (Compt. rend., 1935, 201, 1378—1380).—The reactions between  $\text{N}_2\text{O}_4$  and KI or aq. KI have been investigated; they indicate that  $\text{N}_2\text{O}_4$  exists in at least two forms in equilibrium.

T. G. P.

**Non-existence of the nitrosyl of Angeli.**—See this vol., 460.

**Nitrogen iodide.** E. ROEDERER (Z. anorg. Chem., 1936, 226, 145—167).—Attempts to employ  $\text{N}_2\text{H}_3\text{I}_3$  for the development of a new photographic process, depending on photochemical reactions with the highest possible quantum output, were unsuccessful.  $\text{N}_2\text{H}_3\text{I}_3$  shows a max. stability in aq. solution at  $p_H$  approx. 10. The requisite  $p_H$  is a little higher in the presence of aq.  $\text{NH}_3$  than in its absence. The equilibrium const. for the formation of  $\text{N}_2\text{H}_3\text{I}_3$  from aq.  $\text{NH}_3$  and I in aq. solution is  $K = [\text{NH}_4]^2[\text{OH}]^5[\text{I}]^3/[\text{I}']^3$  and is approx.  $10^{-29.23}$ . No  $\text{N}_2\text{H}_3\text{I}_3$  is formed by the interaction of  $\text{NH}_3$  and I in  $\text{CCl}_4$ . An additive product is mainly obtained, as in the reaction between gaseous  $\text{NH}_3$  and solid I, but there is also a small amount of oxidation of  $\text{NH}_3$ , probably to  $\text{N}_2$  and  $\text{H}_2$ , and simultaneous reduction of I to I' with formation of  $\text{NH}_4\text{I}$ . Similar behaviour is observed in  $\text{C}_6\text{H}_6$  solution. A reaction scheme is suggested. The distribution coeff. of  $\text{NH}_3$  between  $\text{CCl}_4$  and the gas phase is  $7.24 \pm 0.04$ .

M. S. B.

**Decomposition of nitrogen iodide.** W. E. GARNER and W. E. LACHEM (Trans. Faraday Soc., 1936, 32, 567—569).—See A., 1935, 828.

F. L. U.

**Constitution and mechanism of formation of the solid, yellow hydride of phosphorus.** P. ROYEN and K. HILL (*Naturwiss.*, 1936, 24, 108).—The hydride of P, generally regarded as  $P_{12}H_6$ , is not a definite compound, but arises from adsorption of  $PH_3$  on an amorphous, yellow P. X-Ray diagrams of  $P_{12}H_6$  and  $P_9H_2$  show no interference. More difficultly volatile mols., e.g.,  $NH_3$ , piperidine, and  $PEt_3$ , can cause partial or complete removal of the hydride as  $PH_3$ . The formation of red alkali-metal salts in aq.-EtOH solutions is probably due to peptisation, rather than to the existence of an acidic H in  $P_{12}H_6$ . The formula of the hydride is dependent on surface conditions, and varies from  $P_{12}H_{5.8}$  to  $P_{12}H_{7.2}$ . It is suggested that the reaction is  $3P_2H_4 = 4PH_3 + 2P$ , analogous to the reaction between  $PH_3$  and  $PEt_2Cl$ , in which an unstable intermediate compound,  $PH_2PEt_2$  is formed, and decomposes to give amorphous yellow P and  $PH_2Et$ ,  $PHEt_2$ , and  $PEt_3$ , some of these being adsorbed on the P. A. J. M.

**Phosphorus pernitride  $P_4N_6$ .** H. MOUREU and G. WETROFF (*Compt. rend.*, 1935, 201, 1381—1383).—The products of the reaction of  $PCl_3$  on liquid  $NH_3$ , heated in a vac. at  $550^\circ$ , yield  $P_4N_6$ , a white, insol., non-volatile substance spontaneously inflammable in air, and hydrolysed at  $215^\circ$  thus:  $P_4N_6 + 15H_2O = 2(NH_4)_2HPO_4 + NH_4H_2PO_4 + NH_4H_2PO_3$ . Under similar conditions  $P_3N_5 + 12H_2O = 2(NH_4)_2HPO_4 + NH_4H_2PO_4$ .  $P_4N_6$  heated above  $750^\circ$  in a vac. gives PN, which condenses out in a pure state. PN is completely hydrolysed only after 3 days at  $215^\circ$ . The primary reaction is  $PN + 3H_2O = NH_4H_2PO_3$ . T. G. P.

**Action of arsenic trichloride on the elements.** E. MONTIGNIE (*Bull. Soc. chim.*, 1936, [v], 3, 190—191).—At room temp. S, Bi, and Al are unattacked; with Se, Te, Pb, and Au, respectively, As is liberated and  $Se_2Cl_2$ ,  $TeCl_4$ ,  $PbCl_2$ , and  $AuCl_3$  formed; Ag forms  $AsCl_3Ag_3$ . E. S. H.

**Formulae of basic salts of bismuth.** M. PICON (*Bull. Soc. chim.*, 1936, [v], 3, 186—190).—The system advocated shows the ratio of acid radicals to metal atoms: e.g.,  $Bi_{20}O_{21}(NO_3)_{18} \cdot 6H_2O$  instead of  $10Bi_2O_3 \cdot 9N_2O_5 \cdot 6H_2O$ . E. S. H.

**Bivalent bismuth iodide.** E. MONTIGNIE (*Bull. Soc. chim.*, 1936, [v], 3, 191—193).—Unsuccessful attempts to prepare  $BiI_2$  are recorded. E. S. H.

**Preparation of bismuth iodosulphide by the wet method.** F. FRANÇOIS and M. L. DELWAULLE (*Bull. Soc. chim.*, 1936, [v], 3, 504—508).— $BiSI$  is formed by the action of  $H_2S$  or  $Bi_2S_3$  on solutions of  $BiI_3$  in HI, or by the action of HI on  $Bi_2S_3$ . Determinations of Bi as  $Bi_2S_3$  in solutions containing I are rendered invalid by pptn. of  $BiSI$ . E. S. H.

**Basic organic salts of bismuth.**—See this vol., 460.

**Occlusion of protoactinium by sulphides insoluble in hydrochloric acid.** CHENG DA-CHANG and L. HOANG (*Bull. Soc. chim.*, 1936, [v], 3, 326—328).—The co-pptn. of Pa with  $CuS$ ,  $Sb_2S_3$ ,  $HgS$ , and  $Bi_2S_3$  has been studied under different conditions of concn. and acidity. Pa sulphide is sol. in the aq. HCl, but is adsorbed incompletely by the ppt. E. S. H.

**Oxidation of inorganic reagents by ozone. I. Potassium iodide.** G. GUÉRON, M. PRETTE, and J. GUÉRON (*Bull. Soc. chim.*, 1936, [v], 3, 295—312).—Experiments in buffered, neutral solutions show that the normal reaction  $2I' + O_3 + H_2O = I_2 + O_2 + 2OH'$  is accompanied by an independent, heterogeneous reaction,  $I' + 3O_3 = IO_3' + 3O_2$ . The latter reaction preponderates in presence of a large glass surface. The influence of concn. has been studied. Preliminary observations have been made on the simultaneous oxidation of  $AsO_3'''$ . E. S. H.

**Constitution of sulphato-compounds.** A. VON KISS (*Z. anorg. Chem.*, 1936, 226, 141—144).—The dialysis method is not a conclusive test for the existence of true complex compounds, since a simple association of ions without change of the constitution of the co-ordination zone will produce the effect of increased ionic wt. The method must be combined with spectroscopic determinations. These do not confirm the formation of true complex sulphates reported by Brintzinger *et al.* (A., 1935, 181). M. S. B.

**Transformation from vitreous to metallic selenium.** K. TANAKA and H. Y. TIEN (*Mem. Coll. Sci. Kyoto*, 1935, A, 18, 309—310; cf. A., 1935, 920).—Between  $65^\circ$  and  $80^\circ$ , the wt.-% of metallic Se,  $p$ , in the specimen annealed for  $t$  hr. is  $p = P(1 - e^{-ct - t'})$ , where  $P$  is approx. 78.5%,  $t'$  decreases from 4 to 0.65 and  $c$  increases from 0.062 to 1.11 as the temp. is raised. J. G. A. G.

**Purification and preparation of very intense polonium sources.** M. HAISSINSKY (*J. Chim. phys.*, 1936, 33, 97—98).—Po can be separated from Te, Au, Hg, and Pt by reducing the latter with  $N_2H_4$ . Pptn. is preferably carried out in solution sufficiently acid to prevent adsorption of Po by the pptd. metal (20% HCl or AcOH). The Po can then be deposited by introduction of a polished Ag disc. J. W. S.

**Preparation of polonium sources from radon bulbs.** L. R. HAFSTAD (*J. Franklin Inst.*, 1936, 221, 191—213).—Details of the prep. of strong Po sources by an elaboration of the Curie method (A., 1926, 5) are given. R. S.

**Preparation of chemically pure hydrochloric acid.**—See B., 1936, 190.

**Existence of chlorous anhydride  $[Cl_2O_3]$ .** M. KANTZER (*Compt. rend.*, 1936, 202, 209—210).—The action of conc.  $H_2SO_4$  on  $KClO_3$  at  $-15^\circ$  in presence of undecenoic acid yields  $ClO_2$  and  $Cl_2O_3$ . The absorption spectrum of  $ClO_2$  consists of three groups of bands between 3895 and 4180 Å.  $Cl_2O_3$  absorbs continuously between 3500 and 4260 Å., and has 10 broad bands between 4260 and 4649 Å. T. G. P.

**Mechanism of permanganate reduction and the induced oxidation of chlorion.** H. BASSETT and I. SANDERSON (*J.C.S.*, 1936, 207—211).— $Mn'''$  is the first identifiable product when  $MnO_4'$  is reduced by  $Fe''$ . Induced oxidation of  $Cl'$  in permanganate reactions is attributed to  $Mn'''$  and especially  $Mn''$ , because the process  $Mn''' \rightarrow Mn''$  is probably simpler than  $MnO_4' \rightarrow Mn'''$ . The end-point of the titration  $FeCl_2-KMnO_4$  is most nearly stoichiometric when

Mn<sup>++</sup> or substances forming stable complexes with Mn<sup>+++</sup>, e.g., SO<sub>4</sub><sup>''</sup>, PO<sub>4</sub><sup>'''</sup>, F', and Cl', are added. Solutions 2–3*N* with respect to H<sub>2</sub>SO<sub>4</sub> are best (cf. this vol., 44) but the end-point is always unstable, possibly owing to the change 2Mn<sup>+++</sup> = Mn<sup>++</sup> + Mn<sup>++++</sup>. PO<sub>4</sub><sup>'''</sup> is almost completely pptd. as the Mn<sup>++</sup> salts of complex Mn<sup>IV</sup> phosphoric acids by digesting with conc. HNO<sub>3</sub> and Mn or Mn<sup>++</sup>. J. G. A. G.

Induced oxidation of potassium iodide by ozone. (MME.) G. GUÉRON, J. GUÉRON, and M. PRETTE (Compt. rend., 1935, 201, 1376–1378; cf. A., 1935, 945).—The heterogeneous oxidation of KI by O<sub>3</sub> in aq. solution is not an induced oxidation. With greatly diluted O<sub>3</sub> an induced oxidation accompanies, to a slight extent, the normal reaction O<sub>3</sub> + 2I' + H<sub>2</sub>O = O<sub>2</sub> + I<sub>2</sub> + 2OH'. T. G. P.

Iron of high purity. F. ADCOCK and C. A. BRISTOW (Proc. Roy. Soc., 1935, A, 153, 172–200).—Fe has been prepared (1) by the electrolysis of a solution of FeCl<sub>2</sub> and NaCl, using an "Arceo" Fe anode, and (2) by the decomp. of FeCl<sub>2</sub> by steam, in each case followed by treatment of the molten metal with a stream of pure H<sub>2</sub> and subsequent melting in vac. The work was controlled by chemical and X-ray analysis. Measurable differences existed in the physical properties of different batches. The α-γ transformation in some of the samples, indicated by dilatometric observations, does not take place at a const. temp. but over a definite temp. range. L. L. B.

Polished iron, even impure, does not oxidise in saturated moist air. P. RONCERAY (Bull. Soc. chim., 1936, [v], 3, 320–321).—A reply to criticism (cf. this vol., 174). E. S. H.

Active oxides. XCIII. Intermediate active states in the decomposition of needle iron ore into α-iron oxide and water vapour. G. F. HÜTTIG and E. STROTZER [with O. HNEVKOVSKY and H. KITTEL]. XCVII. A crystallised basic aluminium sulphite, Al<sub>2</sub>O<sub>3</sub>·2SO<sub>2</sub>·H<sub>2</sub>O. E. ROSENKRANZ and G. F. HÜTTIG (Z. anorg. Chem., 1936, 226, 97–125, 126–131).—XCIII. The changes in colour, bulk *d*, magnetic susceptibility, "apparent" mol. vol., and crystal structure, taking place during the dehydration of artificially prepared needle Fe ore, α-Fe<sub>2</sub>O<sub>3</sub>·H<sub>2</sub>O, have been followed, and the results are discussed. There are no sharply defined intermediate active states, but the property-composition curves show points of inflexion.

XCVII. A basic compound, Al<sub>2</sub>O<sub>3</sub>·2SO<sub>2</sub>·H<sub>2</sub>O, has been separated from an aq. solution of Al<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub> by shaking at 78–80° until some of the SO<sub>2</sub> was driven off. The composition of the salt was confirmed by the isobaric decomp. curve and X-ray examination. M. S. B.

Ferric ammonium carbonate. V. AUGER and (MLLE.) M. GALLISSOT (Compt. rend., 1936, 202, 224–225).—Aq. FeCl<sub>3</sub> reacts with a large excess of saturated aq. NH<sub>4</sub>HCO<sub>3</sub> in presence of undissolved NH<sub>4</sub>HCO<sub>3</sub> and CO<sub>2</sub> to yield unstable yellow prisms, [Fe(OH)<sub>2</sub>NH<sub>3</sub>(H<sub>2</sub>O)]HCO<sub>3</sub>. T. G. P.

Two double salts of ferric fluoride. A. H. NIELSEN (Z. anorg. Chem., 1936, 226, 222–224).—

The salts Sr<sub>3</sub>Fe<sub>2</sub>F<sub>12</sub>·2H<sub>2</sub>O, *d* 3.71, and BaFeF<sub>5</sub>·H<sub>2</sub>O, *d* 3.94, have been prepared and their chemical and crystallographic properties determined. M. S. B.

Complex chemical behaviour of *o*-amino-phenol.—See this vol., 465.

Complex salts of α-phenylethylamine. Equivalence of the four co-valencies of bivalent platinum and palladium.—See this vol., 462.

Duration of analyses. RAUCH (Document. sci., 1935, 4, 4–10; Chem. Zentr., 1935, i, 3818).—The time taken for completion of various routine analyses has been determined. J. S. A.

Quantitative spectrum analysis. I, II. W. VAN TONGEREN (Chem. Weekblad, 1936, 33, 130–141, 151–159).—A historical review, with full experimental details of published methods. D. R. D.

Chromatographic analysis and its applications. H. WILLSTAEDT (Svensk Kem. Tidskr., 1936, 48, 32–48).—A lecture.

Adsorption analysis of aqueous solutions. W. KOSCHARA (Z. physiol. Chem., 1936, 239, 89–96).—The differences involved in the application of adsorption analyses in aq. and org. media are discussed. The use of natural or acid-treated fuller's earth, Brockmann's Al<sub>2</sub>O<sub>3</sub>, and Al<sub>2</sub>O<sub>3</sub>·H<sub>2</sub>O and the dependence of efficiency on the *p*<sub>H</sub> of the solution are considered. H. W.

Influence of temperature on *p*<sub>H</sub> measurements in alkaline media. P. SZIGETI (Nature, 1936, 137, 276).—Alkaline *p*<sub>H</sub> vals. are valueless unless temp. is also recorded. L. S. T.

Analysis with fluorescent indicators. M. DÉRI-BÉRÉ (Ann. Chim. Analyt., 1936, [iii], 18, 37–39).—Acid-alkali titrations are performed in ultra-violet light, using the change of fluorescence colour at some characteristic *p*<sub>H</sub> to mark the end-point. Umbelliferone, β-methylumbelliferone, and uranyl salts (in the absence of halogens) are suitable for strong acid-strong base titrations; β-C<sub>10</sub>H<sub>7</sub>·OH or eosin BN for weak acids; and aesculin or fluorescein for weak bases. J. S. A.

Use of the micro-thermal conductivity method for the determination of heavy hydrogen. A. FARKAS, L. FARKAS, and E. K. RIDEAL (Nature, 1936, 137, 315).—The reliability and accuracy of the method is maintained (cf. this vol., 181). L. S. T.

Determination of bound water by means of the ultracentrifuge. J. W. McBAIN (J. Amer. Chem. Soc., 1936, 58, 315–317).—Theoretical. Formulae are derived to show the error caused by neglecting solvation in ultracentrifuge determinations. E. S. H.

Analysis of heavy water. A. FARKAS (Trans. Faraday Soc., 1936, 32, 413–415).—The micro-thermo-conductivity method for the analysis of H<sub>2</sub>-D<sub>2</sub> mixtures is applied to the analysis of H<sub>2</sub>O-D<sub>2</sub>O mixtures. The D content of the latter is calc. from the observed D<sub>2</sub> content of H<sub>2</sub>-D<sub>2</sub> gas brought into equilibrium with the water. The method is specially suitable for investigating the interchange of H and D atoms between water and other substances.

without the need of separating the water for each determination. O. J. W.

**Colour reactions of the chlorate ion.** A. SÁ (An. Farm. Bioquim., 1934, 5, 111—114; Chem. Zentr., 1935, i, 3573).—The same colours are given by  $\text{ClO}_3'$ ,  $\text{NO}_3'$ , and  $\text{NO}_3'$  with  $\text{NHPh}\cdot\text{C}_{10}\text{H}_7\text{-}\alpha$  and with  $\text{NH}(\text{C}_{10}\text{H}_7\text{-}\alpha)_2$ . Different colours (described) are given with  $\text{NHPh}\cdot\text{C}_{10}\text{H}_7\text{-}\beta$ ,  $\text{NH}(\text{C}_{10}\text{H}_7\text{-}\beta)_2$ , and phenyl-dihydrodibenzacridine. H. N. R.

**Determination of iodine in iodised salt.**—See B., 1936, 232.

**Determination of oxygen dissolved in 1 c.c. of water.**—See B., 1936, 254.

**Polarographic studies with the dropping mercury cathode. LVII. Determination of oxygen in gases and solutions.** V. VÍTEK (Coll. Czech. Chem. Comm., 1935, 7, 537—547).—The electroreduction of  $\text{O}_2$  causes two "waves" in the current-voltage curve corresponding with reduction first to  $\text{H}_2\text{O}_2$  and then to  $\text{H}_2\text{O}$ , and the magnitude of the saturation current of the total reduction of  $\text{O}_2 \propto [\text{O}_2]$  and permits  $[\text{O}_2]$  as low as 0.04 mg. per litre to be determined in a fraction of 1 c.c. 0.05—100% of  $\text{O}_2$  in gaseous mixtures is determined within  $\pm 2\%$  of the total  $[\text{O}_2]$  by bubbling through MeOH and determining the solubility of the  $\text{O}_2$  polarographically. J. G. A. G.

**Determination of sulphur in silicates.** A. F. FIOLETOVA (J. Appl. Chem. Russ., 1935, 8, 1461—1464).—Total S is best determined as  $\text{SO}_4''$  after fusion with  $\text{Na}_2\text{CO}_3\text{--KNO}_3$ .  $\text{SO}_4''$  is determined by extraction for 1 hr. with boiling 10% HCl in an inert atm.; atm.  $\text{O}_2$  leads to high vals., owing to oxidation of sulphide S to  $\text{SO}_4''$ . No satisfactory direct method of determination of sulphide S was found. R. T.

**Indirect colorimetric semi-micro-determination of the sulphate anion.** F. A. GOIN (An. Farm. Bioquim., 1934, 5, 61—68; Chem. Zentr., 1935, i, 3573).—The colour reaction between benzidine and  $\text{AcOH}\text{--NaNO}_2$  in EtOH is applied to the determination of  $\text{SO}_4''$  in urine. H. N. R.

**Determination of sulphate.** Conditions necessary for the precipitation of benzidine sulphate, with special reference to the determination of sulphates in urine. E. C. OWEN (Biochem. J., 1936, 30, 352—360).—The pptn. of  $\text{SO}_4''$  by benzidine (I) is optimal at  $p_H$  2—3;  $\text{HPO}_4''$  is pptd. by (I) at  $p_H > 2$  and may be removed before the  $\text{SO}_4''$  determination by the method of Fiske (A., 1921, ii, 556). The  $[\text{Cl}']$  in the urine is not sufficient to produce appreciable errors. H. D.

**Application of the systems water-ethyl alcohol-potassium carbonate and -ammonium sulphate to the rapid detection of certain anions.** A. G. KOBLJANSKI (J. Appl. Chem. Russ., 1935, 8, 1494—1497).—In the two-phase liquid system EtOH-saturated aq.  $\text{K}_2\text{CO}_3$ , the anions  $\text{SO}_4''$ ,  $\text{Cl}'$ ,  $\text{Fe}(\text{CN})_6'''$ , and  $\text{Fe}(\text{CN})_6'''$  are present chiefly in the aq. and  $\text{I}'$ ,  $\text{CNS}'$ , and  $\text{S}''$  in the EtOH, layer, whilst in EtOH-saturated aq.  $(\text{NH}_4)_2\text{SO}_4$   $\text{I}'$ ,  $\text{Br}'$ ,  $\text{Cl}'$ ,  $\text{CNS}'$ ,  $\text{Fe}(\text{CN})_6'''$  and  $\text{Fe}(\text{CN})_5\text{NO}''$  are found chiefly in the EtOH, and

$\text{Fe}(\text{CN})_6'''$  in the aq. layer. These findings are applied to the detection of the individual anions when present together. R. T.

**Gravimetric determination of selenates.** P. SPACU (Bull. Soc. chim., 1936, [v], 3, 159).—The slightly acid  $\text{SeO}_4''$  solution is treated with aq.  $\text{Pb}(\text{OAc})_2$  and the mixture boiled. The ppt. is collected, dried in vac., and weighed as  $\text{PbSeO}_4$ . E. S. H.

**Colorimetric determination of nitrates in water: influence of chlorides.**—See B., 1936, 254.

**Differentiation of constituents of nitrous vapours by formation of nitrogen compounds.** A. SANFOURCHE and J. BUREAU (Compt. rend., 1936, 202, 66—69).—Tests are described in which various mixtures of NO and  $\text{NO}_2$  were analysed (a) by absorption in  $\text{H}_2\text{SO}_4$  ( $d$  1.833), and (b) by absorption in a solution of  $\text{NH}_2\text{Ph}\cdot\text{HCl}$ . The latter method gave more trustworthy analytical results. H. J. E.

**Determination of nitrate- and nitrite-nitrogen with copper-zinc powder.** T. ARND and H. SEEBERG (Angew. Chem., 1936, 49, 166—167).—The vals. formerly obtained (B., 1932, 201; 1933, 118) were due mainly to the method of prep. of the Cu-Zn powder. Directions are given for this prep. and the method is recommended for fertilisers etc. D. C. J.

**Potentiometric titration of phosphates.** E. MICHALSKI (Rocz. Chem., 1935, 15, 468—480).—Excess of standard  $\text{AgNO}_3$  is added to the alkaline solution, 0.1N-NaOH is added to neutrality (orange coloration with phenol-red), a drop of  $N\text{-AcOH}$  is added, and Ag is determined in the filtrate; the results are 0.2% > the theoretical, owing to adsorption of Ag by the ppt. of  $\text{Ag}_3\text{PO}_4$ . Ca, Sr, Ba, and Mg do not interfere, but Cl, Br, I,  $\text{NH}_4$ , Al, and Fe should be absent. R. T.

**Sensitive reaction for phosphate.** A. STEIGMANN (Chem.-Ztg., 1936, 60, 129).—The sensitivity of the phosphomolybdate reaction is enhanced by adding a glycerol-gelatin solution, which is boiled until the protein no longer gives turbidity with  $(\text{NH}_4)_2\text{MoO}_4$ . J. S. A.

**Fluorine and ammonia as sources of error in determination of phosphate by the [hydroxy]-apatite method.** A. T. JENSEN (K. Veterin. Landsb. Aarskr., 1935, 41—50; Chem. Zentr., 1935, ii, 255).—Modifications of Damsgaard and Sørensen's method are described, eliminating errors due to the presence of  $\text{F}'$  or  $\text{NH}_3$  (cf. A., 1935, 718). J. S. A.

**Separate determination of arsine and phosphine in air.** V. G. GUREVITSCH and B. A. RASCHKOVAN (J. Gen. Chem. Russ., 1935, 5, 1317—1323).—1 c.c. of 12% KBr is added to the solution, containing 0.2 mg. of  $\text{H}_3\text{PO}_4$  and  $\text{H}_3\text{AsO}_4$ , the mixture is evaporated to dryness, 5 c.c. of 1—7N-HCl are added, and the solution is again evaporated to dryness (twice), the residue is dissolved in  $\text{H}_2\text{O}$ , and  $\text{H}_3\text{PO}_4$  is determined colorimetrically.  $\text{H}_3\text{AsO}_4$  is determined in presence of  $\text{H}_3\text{PO}_4$  by reducing with nascent H to  $\text{AsH}_3$  (0.001—0.05 mg.), absorbing the gaseous products in conc.  $\text{HNO}_3$ , evaporating the  $\text{HNO}_3$  to dryness, and determining  $\text{H}_3\text{AsO}_4$  in the residue by the

ordinary colorimetric procedure.  $\text{AsH}_3$  and  $\text{PH}_3$  in air are determined by absorption in conc.  $\text{HNO}_3$ , evaporation, and analysis of the residue by the above methods.

R. T.

**Risk of error in determining traces of arsenic in organic and inorganic materials.** W. A. DAVIS and J. G. MALBY (Analyst, 1936, 61, 96—100).—Before applying the Marsh or Gutzeit test  $\text{AsO}_4^{3-}$  must be reduced to  $\text{AsO}_3^{3-}$ , preferably by warming with aq.  $\text{H}_2\text{SO}_3$  or  $\text{NaHSO}_3$ , excess of which must be removed. During the actual test the Gutzeit flask should be heated at 40—60°.

E. C. S.

**Colorimetric determination of small quantities of silica in solutions, minerals, and technical products.** I. P. ALIMARIN and V. S. ZVEREV (Trans. Inst. Econ. Min. U.S.S.R., 1934, No. 63, 15 pp.).—A crit. survey. Dienert and Wandenbulcke's method, based on the formation of  $\text{H}_8[\text{Si}(\text{Mo}_2\text{O}_7)_6]$ , is best for 0.005—5%  $\text{SiO}_2$ . In presence of large amounts of mineral acids and their hydrolysable salts,  $\text{NaOAc}$  should be added. The effects of P and Fe are counteracted by adding excess of  $\text{H}_3\text{PO}_4$ . The phosphomolybdate colour can also be removed with tartaric or citric acid. The effect of F is avoided by adding  $\text{AlCl}_3$ , which forms  $\text{H}_3\text{AlF}_6$  from  $\text{H}_2\text{SiF}_6$ .

CH. ABS. (e)

**Rapid gravimetric determination of silicic acid.**—See B., 1936, 190.

**Quantitative spectrography of alkali metals.** P. URBAIN and M. WADA (Bull. Soc. chim., 1936, [7], 3, 163—169).—An electric arc between Cu electrodes is used. To reduce the rate of vaporisation of the alkali-metal compound, it is mixed with a refractory substance. Determination is by comparison of line intensities.

E. S. H.

**Determination of sodium chloride in salt.**—See B., 1936, 232.

**Reaction for calcium.** S. A. CELSI (An. Farm. Bioquim., 1934, 5, 85—89; Chem. Zentr., 1935, i, 3573).—A mixture of  $\text{K}_4\text{Fe}(\text{CN})_6$  and  $\text{Cu}(\text{NH}_4)_2\text{SO}_4 \cdot \text{H}_2\text{O}$  gives with  $\text{Ca}^{++}$  a sky-blue ppt.

H. N. R.

**Application of copper ferrocyanide ammoniate in testing for calcium.** J. V. DUBSKÝ and A. LANGER (Coll. Czech. Chem. Comm., 1936, 8, 47—56).—By the action of  $\text{K}_4\text{Fe}(\text{CN})_6$  on solutions of  $\text{CaCl}_2 + \text{CuCl}_2$  in presence of  $\text{NH}_3$ ,  $(\text{CH}_2\text{NH}_2)_2$  (en), or  $\text{C}_2\text{H}_5\text{N}$ , the following compounds have been obtained:  $\text{Cu}_2\text{Ca}(\text{NH}_4)_2[\text{Fe}(\text{CN})_6]_2 \cdot 8\text{NH}_3 \cdot 6\text{H}_2\text{O}$ ;  $\text{Cu}_2\text{Ca}(\text{NH}_4)_2[\text{Fe}(\text{CN})_6]_2 \cdot 6\text{H}_2\text{O}$ ;  $\text{CuCa}[\text{Fe}(\text{CN})_6]_2 \cdot 5$ , and  $6\text{NH}_3 \cdot 2\text{H}_2\text{O}$ ;  $\text{CuCa}[\text{Fe}(\text{CN})_6] \cdot 6\text{NH}_3 \cdot 3\text{H}_2\text{O}$ ;  $\text{Cu}_2[\text{Fe}(\text{CN})_6] \cdot \text{en}_3 \cdot 6\text{H}_2\text{O}$ ;  $\text{CuCa}[\text{Fe}(\text{CN})_6] \cdot \text{en}_2 \cdot 2\text{H}_2\text{O}$ ;  $\text{Cu}_2[\text{Fe}(\text{CN})_6] \cdot 4\text{C}_2\text{H}_5\text{N} \cdot 6\text{H}_2\text{O}$ ;  $\text{Cu}_2\text{Ca}[\text{Fe}(\text{CN})_6]_2 \cdot 8\text{C}_2\text{H}_5\text{N} \cdot 30\text{H}_2\text{O}$ . Speculative coordination formulæ are advanced.

J. S. A.

**Potentiometric determination of calcium concentrations in solutions.** H. J. C. TENDELOO (J. Biol. Chem., 1936, 113, 333—339).—A method, using a  $\text{CaF}_2$  electrode, is described. Absorption of Ca by proteins decreases with increasing acidity.

H. G. R.

**Determination of radium in carnotite and pitchblende.**—See B., 1936, 232.

**Dithizone method for determination of lead.** P. A. CLIFFORD and H. J. WICHMANN (J. Assoc. Off. Agric. Chem., 1936, 19, 130—156).—The transmission spectra of solutions of dithizone (I) in  $\text{CHCl}_3$  and  $\text{CCl}_4$  show strong absorption at 600  $\text{m}\mu$ , and a weak band at 450  $\text{m}\mu$ . The quant. relation between Pb and (I) at  $p_{\text{H}}$  vals. between 5 and 12, and the principles and inherent errors of the different methods of extraction and colorimetric determination, are discussed. Procedures, based on the "mixed-colour" method (cf. B., 1934, 379) with the use of a photometer, are outlined for the determination of Pb in urine and bone etc.

E. C. S.

**Volumetric determination of lead and of molybdates with adsorption indicators.** C. CANDEA and I. G. MURGULESCU (Ann. Chim. Analyt., 1936, [iii], 18, 33—36).—Pb, present as  $\text{Pb}(\text{OAc})_2$  or  $\text{Pb}(\text{NO}_3)_2$ , is titrated against  $\text{MoO}_4^{2-}$  using eosin A as adsorption indicator.

J. S. A.

**Gravimetric determination of lead as lead chromate.** L. GUZELJ (Z. anal. Chem., 1936, 104, 107—119).—The accuracy of the method is not affected by the presence of  $\text{AcOH}$ ,  $\text{NH}_4\text{OAc}$ ,  $\text{KCl}$ ,  $\text{KBr}$ ,  $(\text{NH}_4)_2\text{SO}_4$ , or  $\text{NH}_4\text{NO}_3$ , but  $[\text{HNO}_3]$  should be  $> 0.1N$ . Addition of  $\text{NH}_3$  after pptn. may lead to the formation of basic Pb chromate, which is hindered by  $\text{NH}_4\text{OAc}$  or  $(\text{NH}_4)_2\text{CrO}_4$ .  $[\text{Pb}]$  should be as low as is practicable.

J. S. A.

**Determination of lead and antimony in pure metals and their alloys.** H. VDOVISZEWSKI (Z. anal. Chem., 1936, 104, 94—107).—The determination of Pb as  $\text{PbSO}_4$  by Treadwell's method, and of Sb as  $\text{Sb}_2\text{S}_3$  by Vortmann and Metzl's method, is critically reviewed, and modifications of procedure are advocated. The determination of Pb as  $\text{PbCrO}_4$  is rapid, but leads to slightly high results.

J. S. A.

**Gravimetric determination of certain metals [with thiolbenzthiazole].** III. Determination of lead, thallium, bismuth, and gold. G. SPACU and M. KURAS (Z. anal. Chem., 1936, 104, 88—93).—Pb is pptd. quantitatively by thiolbenzthiazole (I) from hot ammoniacal solutions as the basic salt,  $\text{C}_7\text{H}_4\text{NS}_2\text{PbOH}$  (II), which is dried at 110° and weighed as such. Any normal salt,  $(\text{C}_7\text{H}_4\text{NS}_2)_2\text{Pb}$ , is converted into (II) on boiling in presence of  $\text{NH}_3$ . Tl, Bi, and Au are similarly pptd. by (I).  $\text{C}_7\text{H}_4\text{NS}_2\text{Ti}$  is dried at 110°;  $(\text{C}_7\text{H}_4\text{NS}_2)_3\text{Bi}$  and  $(\text{C}_7\text{H}_4\text{NS}_2)_3\text{Au}$  are ignited to  $\text{Bi}_2\text{O}_3$  and Au, respectively.

J. S. A.

**Drop method for detection of cerium.** L. KULBERG (J. Appl. Chem. Russ., 1935, 8, 1452—1456).—Ag and  $\text{Ti}^{IV}$  are removed from 0.2 ml. of solution by pptn. as chlorides, 2—3 drops of saturated aq.  $\text{K}_4\text{Fe}(\text{CN})_6$ , 0.5 ml. of 10% KCN, and 3—4 drops of  $N\text{-NaOH}$  are added (to ppt. or neutralise the interfering effects of  $\text{Mn}^{II}$ ,  $\text{Co}^{II}$ , or  $\text{Th}^{III}$ ), and an  $\text{AcOH}$  solution of leuco-malachite-green is added, when a green coloration is obtained in presence of  $< 3 \times 10^{-8}$  g. of  $\text{Ce}^{III}$ .

R. T.

**Potentiometric determination of cerous salts with ferrocyanide.** P. SPACU (Z. anal. Chem., 1936, 104, 119—122).— $\text{Ce}^{III}$  is titrated potentiometrically against  $\text{K}_4\text{Fe}(\text{CN})_6$  in 30% aq. EtOH solution.

The Ce must be added to the  $K_4Fe(CN)_6$  to avoid adsorption errors. J. S. A.

**Colorimetric determination of aluminium in waters.**—See B., 1936, 222.

**Colorimetric determination of iron.** L. UR-BÁNYI (Mezőg. kutat., 1935, 8, 279—287).—The thiocyanic and sulphosalicylic acid reactions give inaccurate results. Comparison of the colours in the case of the Prussian-blue reaction is much easier. Best results were obtained when the acidity of the medium corresponded to 0.1N-HCl and the solution contained about 0.1—1.0 mg. of Fe per 10 ml.

NUTR. ABS. (m)

**Determination of ferric oxide.** A. F. FIOLETOVA and S. CHAIKINA (J. Appl. Chem. Russ., 1935, 8, 1467—1469).—Someya's Zn amalgam method is simpler and not less accurate than are the  $TiCl_3$  reduction, the iodometric, and the colorimetric methods. R. T.

**Determination of iron and manganese in water.**—See B., 1936, 254.

**Determination of cobalt by electrolysis at controlled potentials and using hydrazine hydrate and chloride as depolarisers.** A. JÍLEK and J. VŘEŠTAL (Coll. Czech. Chem. Comm., 1935, 7, 512—520).—The conditions for the quant. electrodeposition of Co have been investigated. < 100 mg. of Co are determined to within  $\pm 0.2$  mg. as a coherent, completely acid-sol. deposit by electrolysis at 4 volts and about 0.5 amp. with a rotating anode a solution of  $CoSO_4$  containing 0.5 g. of  $N_2H_4 \cdot HCl$ , 2 c.c. of conc.  $N_2H_4 \cdot H_2O$  (I), and 45 c.c. of conc. aq.  $NH_3$ , diluted to 100 c.c. After 1 hr., 1 c.c. of (I) is added and the electrolysis continued for 2 hr. Small quantities of Cl<sup>-</sup> have no effect, but the results are somewhat low with 1 g. of  $K_2SO_4$ , and with 1 g. of  $NH_4NO_3$ . Ni and Co-Ni mixtures can be determined under identical conditions. J. G. A. G.

**Volumetric determination of cobalticyanide ion.** R. UZEL and B. JEŽEK (Coll. Czech. Chem. Comm., 1935, 7, 497—511).—Electrometric titration of  $K_3Co(CN)_6$  with  $AgNO_3$  always gives results < stoichiometric owing to adsorption of  $Co(CN)_6^{3-}$  on colloidal  $Ag_3Co(CN)_6$ . Analogous results are obtained when  $Ag^+$  is replaced by  $Hg^+$ ,  $Hg^{2+}$ , and  $Cu^{2+}$ . With  $Cu^{2+}$ , the end-point becomes more vague as the at. wt. of the added univalent ion increases, but bi- and ter-valent ions do not interfere.  $K_2CrO_4$  indicates the stoichiometric end-point of the titration of  $Co(CN)_6^{3-}$  with  $AgNO_3$  even in the presence of  $Zn^{2+}$  and  $Mn^{2+}$  after boiling off excess of HCN in acid solution and neutralising. Ni, Fe, and other metals are eliminated earlier.  $Co(CN)_6^{3-}$  is formed from  $Co^{2+}$  by way of the intermediate brownish-red anion  $[Co^{III}(CN)_5OH]^{2-}$ . J. G. A. G.

**Volumetric determination of nickel in presence of cobalt.** G. CHARLOT (Bull. Soc. chim., 1936, [v], 3, 324—326).—The Ni and Co compounds are converted into  $K_4Ni(CN)_6$  and  $K_3Co(CN)_6$ , respectively, by the usual methods. By adding alkali, which ppt.  $Ni_2O_3$ , and then aq. HCl and  $H_2C_2O_4$ , the Ni complex is destroyed and  $NiCl_2$  obtained in solution, the Co complex being unchanged. Ni is then determined

volumetrically with KCN in aq.  $NH_3$  solution. The precision is 0.05—0.2 mg. of Ni. E. S. H.

**Oxidimetric determination of the oximes of nickel and copper.** J. MIRONOFF (Bull. Soc. chim. Belg., 1936, 45, 1—8).—The volumetric method described by Tougarnoff (A., 1935, 187) gives quant. results when small amounts of Cu and Ni are pptd. with phenylglyoxime (I), diacetylmonoxime (II), diphenylglyoxime (III), or benzoinoxime (IV). The same procedure as with dimethylglyoxime can be used for (I) and (II), but with (III) hydrolysis must be performed carefully on account of frothing. With (IV) the benzoin formed must be removed, or high results are obtained. J. W. S.

**Oxidation-reduction indicators. I. New indicators for the bromate titration of tin and antimony.** Z. RAICHINSCHTEIN (J. Appl. Chem. Russ., 1935, 8, 1470—1475).— $SnCl_2$  is titrated in 1.15N-HCl at 30—50° with 0.1N- $NaBrO_3$ , in presence of 0.1% benzopurpurin B.  $SbCl_3$  is titrated in 3.1—3.5N-HCl using benzopurpurin 4B as indicator. R. T.

**Precipitation of thorium by sebacic acid.** L. E. KAUFMAN (J. Appl. Chem. Russ., 1935, 8, 1520—1524).—3—10 ml. of 3% sebacic acid (I) in EtOH are added to 100 ml. of the boiling neutral solution, containing Th and Ce, the ppt. is collected, washed, dried at 100°, and warmed at 100° with fuming  $HNO_3$  to disappearance of  $NO_2$ , when the solution is evaporated to dryness, and dissolved in 100 ml. of  $H_2O$ . Th is then repptd. with (I), and the washed ppt. is calcined and weighed as  $ThO_2$ . R. T.

**Determination of oxides of vanadium in ores.**—See B., 1936, 191.

**Chemical differentiation of polished metallic minerals by the contact method. III, IV.** R. GALOPIN (Arch. Sci. phys. nat., 1935, [v], 17, Suppl., 252—257, 257—261; cf. A., 1935, 463).—Details are given for the detection of the minerals  $Sb_2S_3$ ,  $Bi_2S_3$ ,  $FeS$ ,  $Sb_2S_3$ ,  $3PbS$ ,  $Sb_2S_3$ ,  $2PbS$ ,  $Cu_2S$ ,  $Sb_2S_3$ ,  $NiS$ ,  $NiSb$ ,  $NiAs$ ,  $CuFeS_3$ ,  $Fe_3S_{n+1}$ , and  $(NiFe)S$ . R. S.

**Drop method of detection of bismuth.** N. A. TANANAIEV and A. V. TANANAIEVA (J. Appl. Chem. Russ., 1935, 8, 1457—1460).— $SnCl_2$  is added to the solution, when a brown coloration is given by  $\leq 2 \times 10^{-6}$  g. of Bi ( $Hg$  interferes). Alternatively, Ag and Pb are pptd. by saturated aq.  $NaCl-Na_2SO_4$  and  $SnCl_2$  and KI are added to the solution, when a yellow to orange ppt. is obtained in presence of  $\leq 10^{-5}$  g. of Bi. A third method consists in conversion into the chloride, followed by dilution, when  $BiOCl$  is pptd. ( $\leq 5 \times 10^{-5}$  g. of Bi). The limitations of the methods and their applications to special cases are discussed. R. T.

**Spectroscopic determination of adsorbed ions.** (Miss) M. ANNETTS and L. NEWMAN (J. Physical Chem., 1936, 40, 187—193).—The spectroscopic method for the determination of very small concns. of metal ions has been applied to the study of the action of NaOH and  $NaMnO_4$  as stabilising agents, and of  $AlCl_3$  as a coagulating agent, for Au sols, and also of  $MgCrO_4$  as a coagulating agent for Au and Cu sols. The limits of sensitivity are  $M/100,000$  for

Au and Mn,  $M/50,000$  for Mg, Cr, and Na, and  $M/1000$  for Al. M. S. B.

**Volumetric determination of palladium by means of oximes.** M. GAIHDE (Bull. Soc. chim. Belg., 1936, 45, 9—14; cf. this vol., 444).—Oximes of Pd cannot be hydrolysed and titrated directly like those of Cu and Ni. By pptn. with excess of standard salicylaldoxime in acid solution, filtering, and titrating the excess of oxime, 5—40 mg. Pd can be determined in presence of other metals. J. W. S.

**Use of overhead heating in analysis.** F. HEINRICH and F. PETZOLD (Chem.-Ztg., 1936, 60, 145—147).—Heating from above by electrical heating elements is recommended for rapid, quiet evaporation of liquids, drying of ppts., etc. R. S. C.

**Apparatus for measurement of thermal conductivity of metal foil.** A. EUCKEN and H. WARRENTUP (Z. tech. Physik, 1935, 16, 99—105; Chem. Zentr., 1935, ii, 191).—A centrally heated disc is used. Measurements on Cu and Al agree with previous data. J. S. A.

**Thermoregulator.** R. D. STEHLER (Science, 1936, 83, 40).—Increased precision is obtained by placing metal foil in the bulb of an ordinary PhMe regulator. L. S. T.

**Quantitative spectral analysis under variable discharge conditions.** V. NAEDLER (Compt. rend. Acad. Sci. U.R.S.S., 1935, 4, 23—26).—A discussion of errors in the use of a spark for excitation. H. J. E.

**Mercury-vapour lamp with very intense resonance radiation.** G. KORNFELD and F. MÜLLER-SKJOLD (Z. physikal. Chem., 1936, B, 31, 223—226).—A lamp is described which has an incandescent cathode of Konel metal and gives for 2537 Å. twelve times the intensity of the ordinary Hg-vapour lamp. R. C.

**Counter measurements and Röntgen unit.** H. WILHELM (Z. tech. Physik, 1935, 16, 2—8; Chem. Zentr., 1935, i, 3012—3013).—No general relationship between counter results and X-ray dose can be derived, but between limits of  $\lambda$ , and for homogeneous radiation, a fairly const. factor may be found. The use of counters for measurement of very weak X-ray doses is described. J. S. A.

**Photo-electric analysis with fluctuating light.** F. MÜLLER and W. DÜRICHEN (Chem. Fabr., 1935, 8, 267—269).—The insertion of a rotating perforated disc between the light source and the photo-electric cell gives rise to a fluctuating photo-electric current which may be amplified by means of thermionic valve circuits. The light intensity may be then reduced to give the max. sensitivity. Two barrier-layer cells may be used to provide a highly sensitive differential arrangement. J. S. A.

**Significance of ions in gas-filled photo-cells.** H. RICHTER (Z. tech. Physik, 1934, 15, 598—601; Chem. Zentr., 1935, i, 2951).—The relative importance of ionisation by collision, and of the formation of free electrons by bombardment of the cathode, has been investigated. By delaying the inception of the stable glow discharge, the performance of the cell may be improved. J. S. A.

H H

**Abnormalities in characteristic of vacuum photo-cells.** H. GEFFCKEN (Z. tech. Physik, 1934, 15, 595—598; Chem. Zentr., 1935, i, 2950—2951).—Vac. photo-cells in which the work of exit from the photosensitive layer is artificially lowered by suitable chemical treatment of that layer show irregular behaviour, the saturation current jumping reversibly from a lower to a higher val. The effect is not due to wall charges, but is attributed to changes in the cathodic space charge. Better compensation of space charges, and high sensitivity, may be attained by admission of traces of gas. J. S. A.

**Electrophotometer of barrier-layer [photo-] cells intended for practical opacimetry.** P. MEUNIER (Compt. rend., 1935, 201, 1371—1373). T. G. P.

**Photometric determination of m.p.** P. WOOG, J. GIVAUDON, R. SIGWALT, and J. LIENHART (Bull. Soc. chim., 1936, [v], 3, 439—442).—The fusion of the substance produces a "grease spot" on a paper screen, which is observed under unequal illumination from opposite sides, as in the Bunsen photometer. E. S. H.

**Shielded-filament X-ray tube for pure X-ray spectra.** E. DERSHEM (Rev. Sci. Instr., 1936, [ii], 7, 86—89).—The target is shielded from visible light and from spattered W from the filament. Fogging of plates by visible light is practically eliminated, the intensity of characteristic radiation remains const., the tube current is nearly const., and the life of the filament is increased. C. W. G.

**Apparatus for X-ray patterns of the high-pressure modifications of ice.** R. L. MCFARLAN (Rev. Sci. Instr., 1936, [ii], 7, 82—85).—Very rapid insertion and centring of the crystal, its rotation, and the evacuation of the diffraction chamber are possible. C. W. G.

**Influence of dispersion on the reading of the Haber-Löwe gas interferometer.** E. KARWAT (Z. Instrument., 1933, 53, 12—21, 70—78; Chem. Zentr., 1935, i, 3957). H. J. E.

**Simple comparator for absorption spectrograms.** F. ROSEBURY (Science, 1936, 83, 86). L. S. T.

$p_H$  measurements, dark-coloured substances, and indicator methods. F. ANSELM (Chem. Fabr., 1935, 8, 269—271).—The application of very thin colorimeter cells (up to 0.65 mm. thick) is described. J. S. A.

**Production of high-velocity lithium ions.** R. L. THORNTON and B. B. KINSEY (Physical Rev., 1934, [ii], 46, 324).—The arrangement described yields a current of 1.5 micro-amp. at  $5 \times 10^5$  volts. L. S. T.

**Superconducting galvanometer.** H. G. SMITH and F. G. A. TARR (Trans. Roy. Soc. Canada, 1935, [iii], 29, III, 23—35).—A moving-coil galvanometer, the coil of which is immersed in a liquid He cryostat, is described. H. J. E.

**Weston normal cell as standard for the international volt.** A. K. KOLOSOV (Vses. Nauch.-Issled. Inst. Metrol., 1932, No. 100, 131—137; cf. A., 1934, 625).—To avoid mixing of the components

during transport, the cathode limb has a constriction to hold the Hg in place. The saturated  $\text{CdSO}_4$  contains approx.  $0.004N\text{-H}_2\text{SO}_4$ . In washing the  $\text{Hg}_2\text{SO}_4$  with saturated aq.  $\text{CdSO}_4$  washing must cease when the concn. of acid in the washings is  $0.004N$ . High acid concns. lead to gas formation in the anode limb.

CH. ABS. (e)

**Resolving power in recording of coincidence by two counters arranged behind one another.** J. N. HUMMEL (Z. tech. Physik, 1934, 15, 573—575; Physikal. Z., 1934, 35, 997—999; Chem. Zentr., 1935, i, 2942).—Data concerning resolving power are given.

J. S. A.

**Sensitive counter tube arrangement.** E. B. ANDERSEN (Z. Physik, 1936, 98, 597—604).—A counter for weak radioactive measurements is surrounded by other tubes, and the amplifier registers those impulses present only in this tube.

A. B. D. C.

**Determination of the end-point of conductometric titrations by calculation.** J. H. BOULAD (Bull. Soc. chim., 1936, [v], 3, 408—412).—Mathematical procedure, replacing the graphical method, is described.

E. S. H.

**Easily constructed electrical relay.** G. F. KOEPF and J. F. MEZEN (Science, 1936, 83, 109—110).

L. S. T.

**Iron-free coil for production of maintained intense magnetic fields.** G. GERLOFF and E. LÖWE (Z. Physik, 1936, 98, 559—560).—The apparatus gives homogeneous fields up to 5000 oersted.

A. B. D. C.

**Pipette for measurement of aqueous solutions.** Y. P. LIU (J. Chinese Chem. Soc., 1936, 4, 20—21).—The pipette is provided with a two-way stopcock above the bulb.

R. S. B.

**Micro-burette.** W. SPATZ (Chem. Fabr., 1936, 9, 70).—A capillary connecting tube avoids the formation of air bubbles between the burette and the reservoir.

J. S. A.

**Apparatus for determination of gases.** M. L. JEAN (Bull. Soc. chim., 1936, [v], 3, 267—269).—The apparatus formerly described (A., 1935, 466) is modified.

E. S. H.

**Accessories for gas analysis.** W. ALLNER (Chem. Fabr., 1936, 9, 70—72).—A device for collecting gases at const. variable pressure, and a modified Jaeger  $\text{CuO}$  tube for the fractional combustion of  $\text{H}_2$  and hydrocarbons, are described.

J. S. A.

**Constant-volume gas analysis apparatus.** B. N. SINGH and P. B. MATHUR (Biochem. J., 1936, 30, 321—322).—The apparatus is used for determination of  $\text{O}_2$  and  $\text{CO}_2$  with an accuracy of  $\pm 0.1\%$ .

W. McC.

**Multiple-unit distilling apparatus for determination of fluorine by Willard and Winter's method.** D. S. REYNOLDS, I. B. KERSHAW, and K. D. JACOB (J. Assoc. Off. Agric. Chem., 1936, 19, 156—162; cf. A., 1933, 242, 654).

E. C. S.

**Preparation of glass helices for use in fractionating columns.** W. C. YOUNG and Z. JASAITIS (J. Amer. Chem. Soc., 1936, 58, 377).—Technique is recommended.

E. S. H.

**Determination of Poisson's elastic constants by means of ultrasonic waves.** R. BAR and A. WALTI (Helv. phys. Acta, 1934, 7, 658—661; Chem. Zentr., 1935, i, 3759).—The method is applied to the determination of the elastic moduli of glass.

J. S. A.

**Air-damped balances.** W. N. BOND (Analyst, 1936, 61, 85—90).—The theoretical and practical advantages of critically air-damped over oscillating balances are discussed.

E. C. S.

**Constant-level siphon.** R. LAUTIE (Bull. Soc. chim., 1936, [v], 3, 503—504).

E. S. H.

**Level control in funnels.** W. R. THOMPSON (Science, 1936, 83, 168).

L. S. T.

**Apparatus for catalytic hydrogenation at high pressure.** L. PALFRAY (Bull. Soc. chim., 1936, [v], 3, 508—511).—The apparatus consists of an autoclave and  $\text{H}_2$  compressor, with automatic recording of temp. and pressure. It is suitable for the range  $0\text{--}300\text{ kg.}$  and  $0\text{--}300^\circ$ .

E. S. H.

**Determination of density of grains.** W. F. DE JONG (Zentr. Min., 1935, A, 140—142; Chem. Zentr., 1935, ii, 252).—A flotation method, applicable to particles weighing about 1 mg., is described.

J. S. A.

**Improvised micro-manipulator.** P. H. SIMONS (J. S. African Chem. Inst., 1936, 19, 24—25).—The adjustments of a microscope sub-stage condenser may be used to manipulate needles, capillaries, etc. in the field of the microscope.

J. S. A.

**Determination of contact angles from measurements of the dimensions of small bubbles and drops.** I. Spheroidal segment method for acute angles. G. L. MACK. II. Sessile drop method for obtuse angles. G. L. MACK and (Miss) D. A. LEE (J. Physical Chem., 1936, 40, 159—167, 169—176).—I. Acute angles of contact may be determined as a function of the radius and vol. of a small spherical drop of liquid by a method which is practically independent of the solid surface concerned. An expression for the effect of gravity on the form of the drop is given.

II. Average obtuse contact angles may be determined from measurements of the vertical height, the horizontal radius, and the radius of curvature at the apex of sessile drops or bubbles under a plate. The third dimension required may be calc. from the capillary const. of the liquid by a simplified equation.

M. S. B.

**Apparatus for maintaining circulation of gases in laboratory apparatus.** V. I. KUZNETZOV (J. Appl. Chem. Russ., 1935, 8, 1516—1517).—A simple laboratory pump is described.

R. T.

**Safety tube for preventing bumping of liquids supersaturated with gas.** V. I. KUZNETZOV (J. Appl. Chem. Russ., 1935, 8, 1514—1515).—A U-tube, containing 1—2 drops of Hg, with one broad and one narrow limb, is fused to the lower part of the condenser tube of a Kjeldahl set. The tube, by allowing gases to enter, but not to leave, the apparatus, permits instant equalisation of pressure, thereby eliminating bumping.

R. T.

**Research applications of colloidal graphite.** B. H. PORTER (Rev. Sci. Instr., 1936, [ii], 7, 101—106).—Applications to vac. technique, electronic devices, electrical contacts, and other purposes are described. C. W. G.

**Determination of vapour pressure.** V. A. KIREEV and A. A. POPOV (J. Gen. Chem. Russ., 1935, 5, 1399—1401).—Apparatus is described, whereby the v.p. of  $\text{AcCl}$ ,  $\text{CH}_2\text{Cl}\cdot\text{CO}_2\text{H}$ , and propylene oxide have been measured at different temp., and empirical equations connecting temp. with v.p. have hence been derived. R. T.

**Glass apparatus for handling low-b.p. liquids.** S. F. BIRCH and P. DOCKSEY (Chem. and Ind., 1936, 169—170).—The construction of a simple apparatus which can be used also for the solvent extraction of liquids is described. S. M.

**Mixing arrangement for large quantities in the laboratory.** B. FLASCHENTRÄGER and P. FABER (Chem. Fabr., 1935, 8, 272).—A rotary shaking machine is described. J. S. A.

**Determination of surface tension by the drop-weight method.** K. C. BAILEY (Nature, 1936, 137, 323). L. S. T.

**Ripple method of measuring surface tension.** R. C. BROWN (Proc. Physical Soc., 1936, 48, 312—322).—An apparatus for the production, stroboscopic observation, and measurement of ripples for surface-tension determinations is described. Results for the fall of surface tension of a slowly adsorbed aq. solution of cetylpyridinium bromide are similar to those obtained by a static method, showing that the ripples do not retard attainment of surface equilibrium. N. M. B.

**Measurement of surface tension by means of stationary waves on a vertical jet.** J. SATTERLY and J. C. STRACHAN (Trans. Roy. Soc. Canada, 1935, [iii], 29, III, 105—112).—Measurements with  $\text{H}_2\text{O}$  and  $\text{Hg}$  are described, using a modification of Satterly and McPherson's method (*ibid.*, 1934, 28, 177). Sources of error are discussed. H. J. E.

**Determination of viscosity by the oscillation of a vessel enclosing a fluid.** I. E. N. DA C. ANDRADE and Y. S. CHONG. II. E. N. DA C. ANDRADE and L. ROTHERHAM (Proc. Physical Soc., 1936, 48, 247—260, 261—266).—I. An improved technique and method of calculation are described. Accurate results are obtained for  $\text{H}_2\text{O}$  over the temp. range 2.5—65.2°.

II. Instead of the energy of oscillation being dissipated by the viscous forces, energy is supplied at every oscillation, by the discharge of a condenser, to maintain a fixed amplitude;  $\eta$  is calc. from the amplitude and the energy supplied. The method is checked by measurements of  $\eta$  for hexane in terms of that of  $\text{H}_2\text{O}$ . N. M. B.

**Arrangement for measuring the viscosity of gases.** A. FORTIER (Compt. rend., 1935, 201, 1330—1332).—A method which depends on delivering a rigorously const. vol. of gas independent of the pressure and of the capillary is outlined. T. G. P.

**Measurement of absolute viscosity by the falling-sphere method.** L. R. BACON (J. Franklin Inst., 1936, 221, 251—273).—The vals. given by Stokes' formula are shown to depend on the ratio diameter of sphere/diameter of tube. Various correction formulæ have been tested, but only that due to Faxen yields vals. in agreement with capillary-tube determinations over the range 10—10,000 poises. R. S.

**Apparatus for automatically maintaining reduced pressure.** C. F. WINCHESTER (Science, 1936, 83, 64). L. S. T.

**Instruments for registration of vapour pressure [of water] and specific humidity.** F. WENK (Z. Instrument., 1935, 54, 15—19; Chem. Zentr., 1935, i, 3957).—Apparatus is described. J. S. A.

**Vacuum in laboratory and technique.** H. BAERMANN (Chem. Fabr., 1935, 8, 395—404).—A comprehensive review covering modern types of vac. pumps, measuring instruments, vac. sealing media, automatic regulators, and vac. evaporating and distilling technique. A. R. P.

## Geochemistry.

**Spectra of meteors.** P. M. MILLMAN (Ann. Ast. Obs. Harvard Coll., 1932, 82, 113—146).—9 spectra are discussed. Fe, Ca, Mg, Mn, Al, Cr, and Si were identified. CH. ABS. (e)

**Evolution of helium from the earth.** E. K. GERLING (Compt. rend. Acad. Sci. U.R.S.S., 1935, 4, 41—43).—Analyses are recorded for the  $\text{He}+\text{Ne}$  content of air in contact with the earth in various districts. In none of the localities examined was the val. high. H. J. E.

**Lake Akanuma, a siderotrophic lake at the foot of volcano Bandai, Hukusima Prefecture, Japan.** S. YOSHIMURA (Proc. Imp. Acad. Tokyo, 1935, 11, 426—428).—The temp.,  $p_{\text{H}}$ ,  $[\text{O}_2]$ ,  $[\text{Mn}]$ ,  $[\text{Fe}]$ ,  $[\text{Cl}]$ , and sp. conductivity are recorded for samples of  $\text{H}_2\text{O}$  from the surface and from various

depths. The absence of dissolved  $\text{O}_2$  at 1 m. and below is due to reduction by  $\text{Fe}^{++}$  and  $\text{Mn}^{++}$ , which are present in high concn. The high conductivity is due to  $\text{CaSO}_4$ . J. W. S.

**Radioactive waters at Starobelsk.** E. S. BURKSER (Compt. rend. Acad. Sci. U.R.S.S., 1935, 4, 45—48).—Complete analytical data are given for samples from depths of 400—750 m. The Ra content was 0.80—6.1  $\times 10^{-11}\%$ . Th and mesothorium were absent. H. J. E.

**Mineral and medicinal springs of Switzerland.** ANON. (Mitt. Lebensm. Hyg., 1935, 26, 250—328).—Analyses of 62 springs are given and a system of classification is evolved based on mineral constituents, physical properties, and clinical effects. J. G.

**Characteristics of Pearl River water.** W. W. HUANG (J. Chem. Eng. China, 1935, 2, 139—147).—Seasonal variations in chemical composition of this H<sub>2</sub>O are recorded in detail. C. I.

**Corpus Christi structural basin postulated from salinity data.** W. A. PRICE (Bull. Amer. Assoc. Petrol. Geol., 1935, 19, 317—355).—Consideration of lines of isoalkalinity indicates that original oceanic H<sub>2</sub>O diluted with surface H<sub>2</sub>O entered at the outcrop and penetrated slowly down the dip.

CH. ABS. (p)

**Difference in the isotopic composition of the oxygen in air and water.** N. MORITA and T. TITANI (Bull. Chem. Soc. Japan, 1936, 11, 36—38).—By preparing H<sub>2</sub>O from light H<sub>2</sub> and from O<sub>2</sub> obtained (1) from the air, (2) by the partial electrolysis (5%) of ordinary H<sub>2</sub>O, and (3) by the complete hydrolysis of H<sub>2</sub>O, and by comparing  $\delta$  for the three samples, it has been shown that air is richer in O<sup>18</sup> than ordinary H<sub>2</sub>O. The distribution coeff. of O<sup>18</sup> between air and H<sub>2</sub>O is approx. 1.04. M. S. B.

**Analyses of phosphorite from the culm formation of the Świetykrzyż mountains.** S. BISKUPSKI (Bull. Acad. Polonaise, 1935, A, 85—91).—Analytical data are recorded and discussed. The Ca<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub> content increases and that of CaCO<sub>3</sub> decreases with the age. The CaF<sub>2</sub> was almost const. in all the phosphorites. H. J. E.

**Origin of guano minerals in the Dominican Grotto, Slovakia.** J. V. KAŠPAR (Věstn. Stát. Geol. Úst. Českoslov. Repub., 1934, 10, 104—111; Chem. Zentr., 1935, i, 3527).—Analytical data are given. H. J. E.

**Symmetrical extinction angles of albite-twinned plagioclases.** S. TSUBOI (Proc. Imp. Acad. Tokyo, 1935, 11, 423—425).—The curve given by Wright (Amer. J. Sci., 1913, 36, Plate X) for the max. symmetrical extinction angles of albite-twinned plagioclases is shown to be incorrect and a revised curve is given. J. W. S.

**Relations of later gabbro to sulphides at the Horne Mine, Noranda, Quebec.** G. G. SUFFEL (Econ. Geol., 1935, 30, 905—915).—Sulphide ores at this mine are definitely later than all other formations except, possibly, the later gabbro dykes. All the chalcopryite, and probably the pyrrhotite and pyrite, are now shown to be post-dyke. L. S. T.

**Differentiation in traps and ore deposition.** A. C. LANE (Econ. Geol., 1935, 30, 924—927; of. A., 1935, 955).—A discussion. L. S. T.

**Mylonitic sphalerite from Friedensville, Pennsylvania.** R. D. BUTLER (Econ. Geol., 1935, 30, 890—904). L. S. T.

**Large quartz veins of Great Bear Lake, Canada.** G. M. FURNIVAL (Econ. Geol., 1935, 30, 843—859).—These have been formed by the deposition of quartz (I) from hydrothermal solutions at moderate temp. Minerals other than (I) are sparse and represent last-stage depositions. They are specular hematite, bornite, chalcopryite, covellite, chalcocite, pyrite, famatinite, and siderite. Pitchblende has also been found in a large vein on Hottah Lake. The extensive

alteration and replacement of the severely-fractured wall rocks by SiO<sub>2</sub> which accompanied the formation of the veins is described in detail. Analyses showing the chemical changes during alteration and a diagram showing gains and losses of oxides are given. The genetic relations of the veins are also discussed. L. S. T.

**Geologic problems of the Canadian Pre-Cambrian gold fields.** E. Y. DOUGHERTY (Econ. Geol., 1935, 30, 879—889).—Problems relevant to the science of ore deposits and to the practice of mining geology are discussed. L. S. T.

**Natural glasses of the insoluble residues of the Pennsylvanian limestones of Texas.** L. T. PATTON (Science, 1936, 83, 83—84). L. S. T.

**Origin of cyanite.** S. TABER (Econ. Geol., 1935, 30, 923—924; cf. A., 1935, 954). L. S. T.

**Synthetic emerald.** EPPLER (Deut. Goldschmiede-Ztg., 1935, 38, 144—146; Chem. Zentr., 1935, i, 3969).—Optical data are given for distinguishing natural from synthetic emeralds. J. S. A.

**Relations of amphibolites and peridotites at Sarrazac (Dordogne).** M. ROQUES (Compt. rend., 1936, 202, 332—334).—The rocks are described and their relationships are discussed. Analyses are given. H. J. E.

**Assimilation processes, formation of migmatites, and their signification in the origin of magmas.** F. K. DRESCHER-KADEN (Chem. Erde, 1936, 10, 271—310).—Cases of rock variation around granite and gabbro masses at various well-known localities, which have hitherto been ascribed to differentiation of the magma, are now asserted to be due to assimilation of the surrounding rocks into which the magma was intruded, with the production of migmatites or mixed rocks. The bearing of this on the origin of magmas and on petrological theory is discussed (cf. Reynolds, A., 1935, 1477). L. J. S.

**Copper-bearing spathic iron veins in the Bober-Katzbach Mtns., Silesia.** A. NEUHATS (Chem. Erde, 1936, 10, 247—270; Fortschr. Min. Krist. Petr., 1936, 20, 50—55).—These veins were discovered in 1922 and have been worked for Fe and Cu ores. The principal mineral is chalybite (containing 3% Mn), and the Cu ore is mainly chalcopryite with associated rarer Ni and Co minerals. A detailed description is given and the origin of the veins discussed. L. J. S.

**Geochemistry of barium.** W. VON ENGELHARDT (Chem. Erde, 1936, 10, 187—246).—Numerous igneous and sedimentary rocks, minerals, meteorites, and org. plant remains were examined spectroscopically for Ba. In igneous rocks Ba goes with K, ranging from 0.2% BaO in syenite to 0.0003% in peridotite, with an average of 0.048%. In sedimentary rocks it is adsorbed by clay, clay-slates containing BaO 0.05% and limestone 0.01%. The average for the whole lithosphere is 0.045%. The deposition of baryte under various conditions is discussed. L. J. S.

**Rocks from Cape Verde Islands.** H. ERMERT (Chem. Erde, 1936, 10, 155—186).—A collection of rocks from the islands of São Vicente and Sal is

described, with chemical analyses of foyaite, dioritic essexite, trachyandesite, gabbroid essexite-dolerite, and augite. These when tabulated and plotted with earlier analyses show a similarity to the rocks of the Canary Islands, and the two form a rock province characterised by the predominance of  $\text{Na}_2\text{O}$ . Mineral analyses are given of sands from the same islands.

L. J. S.

**Synthesis of montmorillonite.** W. NOLL (Chem. Erde, 1936, 10, 129—154; cf. A., 1935, 601).—In presence of little alkali both montmorillonite (I) and kaolin are formed; with still less or none (or in a slightly acid solution) only kaolin. With an excess of  $\text{NaOH}$  analcime is formed. Similar results are obtained in presence of  $\text{Ca}(\text{OH})_2$  and  $\text{Mg}(\text{OH})_2$ . With excess of  $\text{Mg}(\text{OH})_2$  this enters into the composition of the (I) up to 15.3%  $\text{MgO}$ , which then corresponds with a fuller's earth. In the natural formation of clay minerals by the hydrothermal alteration of rocks, if alkalis accumulate, owing to feeble circulation, then (I) is formed, whilst if they are removed by an excess of  $\text{H}_2\text{O}$  kaolin is formed.

L. J. S.

**Rock-forming minerals from Belgian Congo.** A. VANDENDRIESSCHE (Natuurwetensch. Tijds., 1936, 17, 243—247).—The crystallography, physical properties, and chemical analyses of olivine and augite from near the Mikenov volcano, Kivu, are given. These minerals occur in soil derived from basaltic lavas.

D. R. D.

**Colour of corundum.** I. I. ISLAMOV and J. M. TOLMATSHEV (Compt. rend. Acad. Sci. U.R.S.S., 1936, 1, 11—13).—Corundums have been analysed spectroscopically, the red form containing Cr 0.18, Ti 0.01, V 0.04, and Ga 0.005%, the blue, Cr 0.002, Ti 0.2, V trace, and Ga 0.005%, and the light grey, Cr trace, Ti 0.03, V trace, and Ga 0.002%. Fe is present in approx. the same amount in each. A qualitative analysis has been made for other elements in corundum, and on disthene. The cause of colour is discussed.

R. S. B.

**Optical diagram for magnesium-iron mica (phlogopite).** D. P. GRIGORIEV (Zentr. Min., 1935, A, 142—150; Chem. Zentr., 1935, ii, 198).—The variation of the optic axial angle and refractivity of phlogopite with the  $\text{FeO}$  content deviates widely from the theoretical curve. The cause is discussed.

J. S. A.

**Classification of the granites of the southern Katanga according to the planimetric study of thin sections.** M. GYSIN (Arch. Sci. phys. nat., 1935, [v], 17, Suppl., 243—246).—The granites can be divided into 8 classes, belonging to the granitic or dioritic groups of the calco-alkaline series.

R. S.

**Luminescence of calcite (with special reference to the Polish deposits).** S. KREUTZ (Bull. Acad. Polonaise, 1935, A, 486—500).—Specimens of calcite were heated to 300°, 330°, 360°, 530°, 680°, and red heat, and, on cooling, their luminescence was examined. Luminescence is lost on heating, this fact being connected with loss of  $\text{CO}_2$ . The blue luminescence of some samples changes to a bright yellow between 330° and 580°. Although the luminescence of specimens from different localities differs, there are

two main spectral ranges, one in the red, and the other in the blue and violet. The phosphorescence exhibited by some specimens of calcite was also investigated.

A. J. M.

**Origin of tektites. I. Tektites as fulgurites [formed in the atmosphere].** T. VOGT (Kong. Norske Vidensk. Selsk. Forh., 1935, 8, 9—12; Chem. Zentr., 1935, i, 3527).

H. J. E.

**Preservation of pyrite and marcasite.** F. A. BANNISTER (Museums J. London, 1933, 33, 72—75).—The decomp. of specimens of natural  $\text{FeS}_2$  can be arrested by cleaning with aq.  $\text{NH}_3$ , washing, drying at 70°, and coating with a 7% solution of vinyl acetate in 1:1  $\text{PhMe-COMe}_2$ .

CH. ABS. (e)

**Lovchorrite of the Chiba swamps.** I. K. CHAZANOVITSCH (Razved. Nedr, 1935, 4, No. 1, 28).—Lovchorrite contains approx. 16% of Ce and Ce earths, 1% of Th, and some U. It resembles glue plates. Chibinite is similar.

CH. ABS. (e)

**Lake Bosumtwi [volcanic glass].** N. R. JUNNER (Rep. Geol. Surv. Gold Coast, 1932—1933, 4—7).—The volcanic glass contained 64.01% of  $\text{SiO}_2$ .

CH. ABS. (e)

**Preliminary staining studies of the Lehigh Valley dolomitic limestone.** J. FULLER (Proc. Penna. Acad. Sci., 1934, 8, 83—87; Rev. géol., 14, 522).—Staining tests distinguish dolomitic from  $\text{MgO}$ -free limestones. Malachite-green and  $\text{K}_4\text{Fe}(\text{CN})_6$  with  $\text{HCl}$  are satisfactory. Lemberg's solution gives the best results.

CH. ABS. (e)

**Iron deposits of southern Anhui.** C. Y. HSIEH (Bull. Geol. Soc. China, 1931, 10, 317—347).—The Fe ores are genetically related to diorite intrusions, and are of the contact metamorphic and hydrothermal types. In the former, magnetite occurs with garnet and babingtonite.

CH. ABS. (e)

**Genesis of the Mivirando tin ores.** W. C. SIMMONS (Ann. Rep. Geol. Survey Uganda, 1932, 50—52; Rev. géol., 14, 290).—It is suggested that Sn came up as K stannate, which, on meeting  $\text{Al}_2\text{O}_3$  and  $\text{SiO}_2$ , deposited cassiterite and muscovite. The alkali manganates, tungstates, titanates, etc. may transport the respective metals.

CH. ABS. (e)

**Occurrence and distribution of staurolite in Gangpur State, Bihar and Orissa.** M. S. KRISHNAN (Quart. J. Geol. Soc. India, 1933, 5, 67—73).—Staurolite occurs in mica-schists with quartz, biotite, muscovite, penninite, and garnet.

CH. ABS. (e)

**Correlation between specific gravity, chemical constitution, and condition of formation of minerals and rocks.** D. C. NAG (Quart. J. Geol. Soc. India, 1932, 4, 29—67).—The  $d$  has been calc. from analyses, assuming the mol. vol. of a compound equal to the sum of the mol. vols. of its constituents.

CH. ABS. (e)

**Geology of the Orkneys.** G. V. WILSON, W. EDWARDS, J. KNOX, R. C. B. JONES, J. V. STEPHENS, and J. S. FLETT (Mem. Geol. Survey Scotland, 1935, 205 pp.).—Deposits of galena associated with strombolite, and the petrography of numerous basic dikes, are described. Analyses are given.

CH. ABS. (e)

**Minerals in diamondiferous concentrates.** N. R. JUNNER (Rep. Geol. Survey Gold Coast, 1932—1933, 14—15).—Diamonds are often enclosed in pisolites of limonite with 0.15—1.19% of  $\text{Cr}_2\text{O}_3$ . This suggests their origin from ultra-basic igneous rocks. Analyses of garnets, ilmenite, and chrysoberyl are given. CH. ABS. (e)

**Arrangement of micro-crystals of silica in the onyx.** M. ICHINOSE (Mem. Coll. Sci. Kyoto., 1935, A, 18, 315—316).—X-Ray diffraction patterns show that micro-crystals of  $\text{SiO}_2$  in onyx have a fibrous arrangement, of which the common axis is [1120] and perpendicular to the surfaces of the banded layers in the mineral. J. G. A. G.

**Iron formations and associated rocks of the Eastern Bababudans, Kadur District, Mysore.** C. S. PICHAMUTHU (J. Mysore Univ., 1935, 8, 1—48).—Analyses are given, and the origin of the banded ferruginous quartzites is discussed. C. W. G.

**Viscosity of fused rocks.** M. VOLAROVITSCH (Compt. rend., 1936, 202, 78—80; cf. A., 1934, 751).—Analytical and  $\eta$  data (1110—1400°) are recorded for a series of rocks.  $\eta$  increases, in general, with the acidity of the rock. H. J. E.

**Violet fluorspars.** H. ARSANDAUX (Bull. Soc. franç. Min., 1935, 58, 268—277).—When slowly heated, strongly-coloured fluorspars emit a relatively prolonged thermoluminescence, which approx.  $\propto$  the intensity of pigmentation. They differ from most coloured fluorspars in emitting little or no fluorescence under the action of ultra-violet light until they have been decolorised by heat. The violet fluorspar from the Isle quarry, near Limoges, is described in detail. Mn may be responsible for the fluorescence in this case. L. S. T.

**Hydroxides of aluminium of the bauxitic clays of Ayrshire.** J. DE LAPPARENT (Bull. Soc. franç. Min., 1935, 58, 246—267).—These clays contain a large amount of boehmite (I) and a small quantity of diaspore (II). The origin of (I) and (II), which is formed after (I), is discussed. L. S. T.

**Elasticity and plasticity of rocks and artificial stone.** R. H. EVANS (Proc. Leeds Phil. Soc., 1935—1936, 3, 145—158).—Tests on numerous specimens in tension and compression are described and discussed. H. J. E.

**Andesites of the Trojaga District in the Mar-moros Carpathians.** M. KAMIENSKI (Bull. Acad. Polonaise, 1935, A, 399—407).—Microscopical and chemical investigations of the volcanic rocks of the Trojaga indicate that they belong to the calc-alkali series of the amphibole-andesites and amphibole-biotite-andesites which show the character of dacitoids. They were probably erupted in the second Mediterranean or the Samet epoch. T. G. P.

**Morphological studies of enargite.** S. KÔZU and S. WATANABÉ (Proc. Imp. Acad. Tokyo, 1935, 11, 418—420; cf. A., 1934, 244, 1060).—Examination of many crystals of enargite ( $\text{Cu}_3\text{AsS}_4$ ) leads to the conclusion that this crystal is hemimorphic. Its crystal habit and modes of twinning are discussed. J. W. S.

**Space-group and cell dimensions of enargite.** S. KÔZU and K. TAKANÉ (Proc. Imp. Acad. Tokyo, 1935, 11, 421—422; cf. preceding abstract).—Re-examination of the X-ray reflexions of enargite crystals indicates the cell dimensions  $a_0$  6.39,  $b_0$  7.35,  $c_0$  6.15 Å. with two  $\text{Cu}_3\text{AsS}_4$  mols. per unit cell. It is concluded that the space-group is  $C_{2v}^n$ . J. W. S.

**Chemical formula of malachite.** M. GUILLOT and G. GENESLAY (Compt. rend., 1936, 202, 136—137).—Artificial malachite ( $8\text{CuO} \cdot 4\text{CO}_2 \cdot 5\text{H}_2\text{O}$ ) identical with the natural product may be prepared by (a) the action of saturated aq.  $\text{Na}_2\text{CO}_3$  or  $\text{NaHCO}_3$  on saturated aq.  $\text{CuSO}_4$  or (b) the hydrolysis of alkali cupricarbonates or  $\text{Cu}^{\text{II}}$  "carboxydiammine." T. G. P.

**Heavy mineral assemblage of white clay and ochres associated with the laterite of Sohawal State, central India.** N. L. SHARMA and S. PURKAYASTHA (Quart. J. Geol. Soc. India, 1934, 6, 49—54). CH. ABS. (e)

**Petrography of clay.** C. W. CORRENS (Naturwiss., 1936, 24, 117—124).—The distribution of nuclear size of clay particles in different specimens of clay, and the examination of the constituents of clay by microscopical and X-ray methods, are discussed. The effect of  $\text{HCl}$ ,  $\text{NaOH}$ , and  $\text{H}_2\text{O}_2$  of various concns. is reviewed.  $\text{H}_2\text{O}_2$  is without appreciable action. A. J. M.

**Transformation of absorbed anions in Ad-sharien red earth.** B. B. POLINOV (Compt. rend. Acad. Sci. U.R.S.S., 1935, 4, 49—50).—Analytical data are given showing the displacement of adsorbed  $\text{Cl}'$  and  $\text{SO}_4''$  on treating samples of the soil with 0.1N- $\text{NaH}_2\text{PO}_4$ . H. J. E.

**Podolian loess.** I. Petrographical analysis of a loess profile from Grzybowice near Lwow. J. TOKARSKI (Bull. Acad. Polonaise, 1935, A, 374—398).—Microscopical and chemical investigations in 10 horizons indicate that the deposit belongs to the latest diluvial epoch. The loess exhibits only slight genetic relationship to the Tertiary sand of Lwow. T. G. P.

**Marine oil shale, source of oil in Playa del Rey field, California.** H. W. HOOTS, A. L. BLOUNT, and P. H. JONES (Bull. Amer. Assoc. Petrol. Geol., 1935, 19, 172—205).—The migration of oil in the field is discussed. CH. ABS. (e)

**Native hydrocarbons associated with oil shales of the Lothians.** H. R. J. CONACHER (Trans. Edinburgh Geol. Soc., 1934, 13, 89—97).—Chrimatite (m.p. 51°) occurs in cavities in igneous rocks. Zietrisikite (m.p. 84°) occurs in joints in sandstone. Wurtzilite (m.p. 130°) is found in oil shales and ironstone nodules, and resembles ixolite. CH. ABS. (e)

**Oil deposits in the Lena river basin and its tributaries (Siberia). Organic substance of the minerals from the river Tolba.** S. P. USPENSKI (Nef. Choz., 1935, 27, No. 2, 29—32).—Analyses are recorded and discussed. CH. ABS. (e)

**Migration of Hungarian hydrocarbons.** E. R. SCHMIDT (Föld. Közlöny, 1934, 64, 278; Chem. Zentr., 1935, i, 3527).—A discussion. H. J. E.

## Organic Chemistry.

Appearance of radicals in thermal decomposition of organic molecules.—See this vol., 433.

Thermal decomposition of ethane. I, II. See this vol., 432.

Free radicals and atoms in primary photochemical processes. Free *n*-propyl radical. T. G. PEARSON and R. H. PURCELL (J.C.S., 1936, 253–256).—Formation of  $\text{Pr}^\bullet$  by irradiation of  $\text{COPr}^\bullet$ , with ultra-violet light (A., 1935, 1221) is proved by removal of As, Sb, and Te mirrors and reaction with Hg (forms a liquid, which with  $\text{HgBr}_2$  gives  $\text{HgPr}^\bullet\text{Br}$ ); excitation of the Hg is avoided by filtration of the irradiating light through Hg vapour. The half-life period of  $\text{Pr}^\bullet$  is  $2.3 \times 10^{-3}$  sec. in  $\text{SiO}_2$  at room temp. R. S. C.

Preparation of isomeric hexanes. P. L. CRAMER and M. J. MULLIGAN (J. Amer. Chem. Soc., 1936, 58, 373–374).—*n*-Hexane, b.p. 68.74–68.78° ( $\text{CH}_3\text{EtPr}^\bullet\text{OH}$ ;  $\text{Al}_2\text{O}_3$  at 350°),  $\beta$ -methylpentane, b.p. 60.22–60.26° ( $\text{CMe}_2\text{Pr}^\bullet\text{OH}$ ; I at 122°),  $\gamma$ -methylpentane, b.p. 63.16–63.21° ( $\text{CMeEt}_2\text{OH}$ ; I at 120°),  $\beta$ -dimethylbutane, b.p. 49.8–49.82° ( $\text{CHMeBu}^\bullet\text{OAc}$  heated at 400°), and  $\beta$ - $\gamma$ -dimethylbutane, b.p. 57.82–58.02° ( $\text{OH}^\bullet\text{CMe}_2\text{CMe}_2\text{OH}$ ;  $\text{HBr}$  at 130–150°), are prepared by reduction ( $\text{H}_2$ ,  $\text{PtO}_2$ ) of the olefines formed by dehydration (methods quoted) of the alcohols quoted after the hydrocarbons. H. B.

Thermal study of oxidation of hydrocarbons.—See this vol., 432.

Polarisability of the ethylenic linking. G. WITTO (Ber., 1936, 69, [B], 471–475).—The additive capacity of the C:C linking in  $\text{CR}_2\text{:CR}_2$  depends on the nature of the addendum and on that of R. The displacability of the valency electrons on deformation of the state of union of the C:C group is much more pronounced than that of the C:C linking, and this reacts on R. Examples cited are the ability of  $\text{CHMe}^\bullet\text{CH}^\bullet\text{CHO}$  to undergo the aldol condensation, the fission of  $\text{CPh}_2\text{:CH}^\bullet\text{CH}_2^\bullet[\text{CH}_2\text{:CH}^\bullet\text{CPh}_2]$  by alkali metal, the pinacolin transformation of  $[\text{OH}^\bullet\text{CPhR}^\bullet\text{C}]_2$ , the action of NaOH on 2:6:3-( $\text{NO}_2$ ) $_2\text{C}_6\text{H}_2\text{Me}^\bullet\text{CHO}$ , and the dissimilarity in the behaviour of 2- and 4-pyrones. The conditions for the realisation of valency tautomerism are discussed. H. W.

Raman spectrum of rubber and related hydrocarbons. See this vol., 407.

Preparation of unsaturated hydrocarbons by elimination of halogen acids from corresponding halides. A. BELL and R. H. CLARK (Trans. Roy. Soc. Canada, 1935, [iii], 29, III, 61–68).—Quant. comparison of the prep. of unsaturated hydrocarbons from 25 halides by the use of  $\text{EtOH-KOH}$  (I), quinoline (II),  $\text{NH}_2\text{Ph}$ ,  $\text{NPhMe}_2$ ,  $\text{NPhEt}_2$ ,  $\text{C}_5\text{H}_5\text{N}$ , and piperidine indicates that (I) gives poor yields with *n*-halides owing to formation of ethers, but, together with the org. bases, is suitable for higher *sec.*, *tert.*, and *cyclo*-halides, whilst (II) is recommended for *n*- and lower *sec.*-halides. Bromides and iodides give better yields than chlorides. F. O. H.

Allylic rearrangements. II. Magnesium crotyl and methylvinylcarbinyl bromides. W. G. YOUNG, S. WINSTEIN, and A. N. PRATER (J. Amer. Chem. Soc., 1936, 58, 289–291; cf. A., 1932, 250).—The same mixture (method of analysis: Dillon *et al.*, A., 1930, 888) of  $56.4 \pm 2\%$  of  $\Delta^a$ - and  $26.5 \pm 1.4\%$  *cis*- and  $17.2 \pm 3\%$  *trans*- $\Delta^a$ -butene is obtained by hydrolysis (dil. HCl) of the Grignard reagents (A) from various mixtures of  $\text{CHMe}^\bullet\text{CH}^\bullet\text{CH}_2\text{Br}$  and  $\text{CH}_2^\bullet\text{CH}^\bullet\text{CHMeBr}$ . Rearrangement occurs during the formation of (A). H. B.

Thermal rearrangements of pentenes. C. D. HURD, G. H. GOODYEAR, and A. R. GOLDSBY (J. Amer. Chem. Soc., 1936, 58, 235–237).— $\Delta^a$ -Pentene (I) undergoes 56–58% decomp. at 580–600° (contact time 13–18 sec.; method essentially that of A., 1934, 1089) to give liquid (probably mainly *cycloalkenes* and aromatic hydrocarbons) and gaseous products ( $\text{CH}_4$ ,  $\text{C}_2\text{H}_6$ ,  $\text{C}_2\text{H}_4$ ,  $\text{C}_3\text{H}_6$ , and  $\Delta^a$ -butene in the mol. ratio 6:2:1:2:2; small amounts of  $\text{H}_2$ ,  $\text{C}_3\text{H}_8$ ,  $\Delta^a$ -butene, and butadiene). A little of (I) rearranges to  $\Delta^b$ -pentene (II). The extent of decomp. of (II) at 580° and 600° is 23 and 54%, respectively. Essentially the same products are formed and a little of the (II) rearranges to (I). (I) prepared from  $\text{MgEtBr}$  and allyl bromide in  $\text{Bu}_2\text{O}$  contains a little  $\text{CH}_3^\bullet\text{CHPr}^\bullet$  (removable by distillation) [the statement (B., 1934, 228) that this is produced during pyrolysis of (I) is erroneous]. (II) (free from isomerides) is obtained by dehydration ( $\text{H}_2\text{SO}_4$ ) of  $\text{CHEt}_2\text{OH}$ . H. B.

Dimerisation of divinyl. J. M. SLOBODIN (J. Gen. Chem. Russ., 1935, 5, 1415–1420).—The condensate obtained as a by-product of the catalytic prep. of divinyl from  $\text{EtOH}$  by Lebedev's method consists of *p*-xylene 66, and 4-vinyl- $\Delta^1$ -cyclohexene +  $\text{PhMe} + \text{PhEt}$  33%; the probable intermediates are  $\text{CH}_2^\bullet\text{CH}^\bullet\text{CHMe}^\bullet\text{CH}^\bullet\text{CH}^\bullet\text{CH}_2^\bullet$ ,

$\text{CHMe}^\bullet\text{CH}^\bullet\text{CH}^\bullet\text{CH}^\bullet\text{CH}^\bullet\text{CHMe}^\bullet$ , and

$\text{CHMe}^\bullet\text{CH}^\bullet\text{CH}_2^\bullet\text{CH}_2^\bullet\text{CH}^\bullet\text{CH}_2^\bullet\text{CH}_2^\bullet\text{CH}^\bullet\text{CHMe}^\bullet$ . R. T.

Rôle of intermediate compounds in the process of catalytic polymerisation of acetylene. I. Reaction of acetylene with solutions of cuprous and ammonium chlorides, and a study of the complexes formed. L. G. TZIURICH and A. A. GINZBURG (J. Gen. Chem. Russ., 1935, 5, 1468–1478).—The cryst. product obtained by saturating a solution containing  $\text{CuCl}$  18 and  $\text{NH}_4\text{Cl}$  20% with  $\text{C}_2\text{H}_2$  has the composition  $6\text{CuCl}_3\text{NH}_4\text{Cl}_2\text{C}_2\text{H}_2$ ; it readily dissociates into its components, with which it is in equilibrium in the solution. R. T.

Hydrogenation of vinylacetylene. S. V. LEBEDEV, A. I. GULJAEVA, and A. A. VASSILIEV (J. Gen. Chem. Russ., 1935, 5, 1421–1433).—The  $\text{C}^\bullet\text{C}^\bullet$  and  $\text{C}^\bullet\text{C}^\bullet\text{C}^\bullet$  groups of  $\text{CH}_2^\bullet\text{CH}^\bullet\text{C}^\bullet\text{CH}$  (I) are hydrogenated simultaneously and with equal velocity in presence of Pt catalyst, whilst with Pd (on Ni or Na prot-albinate) addition takes place chiefly at the triple linking;  $\text{CHMe}^\bullet\text{CHMe}^\bullet$  is not found amongst the products of incomplete hydrogenation. (I) may be

quantitatively reduced to divinyl by nascent H (from Zn-Cu and H<sub>2</sub>O, or at a Pt-black cathode). R. T.

**Action of anhydrous alkaline earths on monohalogenated paraffins.** J. B. SENDERENS and J. ABOULENC (Compt. rend., 1936, 202, 104—106).—When dropped on heated CaO or BaO (reaction temp. in parentheses) C<sub>n</sub>H<sub>2n+1</sub>Cl decomposes cleanly to C<sub>n</sub>H<sub>2n</sub>+HCl (retained by catalyst). Thus Bu<sup>n</sup>Cl (275—285°) or Bu<sup>n</sup>Br (300—310°) gives C<sub>4</sub>H<sub>8</sub>; Pr<sup>n</sup>Cl (250°) or Pr<sup>n</sup>Br (265°) gives CHMe:CH<sub>2</sub>, and Bu<sup>n</sup>Cl (210°) gives CMe<sub>2</sub>:CH<sub>2</sub>. No C is deposited.

J. W. B.

**From iodoform to fluoroform.** O. RUFF [with O. BRETSCHNEIDER, W. LUCHSINGER, and G. MILTSCHUTZKY] (Ber., 1936, 69, [B], 299—308).—CHF<sub>3</sub> obtained by heating CHI<sub>3</sub>-AgF-SiO<sub>2</sub> is contaminated with CO and considerable amounts of SiF<sub>4</sub>. CaF<sub>2</sub> is a more suitable diluent, the best results being secured with AgF:CaF<sub>2</sub>=1:4 and HgF:CaF<sub>2</sub>=1:1.2. The prep. of CHF<sub>3</sub>, CHIF<sub>2</sub>, and CHI<sub>2</sub>F from HgF, CHI<sub>3</sub>, and CaF<sub>2</sub> (33.4:20:40) is described in detail. At >100° PbF<sub>2</sub>, ZnF<sub>2</sub>, CuF<sub>2</sub>, CoF<sub>2</sub>, and SbF<sub>3</sub> do not yield appreciable quantities of CHF<sub>3</sub>. Slow passage of CHCl<sub>3</sub> vapour over AgF-CaF<sub>2</sub> gives about 57% of CHCl<sub>2</sub>F at 100° and about 48% of CHClF<sub>2</sub> at 250°; at 340° about 10% of CHF<sub>3</sub> is obtained, but the mixture sinters and becomes ineffective at this temp. At about 500° PbF<sub>2</sub> gives a little CHCl<sub>2</sub>F among other products. CHF<sub>3</sub> has b.p. -84.4°/760 mm., m.p. -160°. It does not lose HF when heated alone or in presence of KF at 1150°. It is unchanged by HNO<sub>3</sub> alone or with conc. H<sub>2</sub>SO<sub>4</sub>, N<sub>2</sub>O<sub>3</sub>, or AgNO<sub>3</sub> at 140°; at >175° it is completely decomposed by N<sub>2</sub>O<sub>3</sub>. NOF leaves it partly unchanged after 3 hr. at 100° and Mn<sub>2</sub>O<sub>7</sub> is without action at 25°. Oxidising agents transform it into COF<sub>2</sub> and HF. It is unaffected by CaO at 365°. Iododifluoromethane, b.p. 21.6°/760 mm., is very sensitive to light and air, but in their absence it is stable indefinitely. It is only partly decomposed by Pt-asbestos at 700°. It reacts readily with AgNO<sub>3</sub>. Di-iododifluoromethane, b.p. 100.3±0.5°/760 mm., m.p. -34.5°±0.5°, is sensitive to light and air. It slowly separates I when warmed; at >250° it is almost completely decomposed with production of HF. It reacts with Mg only when irradiated. With liquid NH<sub>3</sub> it gives NH<sub>4</sub>F and NH<sub>4</sub>I. With Na<sub>2</sub>SO<sub>3</sub> in 50% EtOH at 80° complete separation of F from C is observed.

H. W.

**Hydrolysis of isopropyl bromide.**—See this vol., 433.

**Alcohol determination.** R. M. MAYER (Deut. Z. ges. gerichtl. Med., 18, 638—646; Chem. Zentr., 1935, i, 3961).—A modified Nicloux method is described.

H. N. R.

**Alcoholic fermentation in heavy water.**—See this vol., 522.

**Determination of small concentrations. II. Butyl and amyl alcohols.** M. V. ALEXEEVA (J. Gen. Chem. Russ., 1935, 5, 1324—1330).—7 ml. of 0.05N-KMnO<sub>4</sub> and 10 ml. of 5N-H<sub>2</sub>SO<sub>4</sub> are added to 10 ml. of solution, containing 0.1—1.5 mg. of BuOH or C<sub>5</sub>H<sub>11</sub>·OH, the mixture is kept in the dark for

35 min., when 10 ml. of 0.05N-Na<sub>2</sub>C<sub>2</sub>O<sub>4</sub> are added, the solution is warmed to 80—90°, and excess of oxalate is titrated with 0.05N-KMnO<sub>4</sub>. Esters to an amount of >25% of that of the alcohols present do not interfere, but EtOH should be absent.

R. T.

**Mechanism of conversion of Δ<sup>γ</sup>-butenol into Δ<sup>β</sup>-butenyl bromide.** L. W. J. NEWMAN and H. N. RYDON (J.C.S., 1936, 261—264).—Δ<sup>β</sup>- (I) and Δ<sup>γ</sup>-Butenol (II) are stable to boiling alone, hot 30% KOH, Ac<sub>2</sub>O, and AcOH; Δ<sup>β</sup>- (III) and Δ<sup>γ</sup>-butenyl bromides are similarly stable and hydrolysis of the acetates does not cause isomerisation. Change of (II) into (III) by hot H<sub>2</sub>SO<sub>4</sub>-HBr occurs by dehydration to butadiene and addition of HBr thereto, both the last reactions having been separately realised under the experimental conditions used. CH<sub>2</sub>:CMe·CH<sub>2</sub>·OH reacts with HBr as does (I) and its bromide is hydrolysed at the same rate as is (III). Mixtures of the Δ<sup>β</sup>- and Δ<sup>γ</sup>-isomerides are analysed by the much more rapid esterification by HBr or hydrolysis of the Δ<sup>β</sup>-isomeride at room temp.

R. S. C.

**Action of micro-organisms on the diastereomeric forms of hexane-γδ-diol.** H. VAN RISSEHEM (Bull. Soc. chim. Belg., 1936, 45, 21—35).—Griner's mixed [CH<sub>2</sub>:CH·CH(OH)·]<sub>2</sub> with H<sub>2</sub>-Pd-black in Et<sub>2</sub>O gives meso- (I), m.p. 90.1—90.2°, b.p. 115.1°/24 mm., and dl-hexane-γδ-diol (II), f.p. 20.9°, b.p. 108.65—108.75°/24 mm. (I) with *B. xylinum* or *M. aceti* gives d-hexan-γ-one-8-ol (III), b.p. 70.7—71°/22 mm., [α]<sub>D</sub><sup>20</sup> +88.16°, and a little (EtCO)<sub>2</sub> (II) with *B. xylinum* slowly or *M. aceti* rapidly gives the l-form of (III), whilst some l-(II) remains unattacked; d-(II) thus reacts preferentially. It is concluded that bacteria attack the d-C. Hydrogenation of d-(III) gives l-(II), b.p. 105.7—106.2°/20 mm., [α]<sub>D</sub><sup>20</sup> -12.24°.

R. S. C.

**Lycoxanthine and lycophyll, two natural derivatives of lycopene.** L. ZECHMEISTER and L. von CHOLNOKY (Ber., 1936, 69, [B], 422—429).—The fruits of *Solanum dulcamara* are ground with sand, washed with EtOH, and then extracted with Et<sub>2</sub>O. After removal of the solvent the residue is dissolved in C<sub>6</sub>H<sub>6</sub> and analysed chromatographically using Ca(OH)<sub>2</sub>. Alternatively, the dry residue is dissolved in benzene and the solution shaken with 90% MeOH; the final treatment is with Ca(OH)<sub>2</sub> in C<sub>6</sub>H<sub>6</sub>-benzene. Thus are obtained lycoxanthine (I), m.p. 168° (corr.) (acetate, m.p. 137°), lycophyll (II), C<sub>40</sub>H<sub>56</sub>O<sub>2</sub>, m.p. 179° (corr.) [dipalmitate, m.p. 76° (corr.)], and lycopene (III). The absorption spectra of (I), (II), and (III) are so remarkably similar that the presence of 11 conjugated and two isolated double linkings in each is regarded as established. On the assumption that the OH occupy the same positions as in other xanthophylls, the constitution

CMe<sub>2</sub>·CH·CH(OH)·CH<sub>2</sub>·[CMe·CH·CH:CH]<sub>3</sub>·[CH:CMe·CH:CH]<sub>2</sub>·CH:CH·CMe·CH<sub>2</sub>·CHR·CH:CMe<sub>2</sub> is assigned with R=H in (I) and R=OH in (II). The quant. separation of (II) from (I) and (III) is described, also the determination of (I) and (II) in the crude materials. (I) and (II) do not appear to be present in preserved tomatoes, but are detected in the

fresh fruit. The berries of *Tamus communis* contain (III) a little (I), but not (II). The carotenoids are unesterified. (I) and (II) are absent from *Rosa canina*, but present in traces in *Actinophleus Macarthurii*. (III) and its derivatives are not contained in *Coloneaster horizontalis*.  
H. W.

$\alpha$ -D-[ $\gamma$ -]Anhydromannitol. F. VALENTIN (Coll. Czech. Chem. Comm., 1936, 8, 35—42).— $\alpha$ -Methylmannopyranoside 6-bromide (freed from  $\text{NH}_2\text{Ac}$  by  $\text{EtOAc}$ ) with  $\text{Ba}(\text{OH})_2$  gives  $\alpha$ -methyl- $\gamma$ -anhydromannopyranoside, stable to  $\text{H}_2\text{S}$ , hydrolysed by 3%  $\text{HCl}$  to  $\gamma$ -anhydromannofuranose (I), which with 2.5%  $\text{Na-Hg}$  in slightly alkaline solution gives  $\alpha$ -anhydromannitol (50% yield), m.p.  $148^\circ$  (lit.  $138^\circ$ ),  $[\alpha]_D^{20} -23.75^\circ$  in  $\text{H}_2\text{O}$  (dibenzylidene derivative, m.p.  $125-126^\circ$ ,  $[\alpha]_D^{20} -48.8^\circ$  in  $\text{CHCl}_3$ ), which with  $\text{Br}$  reverts to (I).  $\text{CHPh}$  is determined by distillation with 60%  $\text{H}_2\text{SO}_4$  in  $\text{CO}_2$  and determination of the  $\text{PhCHO}$  in the distillate as phenylhydrazone.  
R. S. C.

Chloroalkoxylation of olefines by the action of chlorine in presence of alcoholic alkali. M. V. LICHOSCHERSTOV and A. A. PETROV (J. Gen. Chem. Russ., 1935, 5, 1348—1354).—Compounds of the type  $\text{OR}\cdot\text{CHMe}\cdot\text{CHMeCl}$  (I) ( $\text{R}=\text{alkyl}$ ) are obtained in 60—70% yield by adding a 30% excess of  $\text{NaOH}$  to the  $\text{ROH}$ , passing  $\text{Cl}_2$  continuously (25% excess), and introducing  $\text{CHMe}\cdot\text{CHMe}$  intermittently. When the mixture is diluted with  $\text{H}_2\text{O}$ , a 3:1 mixture of (I) and  $(\cdot\text{CHMeCl})_2$  separates.  
R. T.

Preparation of dimethylacetal by condensing methyl alcohol with acetylene. S. TAMARU and Y. TANAKA (J. Chem. Soc. Japan, 1935, 56, 486—504).— $\text{HgCl}_2$  or  $\text{H}_2\text{SO}_4$  may be used as catalysts, the optimum temp. being  $40^\circ$ ; the former is prevented from losing its activity by addition of  $\text{Fe}_2(\text{SO}_4)_3$ .  
CH. ABS. (r)

Mixed glycerides of salicylic acid and fatty acids. A. LUKASIAK (Rocz. Farm., 1934, 12, 1—26; Chem. Zentr., 1935, i, 3005—3006).—Resorption of salicylic acid (I) compounds is followed by determination of (I) in the urine. Results with  $\text{Et}$  and ethylene salicylates, the triglyceride of (I), salicylodichlorohydrin, and  $\alpha$ -distearo- $\beta$ -salicylin are described. The following are described:  $\beta$ -palmito-, m.p.  $32^\circ$ ,  $\beta$ -butyro-, b.p.  $102-103^\circ/12\text{ mm.}$ , and  $\beta$ -isovalero-, b.p.  $104-106^\circ/8\text{ mm.}$ , - $\alpha\gamma$ -dichlorohydrin;  $\alpha\beta$ -dibutyro- $\gamma$ -monochlorohydrin, b.p.  $133-136^\circ/8\text{ mm.}$ ; diisovalero- $\alpha$ -iodohydrin, b.p.  $153-155^\circ/4\text{ mm.}$ ;  $\alpha\gamma$ -diisovalerin, b.p.  $146-150^\circ/5\text{ mm.}$ ;  $\alpha\alpha$ -diisovalero- $\beta$ -salicylin, b.p.  $210-212^\circ/4\text{ mm.}$ ;  $\alpha$ -salicylo- $\gamma\gamma$ -dibutyryn, b.p.  $198-201^\circ/3\text{ mm.}$ ;  $\beta$ -palmito-, m.p.  $44^\circ$ ,  $\beta$ -butyro-, m.p.  $51^\circ$ , and  $\beta$ -isovalero- $\alpha\gamma$ -disalicylin, m.p.  $65^\circ$ .  
H. N. R.

Spectrophotometric determination of ethylene glycol dinitrate. J. H. FOULGER (J. Ind. Hyg., 1936, 18, 127—129).—The absorption of the coloured solution, formed by the action of  $\text{OH}\cdot\text{C}_6\text{H}_5(\text{SO}_3\text{H})_2$  on  $\text{C}_2\text{H}_4(\text{O}\cdot\text{NO}_2)_2$  (I), at  $4900\text{ \AA.}$  has been determined, and data obtained by which the concn. of (I) can be determined from (a) the sp. extinction val. (for concn.  $1.6-3.3\text{ mg. per }100\text{ c.c.}$ ) and (b) a table of differences of photometer readings (for concn.  $0.5-4.2\text{ mg. per }100\text{ c.c.}$ ).  
J. N. A.

Interpretation of differences in properties of alkyl chlorosulphites and chloroformates from the electronic viewpoint. P. CARRÉ (Compt. rend., 1936, 202, 298—300; cf. A., 1935, 606).—A discussion.

Reaction of complex sulphuric acid esters. L. LISON (Bull. Soc. Chim. biol., 1936, 18, 225—230).—The colour change produced by org. esters of  $\text{H}_2\text{SO}_4$  of high mol. wt. on metachromatic dyes such as toluidine-blue and cresyl-blue is sp. for such substances and might be used in their qual. investigation.  
A. L.

Polysaccharide hydrogen sulphates with heparin-like action. S. BERGSTRÖM (Z. physiol. Chem., 1936, 238, 163—168; cf. A., 1935, 1519).—Details are given of the prep. and activities of the esters [including that from pectic acid (I)]. Synthetic chondroitintrisulphuric acid, chitindisulphuric acid, and (I) polysulphate have activities  $\leftarrow$  that of the product (II) from cellulose. The activities of the other preps. are only 8—50% of that of (II).  
W. McC.

Mannitoldimolybdic acid. Variation of the  $p_H$  of molybdic acid caused by addition of sugar. (MME.) Z. SOUBAREV-CHATELAIN (Compt. rend., 1935, 201, 1390—1392).—The effect of sugars, e.g., mannitol, on the  $p_H$  of molybdic acid and its salts (A., 1933, 909) is explained by formation of mannitoldimolybdic acid (I),  $[\text{C}_6\text{H}_{14}\text{O}_6\cdot\text{HMo}_2\text{O}_7]\text{H}$ , thus: increase of  $p_H$ ,  $2\text{Na}_2\text{MoO}_4 + \text{C}_6\text{H}_{14}\text{O}_6 + 2\text{H}_2\text{O} \rightleftharpoons (\text{I}) + 3\text{NaOH}$ ; decrease of  $p_H$ ,  $2[\text{MoO}_3\text{Cl}_2]\text{H}_2 + \text{C}_6\text{H}_{14}\text{O}_6 + \text{H}_2\text{O} \rightleftharpoons (\text{I}) + 4\text{HCl}$ .  
R. S. C.

Aminoethyl phosphate from tumours.—See this vol., 364.

Specific reaction of dichlorodiethyl sulphide in presence of other chemical warfare gases. M. OBERMILLER (Angew. Chem., 1936, 49, 162—164).— $\text{S}(\text{CH}_2\cdot\text{CH}_2\text{Cl})_2$  (I) in small concn. gives with aq. solutions of  $\text{AuCl}_3$  and  $\text{PdCl}_2$  a strong yellow colloidal turbidity. On filter-paper reddish-brown and yellow stains are given with  $\text{AuCl}_3$  and  $\text{PdCl}_2$ , respectively. Negative results were obtained with the other common war gases. A positive result was observed with 1.5 mg. of (I) in 20 c.c. of liquid. By means of a special apparatus (I) could be removed from a large vol. of air and (I) in concn. of 10 mg. per cu. m. detected in 4 min.  
D. C. J.

Mechanism of the sulphonation process. A. MICHAEL and N. WEINER (J. Amer. Chem. Soc., 1936, 58, 294—299).—Contrary to Wieland (cf. A., 1920, i, 280), the reaction between  $\text{C}_2\text{H}_4$  and oleum (I) does not involve addition of  $\text{H}_2\text{SO}_4$  (as  $\text{OH}+\text{SO}_3\text{H}$ ). The results now obtained [and the data of Plant and Sidgwick (A., 1921, i, 153)] show that  $\text{H}_2\text{S}_2\text{O}_7$  is the reactive entity and leads to ethionic acid (II) [ $\text{Ba}$  salt (+0.5 $\text{H}_2\text{O}$ )]; each mol. of  $\text{H}_2\text{S}_2\text{O}_7$  gives 1 mol. of (II):  $\text{CH}_2\cdot\text{CH}_2 + \text{OH}\cdot\text{SO}_2\cdot\text{O}\cdot\text{SO}_2\cdot\text{OH} \rightarrow \text{SO}_3\text{H}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{O}\cdot\text{SO}_3\text{H}$ . When (I) contains more  $\text{SO}_3$  than is necessary to form  $\text{H}_2\text{S}_2\text{O}_7$ , carbyl sulphate (III),  $\text{SO}_2\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{O}\cdot\text{SO}_2$ , is also formed by the direct addition of  $\text{S}_2\text{O}_6$  to  $\text{C}_2\text{H}_4$ . (III) is also produced from  $\text{C}_2\text{H}_4$  (excess) and  $\text{SO}_3$  in the gaseous phase ( $\text{CO}_2$  used as diluent). Isethionic acid,  $\text{OH}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{SO}_3\text{H}$ , is

converted into (II) by (a) 100%  $\text{H}_2\text{SO}_4$  (1 mol.), (b) 100%  $\text{H}_2\text{SO}_4$  (1 mol.) followed by  $\text{SO}_3$  (1 mol.), and (c)  $\text{SO}_3$  (1 mol.); 2 mols. of  $\text{SO}_3$  give (III).

Wieland's mechanism (*loc. cit.*) of aromatic substitution is held to be untenable. Sulphonation is considered to be an aldolisation (pseudo-substitution) reaction (cf. A., 1935, 1103). The formation of  $\text{Ph}_2\text{SO}_2$  from  $\text{C}_6\text{H}_6$  and (I) is explained:  $2\text{C}_6\text{H}_6 + \text{S}_2\text{O}_6 \rightarrow \text{SO}_2 \begin{smallmatrix} \diagup \text{O} \diagdown \\ \diagdown \text{O} \diagup \end{smallmatrix} \text{SPh}_2(\text{OH})_2 \rightarrow \text{Ph}_2\text{SO}_2 + \text{H}_2\text{SO}_4$ .

$\text{C}_6\text{H}_6$  could not be sulphonated by  $\text{Me}_2\text{SO}_4 + \text{AlCl}_3$ ; methylation occurs owing to the production of  $\text{MeCl}$ .

H. B.

[Addition of bromine to] unsaturated acids. C. E. SUN (J. Chinese Chem. Soc., 1936, 4, 1—5).—The activation energy for the addition of Br to  $\beta\gamma$ -unsaturated acids is probably the same as for olefines (22.4 kg.-cal.), whilst that for  $\alpha\beta$ -unsaturated acids is calc. to be 31.5 kg.-cal., in agreement with the more facile reaction in the former case.

R. S. C.

Exchange between organic compounds and heavy water. F. K. MÜNDBERG [with W. OBERST] (Z. physikal. Chem., 1935, B, 31, 18—22).—There is a small exchange of H for D in a solution of  $\text{HCO}_2\text{Na}$  in heavy  $\text{H}_2\text{O}$  at  $100^\circ$ , but not below. With solutions of  $\text{HCO}_2\text{H}$ ,  $\text{CO}_2\text{H} \cdot [\text{CH}_2]_2 \cdot \text{CO}_2\text{H}$ , and  $\text{CH}_2\text{Cl} \cdot \text{CO}_2\text{H}$  at  $50^\circ$  only the H of  $\text{CO}_2\text{H}$  is exchangeable, whilst with  $\text{CH}_2(\text{CO}_2\text{H})_2$  all the H may be exchanged.

R. C.

Thermal decomposition of esters in presence of aluminium chloride. H. GAULT and E. BELOFF (Compt. rend., 1936, 202, 71—73).— $\text{Bu}^n\text{OAc}$  heated with  $\text{AlCl}_3$  to  $300$ – $330^\circ$  gives  $\text{Bu}^n\text{Cl}$  (50—55%), olefine (liquid at  $-70^\circ$ ), and a mixture of  $\text{CO}$ ,  $\text{CO}_2$ ,  $\text{H}_2$ , and  $\text{CH}_4$  with traces of  $\text{C}_2\text{H}_6$ ,  $\text{C}_3\text{H}_8$ , and olefine. The amount of  $\text{BuOAc}$  decomposed  $\propto$  the wt. of  $\text{AlCl}_3$  used. Rise of temp. gives more gaseous products, but does not otherwise alter the course of the decomp.

H. B.

Electrolytic reduction of organic compounds. I. Analogies between cathodic reduction and the action of dissolving metals. Reduction of sorbic acid. E. ISAACS and C. L. WILSON (J.C.S., 1936, 202—207).—Evidence is reviewed showing that the course of electrolytic reduction depends on the solvent used.  $\text{H}_2$  overvoltage is important for reduction of ketones and aldehydes, but not for sorbic acid (I). Reduction of (I) gives the following % of  $\Delta^7$ -hexenoic acid in the product at Hg, Cd, and Cu cathodes: in  $N$ -NaOH, 40, 39, and 40; in 0.5*N*- $\text{NaHCO}_3$ , 41, —, —; in 70%  $\text{AcOH} + 0.5M$ - $\text{NaOAc}$ , 54, 50, and 50; in 2*N*- $\text{H}_2\text{SO}_4$ , 52, —, —, respectively; these are very similar to the results obtained with Na-Hg and Al-Hg (A., 1929, 1270). Hg as cathode or amalgam leads to much "pinacol," b.p.  $180$ – $183^\circ / <1$  mm. Anthracene gives the 9:10- $\text{H}_2$ -derivative with Na-Hg, Al-Hg, or Mg-Hg in EtOH or, better, dioxan, or at a Hg cathode in alcoholic NaOH,  $(\text{NH}_4)_2\text{SO}_4 + \text{NH}_3$ , or  $\text{NMe}_4\text{OH}$ .

R. S. C.

Tricosanoic and tetracosanoic acids and their derivatives. R. ASHTON, R. ROBINSON, and J. C. SMITH (J.C.S., 1936, 283—285).—Lauryl chloride, b.p.  $134^\circ / 9$ –10 mm., is condensed with  $\text{CH}_3\text{Ac} \cdot \text{CO}_2\text{Et}$  and Na, and the product treated with Et  $\lambda$ -bromo-

undecolate, b.p.  $174^\circ / 10$  mm.; hydrolysis then leads to *v*-ketotetracosanoic acid, m.p.  $95^\circ$ , reduced (Clemmensen) to tetracosanoic acid (I), m.p. (a)  $83.5$ – $84.5^\circ$  (capillary), (b)  $83.8^\circ$  (thermometer in melt), f.p.  $83.5^\circ$ . Br yields  $\alpha$ -bromotetracosanoic acid, m.p.  $71.5$ – $72^\circ$  (lit.  $69.5$ – $70^\circ$ ), and thence is obtained  $\alpha$ -hydroxy-tetracosanoic acid, m.p.  $99.5$ – $100^\circ$  (lit.  $94$ – $95^\circ$ ). Undecoyl chloride leads similarly to tricosanoic acid (II), m.p. (a)  $79$ – $80.5^\circ$ , (b)  $78.86^\circ$ , f.p.  $78.75^\circ$ . (I) and (II) give continuous solid solutions with a max. depression of the m.p. of  $0.45^\circ$ . The product of oxidation of cerebronic acid may be impure (I).

R. S. C.

Preparation of unsaturated acids from stearic acid. E. M. PRIK (Plast. Massui, 1934, No. 6, 26—27).—Chlorination of stearic acid, followed by elimination of HCl (Zn dust, or heating in vac.), yields an unsaturated product, b.p.  $190$ – $214^\circ / 5$  mm.

CH. ABS. (r)

Reactions in monolayers of drying oils. I, II. —See this vol., 434.

Qualitative test for linolenic acid, its value and limitations. G. J. MARTIN (J. Amer. Chem. Soc., 1936, 58, 364—365).—Oils containing linolenic acid (I) give a deep blue colour when 1 c.c. is heated with 5 c.c. of arsenophosphotungstic acid (Benedict, A., 1931, 973) at  $100^\circ / 1$  hr. Approx. determinations of the amount of (I) present can be made; Me linolenate is used as standard. Other fatty acids containing 3 double linkings give the reaction.

H. B.

Fatty acids of phrenosin and kersin. A. C. CHIBNALL, S. H. PIPER, and E. F. WILLIAMS (Biochem. J., 1936, 30, 100—114).—Brain contains at least 3 phrenosins and 3 kersins, the components of which differ only in the chain-length of the fatty acids. A sample of phrenosinic (cerebronic) acid (I), m.p.  $102.3$ – $102.6^\circ$ ,  $[\alpha]_D^{25} + 3.33^\circ$  in  $\text{C}_5\text{H}_5\text{N}$  (Ac derivative, m.p.  $66$ – $66.5^\circ$ ), obtained by hydrolysis of a highly purified specimen of phrenosin is shown to consist of a mixture of even-no.  $\alpha$ -OH-acids of mean mol. wt. corresponding closely with  $\text{C}_{24}$ , which on oxidation with  $\text{CrO}_3$  in  $\text{AcOH}$  give a mixture of odd-no. *n*-fatty acids, identified as 85%  $\text{C}_{23}$  and 15%  $\text{C}_{25}$ . (I) consists therefore of 85% of  $\alpha$ -hydroxy-*n*-tetracosanoic and 15% of  $\alpha$ -hydroxy-*n*-hexacosanoic acids. (I) of low m.p. contains also  $\alpha$ -hydroxy-*n*-docosanoic acid. Thudichum's neurostearic acid probably consists of 25—30% of (I), the rest being "lignoceric acid" (II). The acidic constituents of the kersins are *n*-docosanoic, *n*-tetracosanoic, and *n*-hexacosanoic acids; (II) is thus also a mixture and the name should be abandoned. Several binary mixtures of *n*-fatty acids of chain-length from  $\text{C}_{21}$  to  $\text{C}_{25}$  have been prepared and their m.p. and crystal spacings recorded.

P. W. C.

Absolute configuration of lactic acid. Assumptions made in calculation of optical rotation. W. KUHN (Z. physikal. Chem., 1935, B, 31, 23—57).—The sign of the rotation of  $\text{CHMcEt} \cdot \text{OH}$  has been calc. by means of a simplified model in which the Me, Et, and active C are each replaced by an isotropic resonator with the charge of the Et group > that at the centre of the Me or active C; the resonance interaction between the three, taken as having the

same natural frequency, is calc. by an exact method. If the optical vibration of the OH absorption band of longest  $\lambda$  is assumed to be non-isotropic the model will be optically active, whilst if the OH group is isotropic there will be no activity. From the light scattering and Kerr effects of OH-compounds it is probable that for the COH group the above absorption band vibrates in the plane defined by the C, O, and

H atom. This leads to  $\text{H}-\overset{\text{CO}_2\text{H}}{\underset{\text{Me}}{\text{C}}}-\text{OH}$  where the Me and

$\text{CO}_2\text{H}$  lie behind the plane of the paper, for the configuration of  $d(-)$ -lactic acid. Calculation shows that for  $\text{CHRR}'\text{OH}$  the direction of rotation is independent of the sp. nature of R and R'. On both theoretical and experimental grounds vibrations corresponding with optical absorption bands of a mol. must be regarded as non-isotropic. The direction of the optical vibrations of the absorption band of longest  $\lambda$  of a given mol. generally is that in which the polarisability, as measured by the Kerr effect and light scattering, is a max. In the most important cases optical activity appears to be an effect not of the third, but of the first, or at most second, order.

R. C.

**Mechanism of reactions of metal enolates of acetoacetic ester and related compounds. III. Copper enolates.** A. MICHAEL and G. H. CARLSON (J. Amer. Chem. Soc., 1936, 58, 353—364; cf. A., 1935, 474).—The  $\text{Cu}^{\text{II}}$  enolate (I) (1 mol.) of  $\text{CH}_2\text{Ac}\cdot\text{CO}_2\text{Et}$  and Cl (1.5 mols.) in  $\text{CCl}_4$  at  $0^\circ$  or the b.p. give  $\text{Cu}_2\text{Cl}_2$  (1 mol.) and  $\text{CHClAc}\cdot\text{CO}_2\text{Et}$  (II) (2 mols.); the formation of  $\text{CuCl}_2$  (Schönbrodt, A., 1890, 27) is ascribed to the use of an excess of Cl. (I) and  $\text{Cu}_2\text{Cl}_2$  are also formed from (I) and  $\text{CuCl}_2$  in boiling  $\text{C}_6\text{H}_6$ . (I) and  $\text{AcCl}$  (1.5 mols.) in  $\text{C}_6\text{H}_6$  or  $\text{Et}_2\text{O}$  at room temp. afford  $\text{Cu}_2\text{Cl}_2$ , (II), and  $\text{OAc}\cdot\text{CMe}\cdot\text{CH}\cdot\text{CO}_2\text{Et}$ ;  $\text{CHAc}_2\cdot\text{CO}_2\text{Et}$  (III) is not formed. The  $\text{Cu}^{\text{II}}$  enolate (IV) of (III) with  $\text{AcCl}$  similarly gives the *O*-Ac derivative of (III) and the (impure) enolate,  $\text{ClCu}\cdot\text{O}\cdot\text{CMe}\cdot\text{CAc}\cdot\text{CO}_2\text{Et}$ , which is converted by cold  $\text{H}_2\text{O}$  into (IV) and by  $\text{AcCl}$  in boiling  $\text{C}_6\text{H}_6$  into (III),  $\text{CuCl}_2$ , and  $\text{Cu}_2\text{Cl}_2$ . The  $\text{Cu}^{\text{II}}$  enolate (V) of  $\text{CH}_2\text{Bz}\cdot\text{CO}_2\text{Et}$  (VI) and  $\text{AcCl}$  (2 equivs.) in boiling  $\text{C}_6\text{H}_6$  afford the *O*-Ac derivative of (VI),  $\text{CuCl}_2$ , and some  $\text{Cu}_2\text{Cl}_2$ ; reaction is slow at room temp. and an intermediate enolate cannot be isolated. (I) and  $\text{ClCO}_2\text{Et}$  (2 equivs.) in boiling  $\text{C}_6\text{H}_6$  give (cf. Nef, A., 1892, 140)  $\text{Cu}_2\text{Cl}_2$ , some  $\text{CHAc}(\text{CO}_2\text{Et})_2$ , the enolate,  $\text{ClCu}\cdot\text{O}\cdot\text{CMe}\cdot\text{C}(\text{CO}_2\text{Et})_2$ , and unidentified products; (V) and  $\text{ClCO}_2\text{Et}$  (1.5 mols.) similarly yield  $\text{Cu}_2\text{Cl}_2$ ,  $\text{CHBz}(\text{CO}_2\text{Et})_2$ , and a little of the enolate,  $\text{ClCu}\cdot\text{O}\cdot\text{CPh}\cdot\text{C}(\text{CO}_2\text{Et})_2$ . (I) and  $\text{BzCl}$  in boiling  $\text{C}_6\text{H}_6$  afford (cf. Nef, A., 1893, i, 628)  $\text{Cu}_2\text{Cl}_2$ , (VIII) (below),  $\text{CHBzAc}\cdot\text{CO}_2\text{Et}$ ,  $\text{CBz}_2\text{Ac}\cdot\text{CO}_2\text{Et}$ , and  $\text{OBz}\cdot\text{CMe}\cdot\text{CH}\cdot\text{CO}_2\text{Et}$  (VII), b.p.  $139^\circ/1.5$  mm., m.p.  $42^\circ$ , in varying proportions (according to amount of  $\text{BzCl}$  used). (I) and dry  $\text{HCl}$  (1 equiv.) in  $\text{Et}_2\text{O}$  and  $\text{N}_2$  furnish the unstable, impure enolate,  $\text{ClCu}\cdot\text{O}\cdot\text{CMe}\cdot\text{CH}\cdot\text{CO}_2\text{Et}$  [which is probably an intermediate in the reaction between (I) and  $\text{AcCl}$ ], converted by cold  $\text{H}_2\text{O}$  into (I) and  $\text{CuCl}_2$ , and by  $\text{BzCl}$  at room temp. into  $\text{Cu}_2\text{Cl}_2$ , (II), (VII), and the  $\text{Cu}^{\text{II}}$  enolate (VIII) of  $\text{CHBzAc}\cdot\text{CO}_2\text{Et}$ . (VIII) and  $\text{HCl}$  (1 equiv.) similarly give an impure  $\text{ClCu}$  enolate,

$\text{C}_{13}\text{H}_{13}\text{O}_4\text{ClCu}$ ; the  $\text{Cu}^{\text{II}}$  enolate of  $\text{COMe}\cdot\text{CH}_2\cdot\text{COPh}$  affords an impure enolate,  $\text{C}_{10}\text{H}_9\text{O}_2\text{ClCu}$ , whilst the  $\text{Cu}^{\text{II}}$  enolate of  $\text{COMe}\cdot\text{CH}_2\cdot\text{COMe}$  and (IV) yield the pure enolates,  $\text{ClCu}\cdot\text{O}\cdot\text{CMe}\cdot\text{CH}\cdot\text{COMe}$  and  $\text{ClCu}\cdot\text{O}\cdot\text{CMe}\cdot\text{CAc}\cdot\text{CO}_2\text{Et}$ , respectively, which with cold  $\text{H}_2\text{O}$  and aq.  $\text{HCl}$  give the original enolates and ketones, respectively. The results are interpreted by the theory (cf. *loc. cit.*) of the formation of polymols. and their subsequent decomp. Related reactions, e.g., the production of  $\text{CH}_2\cdot\text{CO}$  from  $\text{CH}_2\text{Br}\cdot\text{COBr}$  and  $\text{Zn}$ , are discussed briefly.

(VII) and its (liquid) isomeride (IX), b.p.  $139^\circ/1.5$  mm. (from  $\text{CH}_2\text{Ac}\cdot\text{CO}_2\text{Et}$  and  $\text{BzCl}$  in  $\text{C}_5\text{H}_5\text{N}$ ), absorb  $\text{H}_2$  and  $\text{Br}$  at about the same rate; (VII) reacts somewhat faster with  $\text{ONa}\cdot\text{CMe}\cdot\text{CH}\cdot\text{CO}_2\text{Et}$  to give the Na enolate of  $\text{CHBzAc}\cdot\text{CO}_2\text{Et}$ . (VII) and (IX) could not be interconverted by heat or irradiation [whereby (IX) is destroyed and (VII) is unchanged]. It appears doubtful if (VII) and (IX) can be classed as ordinary stereoisomerides. H. B.

$\alpha\alpha$ -Dimethylacetoacetic acid.—See this vol., 432.

Monohydroxypalmitic acid in butter fat.—See this vol., 361.

**Chlorohydroxystearic acids from oleic and elaidic acids.** K. HASHI (J. Soc. Chem. Ind. Japan, 1936, 39, 18B).—Addition of  $\text{HOCl}$  to oleic acid, or of  $\text{HCl}$  to its oxide, yields only a *chlorohydrin*  $\alpha$ , m.p.  $38.0$ — $38.3^\circ$ ; that of  $\text{HCl}$  to elaidic acid oxide gives *chlorohydrins*  $\beta$  and  $\gamma$ , m.p.  $49.5$ — $51.0^\circ$ , and  $68.0$ — $69.5^\circ$ , with scarcely any  $\alpha$ , whereas that of  $\text{HOCl}$  to elaidic acid yields a mixture, half of which is a substance of m.p.  $51.0$ — $55.0^\circ$ . E. W. W.

**Action of alkali metals on dialkylmalonic esters.** F. KROLLFEIFFER and A. ROSENBERG (Ber., 1936, 69, [B], 465—470).—Na powder reacts vigorously with  $\text{CMe}_2(\text{CO}_2\text{Et})_2$  is anhyd.  $\text{Et}_2\text{O}$  giving  $\text{CO}$  (95.3% of amount calc. for elimination of 1  $\text{CO}_2\text{Et}$ ) and  $\text{Pr}^n\text{CO}_2\text{Et}$  (yield 35.8%); the deficit of the latter is attributed partly to volatility, partly to formation of further products; acidic substances are also produced, which are less in evidence when a more difficultly hydrolysable malonate is used. K and  $\text{CEt}_2(\text{CO}_2\text{Et})_2$  react violently giving  $\text{CO}$  (10.4%),  $\text{CHEt}_2\cdot\text{CO}_2\text{Et}$  (29.8%), and  $\text{CO}_2\text{H}\cdot\text{CEt}_2\cdot\text{CO}_2\text{Et}$  (31.5%); the more turbid action with Na affords  $\text{CO}$  (85.4%),  $\text{CHEt}_2\cdot\text{CO}_2\text{Et}$  (46.5%), and dicarbonyl compounds which could not be identified. K and  $\text{CPr}^n_2(\text{CO}_2\text{Et})_2$  yield  $\text{CO}$  (11.6%),  $\text{CHPr}^n_2\cdot\text{CO}_2\text{Et}$  (37.2%), and *Et H di-n-propylmalonate*, m.p.  $43$ — $44^\circ$ ; with Na the products are  $\text{CO}$  (83.2%),  $\text{CHPr}^n_2\cdot\text{CO}_2\text{Et}$  (61%), and minor amounts of acidic products.  $\alpha$ -*n*-Propylvaleranilide has m.p.  $102$ — $103^\circ$ .  $\text{C}(\text{CH}_2\text{Ph})_2(\text{CO}_2\text{Et})_2$  and K react slowly at  $15$ — $20^\circ$ , more vigorously at the b.p. of  $\text{Et}_2\text{O}$ , giving  $\text{CO}$  (4.6%) and  $\text{CH}(\text{CH}_2\text{Ph})_2\cdot\text{CO}_2\text{Et}$  (32.5%) with considerable amounts of acidic products; with Na the products are  $\text{CO}$  (58%),  $\text{CH}(\text{CH}_2\text{Ph})_2\cdot\text{CO}_2\text{Et}$  (38.1%), and very little acidic material. The mechanism of the change is not elucidated. H. W.

**Optically active anhydrides. I. Anhydride of  $d$ - $\alpha$ -methylglutaric acid.** E. BERNER and R. LEONARSEN (Kong. Norske Vidensk. Selsk. Forhandl., 1935, 7, 125—128; Chem. Zentr., 1935, i,

3781—3782).—Fractional crystallisation of the strychnine salt of *dl*- $\alpha$ -methylglutaric acid (I) yields *d*- $\alpha$ -methylglutaric acid, m.p. 81°,  $[\alpha]_D^{20} +20.05^\circ$  in  $H_2O$ ; with  $AcCl$  this affords *d*- $\alpha$ -methylglutaric anhydride, m.p. 50°,  $[\alpha]_D^{20} -38.8^\circ$  in  $H_2O$ . *l*- $\alpha$ -Methylglutaric acid may be obtained by crystallisation of the brucine salt of (I). H. N. R.

**Biochemistry of micro-organisms. XLVIII.** Penicillic acid, a metabolic product of *Penicillium puberulum*, Bainier, and *P. cyclopium*, Westling. J. H. BIRKINSHAW, A. E. OXFORD, and H. RAISTRICK (Biochem. J., 1936, 30, 394—411).—Penicillic acid (I),  $C_8H_{10}O_4$ , m.p. 87° (cryst. from  $H_2O$ ,  $C_8H_{12}O_5$ , m.p. 64—65°), a product of the metabolism of *P. puberulum*, Bainier, and in much larger yield of *P. cyclopium*, Westling, is optically inactive, monobasic, readily loses  $CO_2$ , contains 1 active H, 1 OMe, and gives a monoacetate,  $C_{10}H_{12}O_5$ , m.p. 72°, a condensation product with dimedon,  $C_{16}H_{22}O_6$ , m.p. 204° (decomp.), a  $Br_2$ -derivative,  $C_8H_{10}O_4Br_2$ , m.p. 154—155°, and a  $H_2$ -derivative (II), m.p. 86° (cryst. from  $H_2O$ ,  $C_8H_{14}O_5$ , m.p. 62—64°). On hydrolysis with  $2N-H_2SO_4$ , (I) gives  $CO_2$  (1 mol.) and a substance,  $C_{10}H_{16}O_4$  (bisdinitrophenylhydrazones, m.p. 254°), which probably resulted from the condensation of 2 mols. of  $AcCOEt$ , whilst (II) gives  $CO_2$  (1 mol.) and a substance  $C_6H_{10}O_2$ , probably acetylisobutyl (isolated as a mixture of a bisdinitrophenylhydrazones, m.p. 226—227°, with two monodinitrophenylhydrazones, m.p. 186—187° and 121°, respectively). On hydrolysis with  $0.25N-Ba(OH)_2$ , (I) gives the following:  $CO_2$ ; a substance,  $C_5H_{10}O_2$  (monodinitrophenylhydrazones, m.p. 193—194°);  $AcCOEt$  (bisdinitrophenylhydrazones, m.p. 272—274°); a substance,  $C_8H_{12}O$  (monodinitrophenylhydrazones, m.p. 152—154°); a substance,  $C_{10}H_{10}O_2$ , m.p. 98—102°, a lactonic condensation product;  $MeOH$ ;  $HCO_2H$ . (II) with  $CH_3N_2$  gives a neutral  $Me_1$  ester,  $C_9H_{14}O_4$ , an oil ( $N_2H_4$  derivative, m.p. 207—208°), whilst (I) yields a pyrazoline *Me* ester,  $C_{10}H_{14}O_4N_2$ , m.p. 74°, which with  $NH_2OH$  gives a pyridazone,  $C_9H_{12}O_2N_4$ , m.p. 181°, and with  $NHPh-NH_2$  a phenylpyridazone,  $C_{15}H_{16}O_4N_2$ , m.p. 198—199°. The ozonide of (I) on decomp. gives  $CH_2O$ , indicating the presence of a  $:CH_2$  group; (II) gives no  $CH_2O$ . Neither (I) nor (II) gives ketonic reactions in cold aq. solution, but (I) rapidly absorbs 1 mol., more slowly a second mol., of  $NH_2OH$ , whereas (II) does not absorb  $NH_2OH$ . On heating with  $NH_2OH$ , (I) gives a dioxime,  $C_6H_{10}O_2N_2$ , m.p. 210—212° (decomp.), decarboxylation and demethylation having occurred, whilst (II) gives an orthoxazine,  $C_8H_{11}O_3N$ , m.p. 54—56°. (I) with  $NHPh-NH_2$  gives a phenylpyrazolinephenylhydrazones (III),  $C_{18}H_{20}N_4$ , m.p. 176°, decarboxylation and demethylation occurring. (III) on oxidation with  $PbO_2-AcOH$  gives a phenylpyrazole (IV),  $C_{12}H_{12}ON_2$ , m.p. 72—74° (oxime,  $C_{12}H_{13}ON_3$ , m.p. 149°). (IV) on oxidation with  $NaOI$  gives a monocarboxylic acid (V),  $C_{11}H_{10}O_2N_2$ , m.p. 170°, which with alkaline  $KMnO_4$  gives 1-phenylpyrazole-3 : 4-dicarboxylic acid, m.p. 232° (*Me* ester, m.p. 89°). (V) on thermal decomp. gives 1-phenyl-4-methylpyrazole, m.p. 43°, oxidised with  $KMnO_4$  to 1-phenylpyrazole-4-carboxylic acid,  $C_{10}H_8O_2N_2$ , m.p. 219—221°. These reactions

show that the decarboxylated, demethylated product arising from (I) is  $\beta\gamma$ -diketo- $\delta$ -methylene-pentane (VI). (II) on heating with red  $P-HI$  gives  $\gamma$ -hydroxy- $\delta$ -methylhexoic acid (lactone, b.p. 227—230°; phenylhydrazide, m.p. 126°), thus fixing the point of attachment of the  $CO_2H$  to (VI). (II) with  $KMnO_4$  and with  $O_3$  gives *Me* dimethylpyruvate (monodinitrophenylhydrazones, m.p. 176—178°), which with  $N-NaOH$  gives the free acid (dinitrophenylhydrazones, m.p. 196—197°). The OMe is thus attached to the  $\beta$ -C in (VI). (I) is therefore  $\gamma$ -keto- $\beta$ -methoxy- $\delta$ -methylene- $\Delta^4$ -hexonoic acid and must exist in both keto and lactone forms:

$$CH_2:CMc \cdot CO \cdot C(OMe):CH \cdot CO_2H \rightleftharpoons CH_2:CMc \cdot C(OH) \cdot C(OMe):CH \cdot CO.$$

P. W. C.

**Reversible oxidation of ascorbic acid by norite charcoal.**—See this vol., 390.

**Colorimetric determination of aliphatic aldehydes.** K. FISCHBECK and L. NEUNDEUBEL (Z. anal. Chem., 1936, 104, 81—88).— $CH_2O$ ,  $MeCHO$ , and  $EtCHO$  are determined photometrically by means of the colour developed with 0.01% aq. fuchsin- $H_2SO_3$  (I) in acid solution, using filtered light of 470  $m\mu$ . (I) may be kept without change under  $H_2$ .  $CH_2O$  is warmed with (I) for 5 min. at 80°;  $MeCHO$  and  $EtCHO$  are mixed with (I) at room temp., and examined after a standardised time interval. A large excess of  $EtOH$  has no effect. J. S. A.

**Action of chloral on magnesium  $\beta$ -phenylethyl,  $\gamma$ -phenylpropyl, and  $\delta$ -phenylbutyl bromides.** P. M. DEAN and W. I. WOLF (J. Amer. Chem. Soc., 1936, 58, 332—333).—Chloral (I) (1 mol.) and  $CH_2Ph \cdot CH_2 \cdot MgBr$  (1 mol.) give  $CCl_3 \cdot CH_2 \cdot OH$  (II) ( $\alpha$ -naphthylcarbamate, m.p. 120°), styrene, and  $(CH_2Ph \cdot CH_2)_2$ . Similarly,  $CH_2Ph \cdot CH_2 \cdot CH_2 \cdot MgBr$  and (I) give (II),  $CH_2Ph \cdot CH_2 \cdot CH_2$ , and  $\alpha$ -diphenylhexane;  $CH_2Ph \cdot [CH_2]_3 \cdot MgBr$  affords (II),  $CH_2Ph \cdot CH_2 \cdot CH_2 \cdot CH_2$ , and  $\alpha$ -diphenyloctane. No  $CCl_3 \cdot CHR \cdot OH$  could be isolated. The main product is the olefine (usually isolated as dibromide). H. B.

**Micro-determination of acraldehyde.** I. M. KORENMAN (J. Appl. Chem. Russ., 1935, 8, 1476—1477).—3 ml. of 0.1*N*-I in KI and 1 ml. of 5%  $KOH$  are added to 5—10 ml. of dil. aq. acraldehyde, the solution is made acid with  $H_2SO_4$  after 30 min., and the liberated I is titrated with 0.1*N*- $Na_2S_2O_3$ . Alternatively, the solution is made strongly acid with  $H_2SO_4$ , excess of  $KMnO_4$  is added, the mixture is heated at 100° for 15 min., and  $Na_2C_2O_4$  is added, excess of which is titrated with  $KMnO_4$ . R. T.

**Constitution of Schiff's bases.** J. TURCAN (Bull. Soc. chim., 1936, [v], 3, 283—294).— $CHPr^a:NR$  ( $R=Pr^a$ ,  $C_5H_{11}$ ,  $CH_2Ph$ , and  $Ph$ ) and heptylideneaniline with  $Br$  give  $NH_2R$  (or its  $Br$ -derivatives) and  $CPr^aBr \cdot CHO$  (polymeride, m.p. 95—97°) or bromoheptaldehyde, respectively. Reaction occurs by addition to the  $CMe_2:CH \cdot NHR$  form.  $N_2O_4$ , however, reacts with Schiff's bases in the same way whether a *tert*-C is or is not present, i.e., with the enimine form. Equilibrium between the two forms is thus demonstrated. R. S. C.

**Constitution of oximes.** See this vol., 406.

Quadrivalent compounds of bivalent copper and nickel. See this vol., 410.

Hydrogenation of ketones in presence of nickel and platinised nickel. Influence of alkali. M. DELEPINE and A. HOREAU (Compt. rend., 1935, 201, 1301—1305).—The rate of hydrogenation of COMe<sub>2</sub>, COMeEt, COMe·C<sub>9</sub>H<sub>19</sub>, COMePh,  $\alpha$ -phenyl- $\beta$ -dimethylhexan- $\beta$ -one, cyclohexanone, CH<sub>3</sub>Ac·CO<sub>2</sub>Et, CHEtAc·CO<sub>2</sub>Et, lævulic acid, CHMe·CH·CHO, PhCHO, *o*- and *p*-OH·C<sub>6</sub>H<sub>4</sub>·CHO, galactose, fructose, and  $\alpha$ -diethylaminopentan- $\delta$ -one to alcohols at room temp. and atm. pressure in presence of Raney Ni is greatly increased by addition of a little NaOH. Fixation of the second mol. of H<sub>2</sub> by mesityl oxide, methylheptenone, and CHPh·CH·COMe is similarly accelerated. The effect is not due to enolisation, as it occurs also with COPh<sub>2</sub> and Bz<sub>2</sub>. A similar, but smaller, acceleration is caused by platinising the Ni with a little dil. alkaline PtCl<sub>4</sub>. Pd, Rh, and Ru have slight similar effects. The effects of platinisation and alkali are additive.

R. S. C.

Action of magnesium *tert*-butyl chloride on methyl propyl ketone and ethyl laurate. A. D. PETROV, K. I. KARASEV, and M. A. TSCHELZOVA (Compt. rend. Acad. Sci. U.R.S.S., 1936, 4, 31—33, and Bull. Soc. chim., 1936, [v], 3, 169—176).—With COMePr<sup>a</sup>, MgBu<sup>a</sup>Cl (I) affords some  $\beta$ -*tert*-butyl-pentan- $\beta$ -ol, b.p. 68.8—69.8°/16 mm. (chloride, b.p. 64.2—65.5°/12.5—13 mm.), together with large amounts of products formed by self-condensation of the ketone, but no *tert*-alcohol is obtained with dodecyl ketone (II) (reduced to carbinol, converted into the olefine through the xanthate) (Kipping, J.C.S., 1890, 57, 983). Et laurate and (I) in Et<sub>2</sub>O-xylene at 110—120° give only (II): 2R·CO<sub>2</sub>Et  $\rightarrow$  R<sub>2</sub>CO + CO(CO<sub>2</sub>Et)<sub>2</sub>  $\rightarrow$  CO<sub>2</sub> + Et<sub>2</sub>O (R = C<sub>11</sub>H<sub>23</sub>), but with MgBu<sup>a</sup>Cl it affords  $\epsilon$ -*n*-butylhexadecan- $\epsilon$ -ol (III), b.p. 180—182°/15 mm. (unstable bromide), with partial dehydration to  $\epsilon$ -*n*-butyl- $\Delta^8$ -hexadecene, b.p. 165—167.5°/15 mm., best obtained by dehydration of (III) with H<sub>2</sub>C<sub>2</sub>O<sub>4</sub> at 140—180°. Similar results are obtained with Et palmitate. (I) is not decomposed by heating to 110°.

J. W. B.

Diacetyl. J. PIEN, J. BAISSÉ, and R. MARTIN (Lait, 1936, 16, 119—138).—The formation of a phenylhydrazone is recommended as a qual. test (photomicrographs of the crystals are given). A colorimetric determination (for dilutions down to 1 in 100,000) is described. The reagent used is *m*-tolylenediamine, which reacts to give a yellow colour.

E. B. H.

Nomenclature of methylated sugars. E. VETOČEK (Coll. Czech. Chem. Comm., 1936, 8, 43—45).—It is proposed to designate sugar Me ethers as methylglucose etc. and *C*-Me derivatives as methylglucose etc.

R. S. C.

Formation of osazones. J. KENNER and E. C. KNIGHT (Ber., 1936, 69, [B], 341—343).—The formation of osazones is ascribed to the oxidising action of salts of NHPH·NH<sub>2</sub>. The latter is stable below 300°, but mixtures of it and its hydrochloride commence to evolve gas at 120° and the reaction becomes very vigorous at 165°. From *o*-, *m*-, and

*p*-tolyl- and *p*-bromophenyl-hydrazine gas is rapidly evolved at about 100°, 100°, 115°, and 120°, respectively.

H. W.

Change in optical rotation of glucose in dilute solutions of boric acid. P. S. TANG and P. N. SUNG (Nature, 1936, 137, 275).—Contrary to previous observations (A., 1932, 120), changes occur in  $\alpha$  of glucose in H<sub>3</sub>BO<sub>3</sub> and Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub> at certain concns. For 10% solutions of glucose  $[\alpha]_D$  falls to a sharp min. with 0.13*M*-H<sub>3</sub>BO<sub>3</sub>.

L. S. T.

Simultaneous formation of two isomeric isopropylidene derivatives of 2-methyl- $\gamma$ -methylglucoside. D. J. BELL (J.C.S., 1936, 186—187).—The oily product from 2-methyl- $\gamma$ -methylglucoside, anhyd. CuSO<sub>4</sub>, and 1% H<sub>2</sub>SO<sub>4</sub>·COMe<sub>2</sub> is a mixture of 3:5- and 5:6-isopropylidene derivatives. By methylation (Purdie), hydrolysis (0.5% HCl at 100°), conversion into the  $\beta$ -glucoside, and then into the dinitrate, it yields 2:3-dimethyl- $\beta$ -methylglucoside 4:6-dinitrate, m.p. 99—100° (lit. 98—99°). The material from the mother-liquor with Zn and Fe in AcOH gives impure 2:6-dimethyl- $\beta$ -glucoside, characterised as 3:4-di-*p*-toluenesulphonate, m.p. 157—158°.

R. S. C.

Condensation products of acetoacetic ester.

IV. Two highly reactive compounds of glucose and acetoacetic ester. C. U. MOORE, R. J. ERLANGER, and E. S. WEST (J. Biol. Chem., 1936, 113, 43—47).—Et glucosycycloacetoacetate (I) (A., 1927, 1173) is oxidised by HgSO<sub>4</sub> at room temp. to a non-cryst. hygroscopic substance (II), C<sub>12</sub>H<sub>18</sub>O<sub>8</sub>, m.p. 65—72°,  $[\alpha]_D^{25}$  —70.9° in H<sub>2</sub>O (no mutarotation). (II) rapidly reduces cold Fehling's solution, and immediately becomes reddish-brown when treated with alkali. It gives unstable products with NHPH·NH<sub>2</sub> and NH<sub>2</sub>OH, and immediately affords CHI<sub>3</sub> with KOI. It contains 3 OH and 1 Ac. Treatment of it with BzCl in CHCl<sub>3</sub>-C<sub>5</sub>H<sub>5</sub>N affords a Bz<sub>2</sub> derivative, C<sub>26</sub>H<sub>26</sub>O<sub>10</sub>, m.p. 45—49°,  $[\alpha]_D^{25}$  —52.5° in abs. EtOH (no mutarotation). Oxidation of (I) with BzO<sub>2</sub>H in H<sub>2</sub>O-EtOAc containing BaCO<sub>3</sub> at 7° gives an isomeric product, C<sub>12</sub>H<sub>18</sub>O<sub>8</sub>, m.p. 57—60°,  $[\alpha]_D^{25}$  —33.4° in H<sub>2</sub>O, which closely resembles (II), but contains only 2 OH groups which are reactive towards Ac<sub>2</sub>O.

H. W.

Oxidation of  $\alpha$ -methyl-*d*-mannopyranoside.

E. L. JACKSON and C. S. HUDSON (J. Amer. Chem. Soc., 1936, 58, 378—379).—Oxidation [aq. Ba(OBr)<sub>2</sub>] of  $\alpha$ -methyl-*d*-mannopyranoside (I) removes C<sub>3</sub> and gives the acid (II), CO<sub>2</sub>H·CH(OMe)·O·CH(CO<sub>2</sub>H)·CH<sub>2</sub>·OH (*Sr* salt,  $[\alpha]_D^{25}$  —53° in H<sub>2</sub>O), which does not reduce Fehling's solution. Hydrolysis (hot H<sub>2</sub>O) of (II) and subsequent oxidation (Br-H<sub>2</sub>O) affords H<sub>2</sub>C<sub>2</sub>O<sub>4</sub> and *d*-glyceric acid. (II) is also obtained by successive oxidation of (I) or  $\alpha$ -methyl-*d*-glucoside with HIO<sub>4</sub> and Br-H<sub>2</sub>O; (II) should be similarly produced from all the  $\alpha$ -methyl-*d*-aldohexopyranosides.

H. B.

Glucoside derivatives. E. JOLLES [in part with M. BOTRINI] (Gazzetta, 1935, 65, 1217—1221).—*Æseulin tetra*-, m.p. 270° (decomp.),  $[\alpha]_D^{18}$  +46.9° (all rotations in C<sub>5</sub>H<sub>5</sub>N), *amygdalin hexa*-, m.p. 267° (decomp.),  $[\alpha]_D^{18}$  —25.4°, *arbutin tetra*-, m.p. 224—225° (decomp.),  $[\alpha]_D^{18}$  +23.3°, and *salicin penta*-(*N*-phenyl-

carbamate), m.p.  $204^{\circ}$  (decomp.),  $[\alpha]_D^{18} -42.8^{\circ}$ , are obtained by action of PhNCO on the respective glucosides in  $C_5H_5N$ . E. W. W.

**Saponins from seeds of *Barringtonia asiatica*, Kurz.** Constituents of the sugar part of  $A_1$ -barrinin.—See this vol., 396.

**Saponin-like substance of radix clematidis.** See this vol., 396.

**Glycosides of the flowers of *Linaria vulgaris*, L.** Constitution of linarin and pectolinarin. K. W. MERZ and Y. H. WU (Arch. Pharm., 1936, 274, 126—148; cf. Schmid and Rumpel, A., 1931, 738; 1932, 621).—Extraction of the dried flowers with  $Et_2O$  removes fatty material from which hentriacontane is isolated. Further extraction with EtOH gives mannitol, the phenolic linarin (I),  $C_{28}H_{32}O_{14} \cdot H_2O$  (cf. Klobb, A., 1908, i, 903), m.p.  $256^{\circ}$  (decomp.) (rapid heating),  $[\alpha]_D^{18} -100.1^{\circ}$  in AcOH, and amorphous pectolinarin (II),  $C_{29}H_{34}O_{15}$ , m.p.  $240-250^{\circ}$  (decomp.). (I) gives a  $Ac_7$  derivative (III) ( $+2H_2O$ ), m.p.  $123-125^{\circ}$ , and is hydrolysed (conc. HCl) to glucose, rhamnose, and linareginin (IV),  $C_{16}H_{12}O_5$ , m.p.  $262^{\circ}$  (decomp.) [ $Ac_2$ , m.p.  $200^{\circ}$ ,  $Bz_2$ , m.p.  $200^{\circ}$ , and  $Br_2$ , m.p.  $257^{\circ}$  (decomp.), derivatives; *Me ether* ( $CH_2N_2$ ), m.p.  $170^{\circ}$ ; *Me ether acetate* (V), m.p.  $196^{\circ}$ ]. The  $Ac_1$  derivative obtained from (III) and AcOH-HBr in  $CHCl_3$  is methylated ( $CH_2N_2$ ) to (V). (IV) is degraded by conc. KOH in  $H_2$  to  $HCO_2H$ , anisic acid [also formed by oxidation (30%  $H_2O_2$  in 15% KOH) of (IV)], *s*- $C_6H_3(OH)_3$ , and *p*-OMe- $C_6H_4$ -COMe. (IV) is, therefore, 5:7-dihydroxy-4'-methoxyflavone; the disaccharide residue in (I) is at  $C_7$ . (IV) is identical with acacetin (Hattori, A., 1925, i, 1443), but (I) differs from acaciin (*loc. cit.*). (II) is hydrolysed (conc. HCl) to glucose, rhamnose, and pectolinarigenin (VI),  $C_{15}H_8O_4(OMe)_2$ , m.p.  $215-216^{\circ}$  [ $Ac_2$  derivative, m.p.  $151^{\circ}$ ; *Me ether* ( $CH_2N_2$ ), m.p.  $188^{\circ}$ ; *Me ether acetate* (VII), m.p.  $168^{\circ}$ ; *Me\_2 ether* ( $Me_2SO_4$ ), m.p.  $162^{\circ}$ , identical with 5:6:7:4'-tetramethoxyflavone (Robinson and Schwarzenbach, A., 1930, 735)]. The  $Ac_1$  derivative obtained from the  $Ac_7$  derivative, m.p.  $134-138^{\circ}$ , of (II) and AcOH-HBr in  $CHCl_3$  is methylated to (VII). Degradation (KOH) of (VI) gives  $HCO_2H$ , anisic acid, 2:4:6-(OH) $_3C_6H_2$ -OMe and *p*-OMe- $C_6H_4$ -COMe. (VI) is 5:7-dihydroxy-6:4'-dimethoxyflavone. (II) is the 6-OMe-derivative of (I). H. B.

**Cellulose of native composition from cotton wool.** II. E. SCHMIDT, W. JANDEBEUR, M. HECKER, R. SCHNEGG, and M. ATTERER [with W. HAHN and J. W. PEDLOW] (Ber., 1936, 69, [B], 366—374; cf. A., 1935, 610).—Cellulose from cotton wool and linters which has not been subjected to chemical treatment but has been purified by the  $ClO_2$  method contains 0.28% of  $CO_2H$ . This val. is unchanged by dissolution of the material in  $CuO-NH_3$  and repptn. by AcOH or  $(NH_4)_2SO_4$ , and is also observed in similarly treated specimens not purified with  $ClO_2$ . Since the latter specimens are free from all known impurity, it follows that cellulose is the sole carrier of 0.28%  $CO_2H$  and is a carboxylic acid. If 0.28% of  $CO_2H$  is present the material is unaffected by the action of  $CuO-NH_3$  and AcOH or  $(NH_4)_2SO_4$ , but a

variation from this % is accompanied by oxidation, frequently with marked increase in the % of  $CO_2H$ . Native cellulose (I) therefore consists of a chain of 96  $C_6$  units. The presence of 0.28% of  $CO_2H$  can be used as a criterion of the unaltered condition of (I), but natural conditions appear to exist which induce alteration in the crude material. (I) is changed by NaOH,  $NH_3$ ,  $CaCO_3$ , and many other substances at room temp.; possibly the fermentative degradation of (I) in the soil is preceded by the action of  $CaCO_3$ . The action of  $Cl_2$  in  $H_2O$  on (I) causes increase in the % of  $CO_2H$ , and even in very dil. solution the reagent is unsuitable for the scientific investigation of polymeric carbohydrates. The technical processes of purifying cotton wool and linters cause chemical alteration in (I). H. W.

**X-Ray studies of reactions of cellulose in non-aqueous systems. I. Interaction of cellulose and liquid ammonia.** A. J. BARRY, F. C. PETERSON, and A. J. KING (J. Amer. Chem. Soc., 1936, 58, 333—337).—Cellulose (ramie) (I) swells in liquid  $NH_3$  and gives  $NH_3$ -cellulose (II) (approx. 1 mol. of  $NH_3$  per  $C_6H_{10}O_5$ ), the X-ray diagram of which resembles that of  $N_2H_4$ -cellulose (Trogus and Hess, A., 1932, 149). (II) loses all its  $NH_3$  at  $105^{\circ}$  and passes into cellulose II [the X-ray diagram of which resembles that of hydrate cellulose (III)], which regenerates (II) when treated with liquid  $NH_3$ . (II) could not be obtained from (I) and dry  $NH_3$  or dil. or conc. aq.  $NH_3$ . (I) is recovered from (II) by treatment with  $H_2O$ , dil. AcOH, or dil. or conc. aq.  $NH_3$ . (III) and liquid  $NH_3$  give a product resembling (II). H. B.

**Perchlorates as solvents for cellulose and its derivatives.**—See this vol., 426.

**Carbonisation of ramie cellulose studied by means of X-rays and the "net density method."** C. PARK (Mem. Coll. Sci. Kyoto, 1935, A, 18, 311—313).—As the temp. of carbonisation,  $t$ , is raised from  $260^{\circ}$  to  $290^{\circ}$ , the X-ray pattern of the C changes from that of ramie cellulose to that of amorphous C, and  $d$  is a min. when  $t$  is approx.  $290^{\circ}$ . J. G. A. G.

**Organic cupritetra-chlorides and -bromides.**—See this vol., 438.

**McCrae's test [for salicylic acid]: special test for hexamethylenetetramine.** F. W. CHENG (J. Chem. Eng. China, 1935, 2, 137—138).—McCrae's test depends on the production of a pink colour with  $CH_2O$  and  $H_2SO_4$  disappearing on dilution with  $H_2O$ . It is more sensitive than the  $FeCl_3$  test and is applicable to derivatives without previous hydrolysis. The addition of  $H_2SO_4$  to  $(CH_2)_6N_4$  (I) liberates  $CH_2O$  so the test can be used for detection of (I). C. I.

**[Compounds of] copper ferrocyanide ammoniate.**—See this vol., 443.

**Synthesis of  $\alpha$ -amino- $\beta$ -hydroxypropane.** P. A. LEVENE [with M. KUNA] (J. Biol. Chem., 1936, 113, 153—156).— $CHMeBr \cdot CO_2H$  is added gradually to a solution of Li in  $CH_2Ph \cdot OH$  and the mixture is heated to  $150^{\circ}$ , whereby *r*- $\alpha$ -benzyloxypropionic acid (I), b.p.  $123-128^{\circ}/0.2$  mm., is obtained. It is slowly resolved by cinchonidine in  $COMe_2$ , the most sparingly sol. salt giving 1- $\alpha$ -benzyloxypropionic acid, b.p.  $125-$

128°/0.5 mm.,  $[\alpha]_D^{25} - 62.5^\circ$  in  $C_6H_6$ . *r*- $\alpha$ -Benzoyloxypropionyl chloride, b.p. 79—81°/0.5 mm., is converted by  $NH_3$  in MeOH at  $-10^\circ$  into *r*- $\alpha$ -benzyloxypropionamide, transformed by boiling  $SOCl_2$  into *r*- $\alpha$ -benzyloxypropionitrile (II), b.p. 91—93°/1 mm. Reduction (Raney) of (II) affords  $\alpha$ -amino- $\beta$ -benzyloxypropane (hydrochloride; platinichloride, m.p. 207°), whilst treatment with  $H_2$  in AcOH containing colloidal Pd gives *r*- $\alpha$ -amino- $\beta$ -hydroxypropane (platinichloride).

H. W.

Triethyl- $\beta$ -hydroxyethylammonium hydr-oxide.—See this vol., 510.

Synthesis of taurine. F. CORTESE (J. Amer. Chem. Soc., 1936, 58, 191—192).—Taurine, decomp. 300—305° (corr.) [*N*-phenylcarbamyl derivative, decomp. 195—200° (corr.)], is prepared in 80% yield from  $CH_2Br \cdot CH_2 \cdot NH_2 \cdot HBr$ , m.p. 174—175° (corr.) (modified prep.; cf. Gabriel, A., 1917, i, 541), and aq.  $Na_2SO_3$ .

H. B.

Alkaline hydrolysis of polypeptides [derived from] *l*-alanine. P. S. YANG (J. Chinese Chem. Soc., 1936, 4, 37—41).—The rate of hydrolysis of *l*-alanyl-, di-, tri-, and tetra-*l*-alanyl-*l*-alanine by 0.2*N*. and *N*-NaOH at 25° is independent of the nature of the peptide, but is much greater with the more conc. alkali. Racemisation occurs only at the beginning of the reaction; at least 3  $NH_2$ -acid units must be present for it to occur.

R. S. C.

Behaviour of *dl*-serine, *dl*-phenylalanine, *dl*-alanine, *dl*-lactic acid, and propionic acid towards X-rays and ultra-violet light.—See this vol., 437.

Photo-decomposition of *l*-aspartic acid, *l*-asparagine, and glycylglycine.—See this vol., 437.

Action of alkaline potassium hypobromite solutions on the amides of acylated amino-acids. S. J. KANEVSKAJA (Ber., 1936, 69, [B], 266—273).—The formation of cyclic compounds during the Hofmann reaction is characteristic only of amides of acylated  $\beta$ - $NH_2$ -acids; it is very probable that the change can be used for the determination of  $\beta$ - $NH_2$ -acids even when they are present in complex natural mixtures. Succinimide is converted by treatment with KOBr followed by KOH and BzCl into  $\beta$ -benzamidopropionic acid, m.p. 120° (yield 51%), transformed by successive treatment with  $SOCl_2$  and  $NH_3 \cdot CHCl_3$  into  $\beta$ -benzamidopropionamide (I), m.p. 170—171°. (I) is converted by KOBr- $H_2O$  at 80° into BzOH and tetrahydroglyoxal-2-one, m.p. 131°. Under similar conditions, hippuramide is converted into benzamidomethylamine (hydrochloride, m.p. 189—190°); occasionally, the reaction is accompanied by oxidation with production of  $NH_2Bz$ .  $NH_2 \cdot [CH_2]_3 \cdot CO_2H \cdot HCl$  is transformed by KOH and a slight excess of BzCl into  $\gamma$ -benzamidobutyric acid (II), m.p. 75° (yield 90%), the Me ester, m.p. 59—60°, of which yields  $\gamma$ -benzamidobutyramide (III), m.p. 122—123°, with  $NH_3 \cdot EtOH$ . (III) and KOBr afford benzamidotrimethyleneamine (hydrochloride, m.p. 150—160°). (II) is converted by  $SOCl_2$  or boiling  $Ac_2O$  into 1-benzoylpyrrolidone, m.p. 91—92°; if the change is effected at a very low temp. and the product

is treated with  $NH_3$  in  $CHCl_3$ ,  $\gamma$ -benzamidobutyramide, m.p. 122—123°, is isolated in about 10% yield.

H. W.

Reactions of maleimide. E. JOLLES (Gazzetta, 1935, 65, 1221—1225).—Maleimide in  $C_5H_5N$  and  $NHPh \cdot OH$  yield a substance,  $C_{10}H_{10}O_3N_2$ , m.p. 178°, regarded as phenylhydroxyaminosuccinimide, which is oxidised by  $FeCl_3$  to  $PhNO$ , and on prolonged heating in  $C_5H_5N$  loses  $H_2O$  to form anilinomaleimide, new m.p. 209°.  $NHPh \cdot OH$  with *o*- $C_6H_4(CO)_2O$  forms *o*- $C_6H_4(CO)_2NPh$ ; does not react with *o*- $C_6H_4(CO)_2NH$ ; and with succinimide or pyrrole gives resinous products.

E. W. W.

Colorimetric determination of carbamide; its determination in blood, cerebrospinal fluid, and tissues. J. A. SANCHEZ (J. Pharm. Chim., 1936, [viii], 23, 188—199).—0.5—4 c.c. of 0.01%  $CO(NH_2)_2$  solution and 1 c.c. of 0.02%  $NaNO_2$  solution are mixed and made up to 10 c.c. with  $H_2O$ ; 2 c.c. of pure liquid paraffin and then 30 drops of conc.  $H_2SO_4$  are added. The mixture is kept at 60° for 25 min. 1 c.c. of a solution of 0.5 g. of *p*- $NH_2 \cdot C_6H_4 \cdot SO_3H$  and 0.75 g. of  $PhOH$  in 100 c.c. of 2.5%  $H_2SO_4$  is added and the colour (due to azo-dye formed by the excess of  $HNO_2$ ) is measured after 5 min.  $CO(NH_2)_2$  is determined in defibrinated (Folin's reagent) whole blood, plasma, or serum by matching against standard solutions.

R. S. C.

Cupric and cuprous compounds of thiosemicarbazide and of its derivatives. V. HARLAY (Compt. rend., 1936, 202, 324—325).— $NH_2 \cdot NH \cdot CS \cdot NH_2$  with  $CuSO_4$ ,  $Cu(NO_3)_2$ , and  $CuCl_2$  gives the sulphate, nitrate, and chloride of Cu thiosemicarbazide in which the metal is linked to two org. residues through S. Acetonethiosemicarbazone in  $COMe_2 \cdot H_2O$  with  $Cu(NO_3)_2$  and  $NH_3$  gives the Cu derivative [hydrochloride and sulphate (each +1  $COMe_2$ ) when cryst. from  $COMe_2$ ], which when boiled with aq.  $COMe_2$  gives the  $Cu^I$  derivative (sulphate and hydrochloride are unstable to  $H_2O$ ).  $NH_2 \cdot NH \cdot CS \cdot NH_2 \cdot HCl$  with  $Cu_2O$  gives the  $Cu^I$  derivative,  $[CuS \cdot C(NH_2) \cdot N \cdot NH_2]HCl$ , easily oxidised in air.

J. L. D.

Theory of biuret reaction. P. S. YANG (J. Chinese Chem. Soc., 1936, 4, 27—36).—*l*-Asparagine and the amides of *dl*-leucine, *d*-alanine, and glycine form amorphous biuret compounds,  $CuX_2$ , m.p. 302—304° (decomp.), 248—250°, 229—231°, and 205—207°, respectively, in absence of alkali, the first two with  $CuSO_4$  or  $Cu(OAc)_2$ , the last two only with  $Cu(OH)_2$ . To form a biuret compound a substance must have a N carrying a replaceable H and a N which can co-ordinate with Cu, separated by  $\geq 3$  atoms; in some cases the two N are provided by different mols., in which case 4 mols. of the compound combine with 1 Cu.

R. S. C.

Rubidium and caesium fulminates.—See this vol., 438.

Preparation of hydroxamic acids. G. ODDO and E. DELEO (Ber., 1936, 69, [B], 287—294).—Hydroxamic acids are immediately formed when an aldehyde sol. in  $H_2O$  is treated with 1 mol. of  $NH_2OH$  in  $EtOH \cdot H_2O$  and then with 2 equivs. of 30%  $H_2O_2$ .

As the solubility of the aldehyde in  $H_2O$  diminishes reaction takes place less readily and to a limited extent and does not occur when the solubility is slight. MeOH or EtOH cannot be substituted for  $H_2O$ , since they are immediately oxidised to the corresponding aldehyde. No change takes place in  $COMe_2$ . If a suspension of the aldehyde in  $H_2O$  is used, a sudden reaction leads to resinous products. Since the reaction is confined to aldehydes sol. in  $H_2O$ , the possibility is excluded that it depends on a primary production of the oxime which is then oxidised by  $H_2O_2$  or that  $NH_2OH$  is oxidised by  $H_2O_2$  to  $NOH$  which is added to the aldehyde. The scheme,  $RCHO + NH_2OH = OH \cdot CHR \cdot NH \cdot OH$  (I), and  $(I) + H_2O_2 = 2H_2O + OH \cdot CR \cdot N \cdot OH$  is suggested. In support of this view it is shown that  $CCl_3 \cdot CH(OH)_2$  gives small amounts of the product  $CCl_3 \cdot CH(OH) \cdot NH \cdot OH$  and  $CHCl_2 \cdot CH(OH)_2$  yields the unstable adduct  $CHCl_2 \cdot CH(OH) \cdot NH \cdot OH$ , which immediately decomposes into chloroacetylhydroxamic acid (Cu salt) and  $OH \cdot CH \cdot N \cdot OH$ . Under defined conditions MeCHO and  $NH_2OH$  give the substance  $OH \cdot CHMe \cdot NH \cdot OH$ , immediately transformed by  $H_2O_2$  into  $OH \cdot CMe \cdot N \cdot OH$ . The prep. of  $OH \cdot CH \cdot N \cdot OH$ ,  $OH \cdot CMe \cdot N \cdot OH$ ,  $OH \cdot CEt \cdot N \cdot OH$  (Cu salt), and  $OH \cdot CPr^a \cdot N \cdot OH$  (Cu salt) is described in detail. H. W.

Additive products of aldehydes with the disodium salt of nitrohydroxylamine and with benzenesulphonhydroxamic acid; non-existence of the nitrosyl of A. Angeli. G. ODDO and E. DELEO (Ber., 1936, 69, [B], 294—298).—No evidence is obtained of the intermediate formation of nitrosyl  $NOH$ ,  $OHN$ , or  $HN(OH)_2$  by the action of the reagents on  $NH_2OH$  and its subsequent union with the aldehyde to the hydroxamic acid and Angeli's hypothesis should be discarded.  $CCl_3 \cdot CH(OH)_2$  and  $SO_2Ph \cdot NH \cdot OH$  at room temp. slowly yield the adduct,  $CCl_3 \cdot CH(OH) \cdot N(OH) \cdot SO_2Ph$ , which does not give the reactions of hydroxamic acids and is decomposed by warm alkali into  $PhSO_2K$ ,  $CCl_3 \cdot C(OH) \cdot N \cdot OK$ ,  $H_2O$ , and a colourless, cryst. compound probably of cyclic nature. Similarly,  $p-OMe \cdot C_6H_4 \cdot CHO$  and  $SO_2Ph \cdot NH \cdot OH$  afford the compound  $OMe \cdot C_6H_4 \cdot CH(OH) \cdot N(OH) \cdot SO_2Ph \cdot H_2O$ , m.p. 153—154°, also obtained in presence of  $KOH$  if heating is avoided. MeCHO and  $ONa \cdot N \cdot NO_2Na$  give the adduct,  $OH \cdot CHMe \cdot N(ONa) \cdot NO_2Na$ ,  $ONa \cdot N \cdot NO_2Na$ , whilst under similar conditions EtCHO yields the substance  $2OH \cdot CEt \cdot N(ONa) \cdot NO_2Na$ ,  $ONa \cdot N \cdot NO_2Na$ , each of which when dissolved in  $H_2O$  give the reactions of hydroxamic acids. H. W.

Formation of organo-metalloidal compounds by micro-organisms. IV. Dimethyl- and methylallyl-*n*-propylarsine. F. CHALLENGER and A. A. RAWLINGS (J.C.S., 1936, 264—267).—*P. brevicaulis* on bread crumbs with  $AsMePr^aO_2H$  or  $AsEtPr^aO_2H$  gives  $AsMe_2Pr^a$  and methylallyl-*n*-propylarsine (also obtained, b.p. 129—130°, from  $MgMeI$  and  $AsEtPr^aI$ ) [dimercurichloride, m.p. 171—172° (decomp. 188—189°); mercurichloride, m.p. 137—138°; benzylpicrate, m.p. 65—66°;  $HNO_3$  leads to methylallyl-*n*-propylhydroxyarsonium picrate, m.p. 108—109°], respectively. Phenyldimethylarsine mer-

curichloride, m.p. 193—194°, and phenylbenzylidimethylarsonium picrate, m.p. 125—126°, are described. R. S. C.

Basic organic salts of bismuth, soluble in organic solvents. M. PICON (Bull. Soc. chim., 1936, [v], 3, 176—185).—The prep. of bismuthyl cyclohexanolacetate,  $\alpha$ -carbethoxy- $\Delta^a$ -nonenoate,  $\alpha$ -carbethoxy- $\beta$ -phenyl-*n*-butyrate,  $\alpha$ -carbethoxycyclohexylacetate, camphorcarboxylate, and carboxymethylnonoate, by double decomp. between the Na salt and  $Bi(NO_3)_3$  in glycerol is described. These derivatives are sol. in org. solvents, especially  $CHCl_3$ ,  $C_6H_6$ ,  $CCl_4$ , and  $CS_2$ . E. S. H.

Preparation of tin alkyl and aryl trihalides. A. TOHAKIRIAN, M. LESBRE, and M. LEVINSOHN (Compt. rend., 1936 202, 138—140).— $KSnCl_3 \cdot H_2O$  (Rimbach *et al.*, A., 1916, ii, 332) reacts with the appropriate RI at 90—110° to give (%) yields in parentheses)  $SnMeI_3$  (43·7), *Sn Et tri-iodide*, b.p. 181—184·5°/19 mm. (37), *Sn Pr<sup>a</sup> tri-iodide*, b.p. 200°/16 mm. (<25), *Sn Ph tri-iodide*, decomp. > 220° (reaction temp. 210°), all formed thus:  $KSnCl_3 + RI \rightarrow KI + RSnCl_3 + 3KI \rightarrow 3KCl + RSnI_3$ ; and *Sn Pr<sup>3</sup> trichloride*, b.p. 75°/16 mm. (> 40). J. W. B.

Configuration of bisdimethylglyoximeammine cobaltic chloride. R. TSUCHIDA, M. KOBAYASHI, and A. NAKAMURA (Bull. Chem. Soc. Japan, 1936, 11, 38—40).—By a method for showing the optical activity of racemic substances by asymmetric adsorption on quartz when other methods are not available (J. Chem. Soc. Japan, 1935, 56, 1339), it has been found that the above compound is a *dl*-mixture, and is therefore a *cis*-compound, or has the dimethylglyoxime groups in the 1:2 instead of the 1:6 positions. M. S. B.

Substituted cyclohexyl nitrites. L. HUNTER and J. A. MARRIOTT (J.C.S., 1936, 285—286).—cycloHexyl nitrite, b.p. 31°/10 mm., rapidly decomposes yielding adipic acid. 2-Iodocyclohexyl nitrite, b.p. 110—117°/20—25 mm. (decomp.), is also unstable; 1-phenylcyclohexyl nitrite decomposes when distilled at 10 mm. 1-, b.p. 46°/12 mm., 2-, b.p. 42°/10 mm., 3-, b.p. 45°/12 mm., and 4-methyl-, b.p. 45°/14 mm., 1-ethyl-, b.p. 63°/15 mm., 2-bromo-, b.p. 87°/10 mm., and 2-chloro-cyclohexyl nitrite, b.p. 71°/12 mm., are, however, stable for > 6 months. 2-Bromocyclohexanol, b.p. 103—104°/18 mm., is unstable. R. S. C.

Bixin solutions as colorimetric standards for determination of carotene.—See this vol., 396.

Carotene. X. Comparison of absorption spectra measurements on  $\alpha$ - and  $\beta$ -carotene and lycopene. J. H. C. SMITH (J. Amer. Chem. Soc., 1936, 58, 247—255).—Curves are given for  $\alpha$ - (I) and  $\beta$ - (II) -carotenes and lycopene (III) using an improved photo-electric spectrophotometer (described in detail). The absorption coeffs. of solutions in EtOH-Et<sub>2</sub>O (20%) agree well with those found by Miller *et al.* (A., 1935, 1189); the curves for (I) and (II) are essentially the same as those previously found (A., 1934, 458) for solutions in 95% EtOH. The "pure carotene" of McNicholas (A., 1931, 1110) is (II). The coeffs. for solutions of (I), (II), and (III) in  $CS_2$  differ

considerably from those reported in the lit. (cf. Smakula, A., 1934, 1324). Variations in the positions of the absorption max. of (I) and (II), determined by spectrophotometric and spectroscopic methods (supplemented by a Cu-NH<sub>4</sub> filter), are probably due to superposition of the absorption of the filter on that of the pigment; the former should be the standard method.

H. B.

**Significance of non-localised linkings of aromatic hydrocarbons in formation of their molecular compounds with dipolar molecules.**—See this vol., 410.

**Beryllium bromide as a catalyst in the bromination of benzene.** M. F. TABOURY and R. PAJEAU (Compt. rend., 1936, 202, 328—330).—C<sub>6</sub>H<sub>6</sub> (86 g.) is readily brominated in presence of BeBr<sub>2</sub> (> 3 g.). Excess of Br converts C<sub>6</sub>H<sub>6</sub> or PhBr into *p*-C<sub>6</sub>H<sub>4</sub>Br<sub>2</sub> in good yield.

J. L. D.

**Purification and determination of the degree of purity of toluene.** W. SWIENTOSEWSKI and E. RAMOTOWSKI (Rocz. Chem., 1935, 15, 422—429).—Pure PhMe, b.p. 110.612/4°, is readily obtained by fractionation with a series of condensers, or with a special column ensuring slow distillation. Admixture of 1:1 C<sub>6</sub>H<sub>6</sub>-xylene does not affect the b.p., but increases the difference between the b.p. and the temp. of condensation of the vapour by 0.001° per 0.0024% of mixture present.

R. T.

**Mechanism of aromatic side-chain reactions.** VII.—See this vol., 433.

**Action of sulphinates on 2:4-dinitrophenylsulphones.** J. D. LOUDON (J.C.S., 1936, 218—221).—ArSO<sub>2</sub>Na reacts with *o*- and *p*-(NO<sub>2</sub>)<sub>2</sub>-compounds, replacing 1 NO<sub>2</sub>. The combination, 1-NO<sub>2</sub>-3-ArSO<sub>2</sub>, activates ArSO<sub>2</sub> or Cl in the 6 position, which can then be replaced by Cl, NH<sub>2</sub>, OH, or ArSO<sub>2</sub>, etc. Examples are given, in which Ar=Ph, *p*-C<sub>6</sub>H<sub>4</sub>Me, and *m*-C<sub>6</sub>H<sub>4</sub>NO<sub>2</sub>. The constitutions in the PhSO<sub>2</sub> series are rigidly proved; the others follow by analogy. 2:4-(NO<sub>2</sub>)<sub>2</sub>C<sub>6</sub>H<sub>3</sub>·SO<sub>2</sub>Ph and PhSO<sub>2</sub>Na (I) in hot aq. dioxan or (CH<sub>2</sub>OH)<sub>2</sub> yield 1-nitro-2:5-diphenylsulphonylbenzene (II), m.p. 157—158°, which with hot piperidine gives 3-nitro-4-piperidinodiphenylsulphone, m.p. 133°, and with NaOH-EtOH gives 3-nitro-4-ethoxy-, m.p. 147°, and -hydroxy-diphenylsulphone, m.p. 137°. 1-Nitro-2:5-di-*p*-tolylsulphonylbenzene (III) (similarly prepared), m.p. 220—221°, gives similarly 3-nitro-4-piperidino-, forms, m.p. 96—97° and (stable) 107—108°, respectively, -hydroxy-, m.p. 157—158°, and -ethoxy-4'-methylidiphenylsulphone, m.p. 143—144°. The appropriate chloronitro- or (NO<sub>2</sub>)<sub>2</sub>-compounds with (I) or *p*-C<sub>6</sub>H<sub>4</sub>Me·SO<sub>2</sub>Na in hot (CH<sub>2</sub>OH)<sub>2</sub> yield *o*-, m.p. 147°, and *p*-nitro-, m.p. 143°, and 2-, m.p. 156°, and 4-nitro-4'-methylidiphenylsulphone, m.p. 170°. Reduction by SnCl<sub>2</sub>-HCl-EtOH affords 2-, m.p. 120—121°, and 4-amino-4'-methylidiphenylsulphone (IV), m.p. 181°. *p*-Sulphonamidodiphenylsulphone (prep. in C<sub>2</sub>H<sub>5</sub>N), m.p. 190°, and hot HNO<sub>3</sub>-AcOH yield the 3-NO<sub>2</sub>-derivative, m.p. 171°, hydrolysed by warm conc. H<sub>2</sub>SO<sub>4</sub> to 3-nitro-4-aminodiphenylsulphone (V), m.p. 169—170°, which is also obtained from (II) and conc. aq. NH<sub>3</sub> at 130°. (IV) gives similarly its *p*-C<sub>6</sub>H<sub>4</sub>Me·SO<sub>2</sub>

11

derivative, m.p. 213—214°, which with hot HNO<sub>3</sub>-AcOH affords 3:5-dinitro-, m.p. 221°, and 3-nitro-4-*p*-toluenesulphonamido-4'-methylidiphenylsulphone, m.p. 129—130°, hydrolysed to 3:5-dinitro-, m.p. 216° after softening at 205°, and 3-nitro-4-amino-4'-methylidiphenylsulphone (VI), m.p. 184° [also obtained from (III) and NH<sub>3</sub>]. 4-Chloro-3-nitrobenzenesulphonyl chloride (modified prep.), m.p. 61—62° (lit. 40° and 60°), with AlCl<sub>3</sub> and C<sub>6</sub>H<sub>6</sub> gives 4-chloro-3-nitrodiphenylsulphone, m.p. 127°, which is also obtained (diazo-reaction) from (V) and gives the same piperidino-, OH-, and NH<sub>2</sub>-derivatives as does (II). 4-Chloro-3-nitro-4'-methyl- [obtained from (VI)], m.p. 120°, and 2-chloro-5-nitro-diphenylsulphone (obtained from 2-chloro-5-nitrobenzenesulphonyl chloride), m.p. 174°, undergo similar reactions; 5-nitro-2-piperidinodiphenylsulphone has m.p. 178°. Nitration of 4-chlorodiphenylsulphone yields, according to the conditions, the 3'-NO<sub>2</sub>-, m.p. 139—140° (also obtained from *m*-NO<sub>2</sub>·C<sub>6</sub>H<sub>4</sub>·SO<sub>2</sub>Cl, AlCl<sub>3</sub>, and PhCl), or 3:3'-(NO<sub>2</sub>)<sub>2</sub>-derivative, m.p. 146°, which latter leads to 3:3'-dinitro-4-piperidino-, m.p. 151—152°, and -4-amino-diphenylsulphone, m.p. 238°. 4-Chloro-4'-methylidiphenylsulphone gives similarly 4-chloro-3'-nitro-, m.p. 103°, and -3:3'-dinitro-, m.p. 152°, and 3:3'-dinitro-4-piperidino-, m.p. 149—150°, and -4-amino-4'-methylidiphenylsulphone, m.p. 231°. The requisite chloronitro-compound and Na arylsulphinate in aq. EtOH or dioxan yield (II), (III), 1-nitro-5-phenylsulphonyl-2-*p*-tolyl-, m.p. 180°, 1-nitro-2-phenylsulphonyl-5-*p*-tolyl-, m.p. 212°, 1-nitro-2-phenylsulphonyl-5-*m*-nitrophenyl-, m.p. 233°, and 1-nitro-5-*m*-nitrophenylsulphonyl-2-*p*-tolyl-sulphonylbenzene, m.p. 232°.

R. S. C.

**Naphthalene series. V. 8-Chloro-1-nitronaphthalene and 8-chloro- $\alpha$ -naphthol.** N. N. VOROSCHCOV and V. V. KOSLOV (Ber., 1936, 69, [B], 412—415).—Treatment of 1:8-NO<sub>2</sub>·C<sub>10</sub>H<sub>6</sub>·SO<sub>3</sub>Na with HCl (*d* 1.19) and NaClO<sub>3</sub>-H<sub>2</sub>O in C<sub>6</sub>H<sub>4</sub>Cl<sub>2</sub> at 96—98° and distillation of the product with steam affords the two forms of 8:1-C<sub>10</sub>H<sub>6</sub>Cl·NO<sub>2</sub>, m.p. 94—95° (I) and 125°, respectively, and some 8:1-C<sub>10</sub>H<sub>6</sub>Cl·OH, m.p. 67°, formed by hydrolysis. Chlorination of 1-C<sub>10</sub>H<sub>7</sub>·NO<sub>2</sub> in presence of FeCl<sub>3</sub> at 60—70° affords (I), 5:1-C<sub>10</sub>H<sub>6</sub>Cl·NO<sub>2</sub>, C<sub>10</sub>H<sub>7</sub>Cl, and 1:4:5-C<sub>10</sub>H<sub>5</sub>Cl<sub>3</sub>.

H. W.

**Preparation of halogenomethyl derivatives of naphthalene hydrocarbons. Synthesis of 1:2- and 1:4-dimethylnaphthalenes.** G. DARZENS and A. LÉVY (Compt. rend., 1936, 202, 73—75).—C<sub>10</sub>H<sub>8</sub> with a solution of trioxymethylene in AcOH-HCl at 60° gives 95% (on C<sub>10</sub>H<sub>8</sub> used) of 1-C<sub>10</sub>H<sub>7</sub>·CH<sub>2</sub>Cl, b.p. 148—150°/13 mm., m.p. 32°; the use of HBr leads to 1-C<sub>10</sub>H<sub>7</sub>·CH<sub>2</sub>Br, m.p. 56°. 1-C<sub>10</sub>H<sub>7</sub>·Me similarly gives 1:4-C<sub>10</sub>H<sub>6</sub>Me·CH<sub>2</sub>Cl, b.p. 124—125°/2 mm., m.p. 62° (picrate, m.p. 73—74°), oxidised (alkaline KMnO<sub>4</sub>) to 1:4-C<sub>10</sub>H<sub>6</sub>(CO<sub>2</sub>H)<sub>2</sub> and reduced (Al, EtOH-HCl) to 1:4-C<sub>10</sub>H<sub>6</sub>Me<sub>2</sub>. 2-C<sub>10</sub>H<sub>7</sub>·Me affords 2:1-C<sub>10</sub>H<sub>6</sub>Me·CH<sub>2</sub>Cl, b.p. 125—126°/2 mm., m.p. 65° (picrate, m.p. 99°), similarly reduced to 1:2-C<sub>10</sub>H<sub>6</sub>Me<sub>2</sub>, b.p. 265°/770 mm., m.p. —3.5° (picrate, m.p. 130°). Small amounts of liquid products are also formed from the C<sub>10</sub>H<sub>7</sub>Me. H. B.

### Photochemical formation of organic diradicals III.—See this vol., 437.

**Dissociable anthracene oxides: effect of meso-tolyl groups.** A. WILLEMART (Compt. rend., 1936, 202, 140—141).—Reduction of the appropriate 9:10-dihydroxy-9:10-diaryldihydroanthracene with KI-AcOH affords 9:10-di-o-, m.p. 350°, di-m-, m.p. 221—222° (block) and di-p-tolylanthracene (Ingold *et al.*, A., 1927, 141), all giving dissociable oxides (evolve O<sub>2</sub> at 180—200°) when illuminated (sunlight) in solution in presence of air. The o-substituent is least effective in promoting reversible oxidation.

J. W. B.

**Dissociable organic oxides. Naphthacene formula of the rubenes.** Synthesis of 5:6:11:12-tetraphenyl-naphthacene; its identity with tetraphenylrubene (old rubrene). C. DUFRASSE and L. VELLUZ (Compt. rend., 1935, 201, 1394—1396).—6:11-Dihydroxynaphthacene-5:12-quinone and

MgPhBr give 5:12-diphenyl-naphthacene-6:11-quinone, m.p. 284°; with more MgPhBr this yields 6:11-dihydroxy-5:6:11:12-tetraphenyl-naphthacene, converted by loss of H<sub>2</sub>O into dehydro-rubrene (I) and by reduction into 5:6:11:12-tetraphenyl-naphthacene, identical with rubrene. Bis-2:2'-(1-hydroxy-3-ketoindenyl) gives substances not belonging to

the rubene series (cf. A., 1935, 1492). The formation of dissociable rubene oxides is due to the 5-, 6-, 11-, and 12-C (cf. CPh<sub>3</sub> and mesodiallylanthracenes).

R. S. C.

**m-Nitrobenzoylthiocarbimide as a reagent for the identification of amines.** W. L. TUNG, CHENG HENG KAO, CHUNG HSI KAO, and P. P. T. SAH (Sci. Rep. Tsing Hua Univ., 1935, 3, [4], 285—289).—m-Nitrobenzoylthiocarbimide, m.p. 94—95°, is obtained by heating NH<sub>4</sub>NCS in COMe<sub>2</sub> with m-NO<sub>2</sub>-C<sub>6</sub>H<sub>4</sub>-COCl (I) in C<sub>6</sub>H<sub>6</sub>. For use as a reagent its isolation is unnecessary and the m-nitrobenzoylthiocarbamates of the following amines are prepared by slow addition of their solution in warm COMe<sub>2</sub> to a hot mixture of NH<sub>4</sub>NCS and (I) in COMe<sub>2</sub> and treatment of the product with cold H<sub>2</sub>O:NH<sub>2</sub>Ph, m.p. 153—154°; o-, m.p. 184—185°, m-, m.p. 194—195°, and p-, m.p. 178—179°, -NO<sub>2</sub>-C<sub>6</sub>H<sub>4</sub>-NH<sub>2</sub>: α-, m.p. 180—181°, and β-, m.p. 194—195°, -C<sub>10</sub>H<sub>7</sub>-NH<sub>2</sub>: o-, m.p. 184—185°, m-, m.p. 126—127°, and p-, m.p. 158—159°, -C<sub>6</sub>H<sub>4</sub>Me-NH<sub>2</sub>: NHPh<sub>2</sub>, m.p. 150° (decomp.); p-C<sub>6</sub>H<sub>4</sub>Cl-NH<sub>2</sub>, m.p. 160—161°; p-C<sub>6</sub>H<sub>4</sub>Br-NH<sub>2</sub>, m.p. 175—176°; m-nitro-, m.p. 174—175°, and m-bromo-, m.p. 182—183°, p-toluidine; o-, m.p. 205° (decomp.), and p-, m.p. 221—222°, -NH<sub>2</sub>-C<sub>6</sub>H<sub>4</sub>-CO<sub>2</sub>H: NHPhMe, m.p. 135—136°.

H. W.

**Peroxidase action. I. Oxidation of aniline.** P. J. G. MANN and B. C. SAUNDERS (Proc. Roy. Soc., 1935, B, 119, 47—60).—NH<sub>2</sub>Ph (2% solution in dil. AcOH) is readily oxidised by the peroxidase (I) from horse-radish or turnips in presence of H<sub>2</sub>O<sub>2</sub> (concn. maintained at 10—20 mg.-%) at p<sub>H</sub> 4.5 and room temp.; benzoquinone-1-anil-4-p-aminoanilinoanil (II)

is considered to be an intermediate (causing a transient bluish-violet colour), whilst the substances isolated (by fractional extraction of the brown reaction product with various solvents) are 2:5-dianilinobenzoquinone-1-imine-4-anil (III) (Ac derivative, m.p. 212°), probably induline 3B (IV) (and a little induline 6B), ψ-mauveine (V), and ungreenable aniline-black (VI) [modified structure suggested (cf. Green and Wolff, A., 1913, i, 302)]. p-Benzoquinone and azobenzene are not isolated. The following reactions are considered to occur: (a) NH<sub>2</sub>Ph → NHPh-OH → p-NH<sub>2</sub>-C<sub>6</sub>H<sub>4</sub>-NHPh → NH-C<sub>6</sub>H<sub>4</sub>-NHPh → (II); (b) the conversion of (II) through emeraldine (VII) and nigraniline into (VI); (c) conversion of NH-C<sub>6</sub>H<sub>4</sub>-NHPh into (III) and thence through the dianil and a phenazine into (IV); (d) oxidative condensation of NH<sub>2</sub>-C<sub>6</sub>H<sub>4</sub>-N-C<sub>6</sub>H<sub>4</sub>-NHPh and NH<sub>2</sub>Ph to give (V). Schemes (a) and (b) are supported by the observed formation of (VII) from p-NH<sub>2</sub>-C<sub>6</sub>H<sub>4</sub>-NHPh and (I) (as above); (II) is again an intermediate. (VII) is also formed directly from NHPh-OH and (I), presumably by condensation of 8 mols. and subsequent oxidation. Oxidation (Fenton's reagent) of NH<sub>2</sub>Ph in dil. AcOH gives azobenzene and 2-amino-5-anilino- (VIII) and 2:5-dianilino-benzoquinone-1-anil, m.p. 202° [also formed from (VIII) and NH<sub>2</sub>Ph in AcOH].

H. B.

**Orthanilic acid (aniline-o-sulphonic acid).** E. WERTHEIM (Org. Syntheses, 1935, 15, 55—58).—o-NO<sub>2</sub>-C<sub>6</sub>H<sub>4</sub>-SO<sub>2</sub>Cl, prepared from (o-NO<sub>2</sub>-C<sub>6</sub>H<sub>4</sub>-S<sub>2</sub>)<sub>2</sub>, HNO<sub>3</sub>, and Cl<sub>2</sub>, is hydrolysed and the sulphonic acid reduced with Fe in AcOH.

CH. ABS. (f)

**2:4-Dinitroaniline.** F. B. WELLS and C. F. B. ALLEN (Org. Syntheses, 1935, 15, 22—23).—1:2:4-C<sub>6</sub>H<sub>3</sub>Cl(NO<sub>2</sub>)<sub>2</sub> and AcO<sub>2</sub>NH<sub>4</sub> yield 2:4-(NO<sub>2</sub>)<sub>2</sub>-C<sub>6</sub>H<sub>3</sub>-NH<sub>2</sub>. The method cannot be applied to C<sub>6</sub>H<sub>4</sub>Cl-NO<sub>2</sub>.

CH. ABS. (r)

**Complex salts of α-phenylethylamine. Equivalence of the four co-valencies of bivalent platinum and palladium.** H. REIHLEN and E. FLOHR (Ber., 1936, 69, [B], 325—330).—Werner's hypothesis of the equivalence of covalencies is applicable without exception to hexacovalent compounds, and to quadricovalent substances with the exception of certain Pt and Pd compounds of which so many isomerides are known that their existence as stereoisomerides requires special *ad hoc* suppositions. Jørgenson's proof of the equivalence of the linkings in tetramminoplatinous dihalides is regarded as unconvincing. It is sought to obtain more suitable conditions by the use of chemically similar but readily differentiated amines [(+) and (-)-CHPhMe-NH<sub>2</sub>], which, with Pd, afford sufficiently labile derivatives. The replacement of amine linked to Pd by amine in solution, however, takes place so readily that the results throw no light on the problem. K<sub>2</sub>PtCl<sub>4</sub> and (+)-CHPhMe-NH<sub>2</sub> in H<sub>2</sub>O at 15—20° afford tetra-(+)-α-phenylethylaminoplatinous dichloride, [α]<sub>D</sub><sup>20</sup> +62.5° in 50% EtOH. Tetra-(+)-α-phenylethylaminopalladium dichloride, [α]<sub>D</sub><sup>20</sup> +69.0° in abs. EtOH, from PdCl<sub>2</sub> and amine in abs. EtOH at > 45°, and the corresponding 1-compound, [α]<sub>D</sub><sup>20</sup> -72° in H<sub>2</sub>O, -69.2° in abs. EtOH, are transformed by HCl at 60° into the trans-compounds

[Pd(CHPhMe·NH<sub>2</sub>)<sub>2</sub>Cl<sub>2</sub>], [ $\alpha$ ]<sub>D</sub> -65.5° (I) and +65.8° (II) in abs. EtOH, respectively. (I) and *r*-CHPhMe·NH<sub>2</sub> (2 mols.) in abs. EtOH at 35° afford *trans-di(-)di(r)-phenylethylaminopalladium dichloride*, [ $\alpha$ ]<sub>D</sub> -33° in abs. EtOH. Similarly (I) with (+)-CHPhMe·NH<sub>2</sub> (2 mols.) or (II) with (-)-CHPhMe·NH<sub>2</sub> (2 mols.) yields the optically inactive *tetra-r- $\alpha$ -phenylethylaminopalladium dichloride*. (II) and (-)-CHPhMe·NH<sub>2</sub> (6 mols.) afford *tri(-)-mono(+)- $\alpha$ -phenylethylaminopalladium dichloride*, [ $\alpha$ ]<sub>D</sub> -36° in abs. EtOH. H. W.

**Naphthalene series. VI. Transformation of diazotised 8-nitro- $\alpha$ -naphthylamine.** N. N. VOROSCHCOV and V. V. KOSLOV (Ber., 1936, 69, [B], 416—419).—1:8-NO<sub>2</sub>·C<sub>10</sub>H<sub>6</sub>·SO<sub>2</sub>H (I), m.p. 151—152° (Cu and Na salts), is readily obtained by adding a solution of diazotised 1:8-NO<sub>2</sub>·C<sub>10</sub>H<sub>6</sub>·NH<sub>2</sub> to H<sub>2</sub>SO<sub>3</sub> in presence of Cu powder. The nearly neutral diazo-solution and Na<sub>2</sub>S+S afford 1:1'-*di-nitrodinaphthyl 8:8'-disulphide* (II), m.p. 212—214°. Attempts to prepare 1:8-NO<sub>2</sub>·C<sub>10</sub>H<sub>6</sub>·SH were unsuccessful. Mild reduction of (II) leads to the amino-mercaptan or naphthasultam (III), m.p. 174.5°. Reduction of (I) with glucose in EtOH also gives (III). 8-Nitro- $\alpha$ -naphthol, m.p. 212° (decomp.) (Ba and Pb salts), does not couple with diazo-compounds, but apparently gives diazo-oxides. H. W.

**Amide condensations. I. Preparation of acetoacetylphenylamide.** G. V. TSCHELINCEV and E. D. OSSETROVA (Ber., 1936, 69, [B], 374—377).—NEt<sub>2</sub>Ac is unchanged by Na in Et<sub>2</sub>O, whereas NPh<sub>2</sub>Ac and Na in C<sub>6</sub>H<sub>6</sub> at 100° afford *acetoacetylphenylamide* (I), m.p. 86—87°, and NHPH<sub>2</sub> in excellent yield. (I) gives a dark violet colour with FeCl<sub>3</sub> in EtOH and is hydrolysed by 18% HCl to COMe<sub>2</sub> and NHPH<sub>2</sub>·HCl. The analogy between the reaction and ester condensation is stressed. H. W.

**Derivatives of  $\alpha\beta$ -diphenylethane.** D. N. KUR-SANOV and A. S. KITSCHINA (J. Gen. Chem. Russ., 1935, 5, 1342—1347).—1-Benzamido-2- $\beta$ -chloroethylbenzene and C<sub>6</sub>H<sub>6</sub> in presence of AlCl<sub>3</sub> yield 2-benzamido- $\alpha\beta$ -diphenylethane, m.p. 157—158.8°, from which the amine, b.p. 138—143°/2 mm. (*hydrochloride*, decomp. at 171°), is obtained by hydrolysis with 10% KOH at 155—160° (5—6 hr.). 4-Nitro- $\alpha\beta$ -diphenylethane is obtained from [CH<sub>2</sub>Ph]<sub>2</sub> and BzNO<sub>2</sub> (3 hr. at room temp.). R. T.

**Aromatic lactams. (MLLE.)** G. GLOTZ (Bull. Soc. chim., 1936, [v], 3, 511—515).—The intensity of the ultra-violet absorption of *o*-C<sub>6</sub>H<sub>4</sub>(NH<sub>2</sub>)<sub>2</sub>, *o*-C<sub>6</sub>H<sub>4</sub>(NH<sub>2</sub>)<sub>2</sub>CO, and *ox-o-phenyleneamide*, sublimes at 330°, increases in the order quoted; one CO has a feeble bathochromic effect. The curve for *o*-C<sub>6</sub>H<sub>4</sub>(NHAc)<sub>2</sub> shows a slight inflexion at about 2650 Å.; *malon-o-phenyleneamide*, darkens at 328°, shows a max. at about 2900 Å., whilst *succin-o-phenyleneamide*, m.p. 232°, exhibits max. at 2800 and 2400 Å. and min. at 2600 and 2200 Å. The amides are prepared by Meyer's method (A., 1906, i, 765). H. B.

**Ortho- and meta-tellurates of benzidine.** M. PATRY (Compt. rend., 1936, 202, 64—66).—The compound Te(OH)<sub>6</sub>(C<sub>6</sub>H<sub>4</sub>·NH<sub>2</sub>)<sub>2</sub> was prepared by

adding an EtOH solution of benzidine (> 30% EtOH) to aq. orthotelluric acid. The compound H<sub>2</sub>TeO<sub>4</sub>(C<sub>6</sub>H<sub>4</sub>·NH<sub>2</sub>)<sub>2</sub> was prepared similarly, using an aq. or EtOH solution of polymetatelluric acid. Excess of base must be used in each case. Solubility data are given. H. J. E.

**Preparation of methyl-substituted azo- and azoxy-benzenes and rearrangement of the azoxy-benzenes.** T. PARSONS, jun., and J. C. BAILAR, jun. (J. Amer. Chem. Soc., 1936, 58, 268—271).—3-Methoxy- and 2- and 3-methyl-azobenzenes are prepared from PhNO and C<sub>6</sub>H<sub>4</sub>R·NH<sub>2</sub> in EtOH-AcOH. 4-Methyl- and 2:2', 3:3', and 4:2'-dimethyl-diazoaminobenzenes (the positions in the ring attached to NH are indicated, e.g., 2'), prepared by Mehner's method (A., 1902, i, 576), are rearranged by a modification of Goldschmidt's procedure (A., 1888, 685, 1283) to 4'-amino-4-methyl- and 2:3', -3:2', m.p. 85—86° (lit. 80°), and 4:3', m.p. 131—132° (lit. 128°), -dimethyl-azobenzene, respectively [*benzenesulphonyl* derivatives (A), m.p. 159°, 138—139°, 144°, and 152—153°, respectively], which are subsequently deaminated (diazo-method) to the methylazobenzenes. Reduction (Fe, dil. AcOH) of (A) gives the appropriate NH<sub>2</sub>Ar and *p*-NH<sub>2</sub>·C<sub>6</sub>H<sub>4</sub>·NH·SO<sub>2</sub>Ph, 4:2-NH<sub>2</sub>·C<sub>6</sub>H<sub>3</sub>Me·NH·SO<sub>2</sub>Ph (I), *benzenesulphon-4'-amino-3'-methylanilide*, m.p. 146° (also prepared by reduction of the 4'-NO<sub>2</sub>-derivative, m.p. 139°), and (I), respectively. The above azobenzenes are then oxidised (30% H<sub>2</sub>O<sub>2</sub> in AcOH) to the azoxybenzenes, which are rearranged by short treatment with 85% H<sub>2</sub>SO<sub>4</sub> at 88° to *p*-hydroxyazobenzenes (except when the 4 and 4' positions are substituted). 2- and 3-Methylazoxybenzenes give 4-hydroxy-2- and -3-methylazobenzene, respectively; the OH thus enters the substituted ring. 4-Methyl- and 3:3'-dimethyl-azoxybenzene afford 4-hydroxy-4'-methyl- (cf. Bigiani and Sabatelli, A., 1927, 1180) and -3:3'-dimethyl-azobenzene, respectively, whilst the 4:4'-Me<sub>2</sub> derivative gives (probably) 20% of 3-hydroxy-4:4'-dimethyl-, m.p. 210—212° (Et ether, m.p. 50°; benzyl ether, m.p. 123°; benzoate, m.p. 122—123°), and 75% of 4-methyl-4'-hydroxymethyl-azobenzene, m.p. 208—210° (decomp.) (benzoate, m.p. 121—122°), both of which are reduced (Fe, AcOH) to *p*-C<sub>6</sub>H<sub>4</sub>Me·NH<sub>2</sub>. 2-Ethoxy-4:4'-dimethylazobenzene, m.p. 76°, is prepared from 4-amino-3-ethoxytoluene and *p*-C<sub>6</sub>H<sub>4</sub>Me·NO. H. B.

**Expulsion of the arylazo-group in *o*-amino-naphthaleneazo-derivatives.** G. B. CRIPPA and G. PERRONCITO (Gazzetta, 1935, 65, 1250—1253).—4:2-C<sub>10</sub>H<sub>6</sub>Br·NH<sub>2</sub> (I) with PhN<sub>2</sub>Cl dissolved in isomyl alcohol forms 4-bromo-1-benzeneazo- $\beta$ -naphthylamine, m.p. 154°, which is degraded by *o*-C<sub>6</sub>H<sub>4</sub>(CO)<sub>2</sub>O to 4-bromo-2-phthalimidonaphthalene, m.p. 125° [also obtained from (I)], and thus does not share the unusual stability of its isomeride, 4-bromo-2-benzeneazo- $\alpha$ -naphthylamine (A., 1935, 1490). E. W. W.

**Action of aliphatic carbimides on hydrazine derivatives.** C. C. P. FACILLY (Rec. trav. chim., 1936, 55, 101—121).—NR<sub>2</sub>:C=O with NR'R''·NH<sub>2</sub> in inert solvents yields NR'R''·NH·CO·NHR. The following new *semicarbazides* were prepared and the

regularities between their m.p. noted: 1-phenyl-4-n-propyl-, m.p. 135°, -4-isopropyl-, m.p. 147°; 1-o-tolyl-4-methyl-, m.p. 143°, -4-ethyl-, m.p. 130°; -4-n-propyl-, m.p. 113°, -4-isopropyl-, m.p. 110°; 1-m-tolyl-4-methyl-, m.p. 145°, -4-ethyl-, m.p. 127°; -4-n-propyl-, m.p. 104°, -4-isopropyl-, m.p. 126°; 1-p-tolyl-4-methyl-, decomp. 192°, -4-ethyl-, m.p. 174°, -4-n-propyl-, m.p. 123°, -4-isopropyl-, m.p. 161°; 1-p-bromophenyl-4-methyl-, m.p. 191°, -4-ethyl-, m.p. 162°, -4-n-propyl-, m.p. 144°, -4-isopropyl-, decomp. 179°; 1-o-nitrophenyl-4-methyl-, decomp. 224°, -4-ethyl-, decomp. 182°, -4-n-propyl-, decomp. 176°, -4-isopropyl-, decomp. 190°; 1-m-nitrophenyl-4-methyl-, decomp. 186°, -4-ethyl-, decomp. 199°, -4-n-propyl-, decomp. 127°, -4-isopropyl-, decomp. 166°; 1-p-nitrophenyl-4-methyl-, decomp. 224°, -4-ethyl-, decomp. 231°, -4-n-propyl-, decomp. 198°, -4-isopropyl-, decomp. 226°; 1-(5-chloro-2-nitro)-phenyl-4-methyl-, decomp. 240°, -4-ethyl-, decomp. 215°, -4-n-propyl-, decomp. 200°, -4-isopropyl-, decomp. 215°; 1-(5-bromo-2-nitro)phenyl-4-methyl-, decomp. 247°, -4-ethyl-, decomp. 223°, -4-n-propyl-, decomp. 212°, -4-isopropyl-, decomp. 234°; 1-(2:4-dinitro)phenyl-4-methyl-, decomp. 222°, -4-ethyl-, decomp. 218°, -4-n-propyl-, decomp. 187°, -4-isopropyl-, decomp. 206°; 1-benzoyl-4-methyl-, m.p. 181°, -4-ethyl-, m.p. 175°, -4-n-propyl-, m.p. 172°, -4-isopropyl-, m.p. 198°; 1-β-naphthyl-4-methyl-, decomp. 192°, -4-ethyl-, m.p. 136°, -4-n-propyl-, m.p. 133°, -4-isopropyl-, decomp. 185°; 1-phenyl-1:4-dimethyl-, m.p. 183°, -1-methyl-4-ethyl-, m.p. 97°, -1-methyl-4-n-propyl-, m.p. 63°, -1-methyl-4-isopropyl-, m.p. 124°; 1-phenyl-1-benzyl-4-methyl-, m.p. 161°, -4-ethyl-, m.p. 107°, -4-n-propyl-, m.p. 65°, -4-isopropyl-, m.p. 97°; 1-p-nitrophenyl-1:4-dimethyl-, decomp. 224°, -1-methyl-4-ethyl-, decomp. 229°, -1-methyl-4-n-propyl-, decomp. 187°; 1:4-diphenyl-4-methyl-, m.p. 192°, -4-ethyl-, m.p. 188°, -4-n-propyl-, m.p. 145°, -4-isopropyl-, m.p. 193°.

F. R. G.

**Action of aliphatic secondary bases on halogen derivatives of amines.** C. VASSILLADES (Bull. Soc. chim., 1936, [v], 3, 160—163).— $\text{NHEt}_2$  (2 mols.) and the appropriate *N*-chloro-amide or -imide (1 mol.) in dry  $\text{COMe}_2$  give benz-, m.p. 112—113°, *phthal*-, cryst., hygroscopic, and *succin*-*as*-diethylhydrazide, m.p. 105—106°, *acet*-, m.p. 168—169°, and *benz*-*as*-phenyl-diethylhydrazide, m.p. 152—153°, and *acet*-*as*-*p*-tolyl-diethylhydrazide, m.p. 140—145°.  $\text{NHAcBr}$ , however, brominates  $\text{NHEt}_2$ ;  $\text{NEt}_2\text{Cl}$  gives  $\text{NHEt}_2\text{HCl}$  and  $\text{NEt}:\text{CHMe}$ , which with  $\text{H}_2\text{O}$  affords probably  $\text{NH}_2\text{Et}$  and  $\text{MeCHO}$ .

R. S. C.

**Influence of nuclear substitution on [the formation and oxidation of] *as*-arylbenzylhydrazines.** M. BUSCH and K. LANG (J. pr. Chem., 1936, [ii], 144, 291—312).—*as*-Arylarylmethylhydrazines,  $\text{NH}_2\text{NAr}\cdot\text{CH}_2\text{Ar}'$  (I), are obtained from  $\text{NH}_2\text{NAr}$  and  $\text{CH}_2\text{Ar}'\text{Cl}$  (usually in  $\text{EtOH}$  at 100—125°), except when Ar is *p*- $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot$  or, occasionally, *o*- $\text{C}_6\text{H}_4\text{Me}$  and *o*- $\text{C}_6\text{H}_4\text{Br}$  (especially if Ar' is  $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot$ ); in these cases  $\text{NHAr}\cdot\text{N}:\text{CHAR}'$  (II) are formed. Whether (II) result by rearrangement and oxidation of (I) or by dehydrogenation of  $\text{NHAr}\cdot\text{NH}\cdot\text{CH}_2\text{Ar}'$  is not clear. An *o*-substituent in Ar' renders reaction more difficult. Oxidation ( $\text{HgO}$  in  $\text{CHCl}_3$  at 0°) of (I)

usually results, especially when Ar is substituted, in the production of (II); in some cases, (II) and the tetrazene,  $(\text{N}:\text{NAr}\cdot\text{CH}_2\text{Ar}')_2$  (III), are produced. It is doubtful if (II) are formed by way of (III) (cf. Flaschner, A., 1905, i, 936). The following (II) are formed directly: *p*- $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{NH}\cdot\text{N}:\text{CHPh}$  (80% yield in xylene at 135°; a little *p*- $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{NH}\cdot\text{CH}_2\text{Ph}$  also produced); *o*-, m.p. 174° (65% yield), *m*-, m.p. 169°, and *p*-, m.p. 163°, -nitrobenzaldehyde-*o*-tolyl-hydrazones; *o*-nitrobenzaldehyde-*o*-bromophenylhydrazones, m.p. 158°; *p*- $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{NH}\cdot\text{N}:\text{CH}\cdot\text{C}_6\text{H}_4\cdot\text{NO}_2\cdot\text{p}$ ; *p*- $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{NH}\cdot\text{N}:\text{CH}\cdot\text{C}_6\text{H}_4\cdot\text{Cl}\cdot\text{o}$  (in xylene at 140°). The following (I) are prepared: *as*-*o*-, *m*-, and *p*-tolylbenzylhydrazines (hydrochlorides, m.p. 176°, 166°, and 161°, respectively; *CHPh*: derivatives, m.p. 93°, 145°, and 138°, respectively, oxidised to  $\text{C}_6\text{H}_4\text{Me}\cdot\text{NH}\cdot\text{N}:\text{CHPh}$ ; *as*-*o*-chlorophenylbenzylhydrazine, m.p. 67° [hydrochloride, m.p. 219° (decomp.)]; *CHPh*: derivative, m.p. 95°, oxidised to *o*- $\text{C}_6\text{H}_4\text{Cl}\cdot\text{NH}\cdot\text{N}:\text{CHPh}$  and a little *di*-*o*-chlorophenyl-dibenzyltetrazene, m.p. 137°; *as*-phenyl-*o*-nitrobenzylhydrazine (*CHPh*:), m.p. 138°, and *m*- $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CH}$ : m.p. 147°, derivatives, oxidised at 0° to diphenyldi-*o*-nitrobenzyltetrazene (66%) (Flaschner, loc. cit.) and *o*- $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CH}\cdot\text{N}:\text{NHPh}$  (34%) (at 25° and 55°, the % are 37, 63 and 0, 100, respectively); *as*-phenyl-*m*-nitrobenzylhydrazine (hydrochloride, decomp. 185—187°; *CHPh*:, m.p. 145°, and *o*-, m.p. 125°, *m*-, m.p. 132°, and *p*-, m.p. 189°, - $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CH}$ : derivatives), accompanied by a little *m*- $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CH}\cdot\text{N}:\text{NHPh}$ ; *as*-phenyl-*p*-nitrobenzylhydrazine [*CHPh*:, m.p. 96°, *o*-, m.p. 111°, and *m*-, m.p. 150°, - $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CH}$ : and *p*- $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CH}$ : m.p. 141° (lit. 132°), derivatives], oxidised to diphenyldi-*p*-nitrobenzyltetrazene (60%), red (stable) and yellow forms, both m.p. 163—164° (decomp.), and a little *p*- $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CH}\cdot\text{N}:\text{NHPh}$ ; *as*-phenyl-*o*-chlorobenzylhydrazine [hydrochloride, m.p. 208° (decomp.)]; *p*- $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CH}$ : derivative, m.p. 122°, accompanied by a little *o*- $\text{C}_6\text{H}_4\text{Cl}\cdot\text{CH}\cdot\text{N}:\text{NHPh}$ ; *as*-*m*-tolyl-*o*- [hydrochloride, m.p. 195—197° (decomp.)]; *o*-, m.p. 136°, and *p*-, m.p. 174°, - $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CH}$ : derivatives], *m*- [hydrochloride, m.p. 188—190° (decomp.)], and *p*- [hydrochloride, decomp. 213—215°] -nitrobenzylhydrazines, oxidised to *o*-, m.p. 125°, *m*-, m.p. 124°, and *p*-, m.p. 113°, -nitrobenzaldehyde-*m*-tolyl-hydrazones, respectively; *as*-*p*-tolyl-*o*-, m.p. 96°, *m*- [hydrochloride, m.p. 180—182° (decomp.)], and *p*-, m.p. 77°, -nitrobenzylhydrazines (the last is accompanied by a little *p*-nitrobenzaldehyde-*p*-tolylhydrazones, m.p. 160°); *as*-*o*- [hydrochloride, m.p. 199—201° (decomp.)], *m*- [hydrochloride, m.p. 156—158° (decomp.)]; *p*- $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CH}$ : derivative, m.p. 129°, and *p*- [hydrochloride, m.p. 183° (decomp.)]; *p*- $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CH}$ : derivative, m.p. 168°] -tolyl-*o*-chlorobenzylhydrazines, all of which are oxidised to oily products; *as*-*o*-chlorophenyl-*o*-, m.p. 59° (hydrochloride, decomp. 160°; *p*- $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CH}$ : derivative, m.p. 176°, and *p*-, m.p. 89° [hydrochloride, m.p. 198° (decomp.)]; *p*- $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CH}$ : derivative, m.p. 186°] -nitrobenzylhydrazines, oxidised to *o*- $\text{C}_6\text{H}_4\text{Cl}\cdot\text{NH}\cdot\text{N}:\text{CH}\cdot\text{C}_6\text{H}_4\cdot\text{NO}_2$ ; *as*-*o*-chlorophenyl-*o*-chlorobenzylhydrazine (hydrochloride, m.p. 166°; *CHPh*: derivative, m.p. 82°), oxidised to *o*- $\text{C}_6\text{H}_4\text{Cl}\cdot\text{NH}\cdot\text{N}:\text{CH}\cdot\text{C}_6\text{H}_4\text{Cl}\cdot\text{o}$ .

H. B.

**Influence of degree of acidity on the velocity of the diazotisation reaction.** H. A. J. SCHOUTSEN (J. Amer. Chem. Soc., 1936, 58, 259—262; cf. A., 1921, ii, 34).—The velocity of diazotisation of  $p\text{-C}_6\text{H}_4\text{Me}\cdot\text{NH}_2$ ,  $o$ -,  $m$ -, and  $p\text{-C}_6\text{H}_4\text{Cl}\cdot\text{NH}_2$ , and  $o\text{-NH}_2\cdot\text{C}_6\text{H}_4\cdot\text{CO}_2\text{H}$  in presence of varying amounts of HCl is not inversely  $\propto$  the excess of HCl; reaction does not, therefore, occur between free  $\text{NH}_2\text{Ar}$  and  $\text{HNO}_2$ . The results with small concns. of HCl show that reaction takes place between  $[\text{NH}_3\text{Ar}]\text{Cl}$  and  $\text{HNO}_2$ . The velocity coeffs. (which do not agree with calc. vals.) increase with rise in concn. of HCl owing to decreased hydrolysis of the salt and a sp. action (being investigated further). H. B.

**Chemistry of diazoamino-compounds.** J. C. EARL (Chem. and Ind., 1936, 192—193).—A brief review.

**Mesohydry.** V. Acyltriazenes; particularly marked instance of mesohydric isomerism. G. ODDO and A. ALGERINO (Ber., 1936, 69, [B], 279—282; cf. A., 1932, 44).—Gradual addition of diazotised  $\text{NH}_2\text{Ph}$  to  $\text{NH}_2\text{Ac}$  in  $\text{H}_2\text{O}$  at  $0^\circ$  gives colourless *acetylphenyltriazene* (I), m.p.  $101\text{--}102^\circ$ , the  $A_g$  salt of which is not affected by  $\text{PhBr}$  or  $\text{MeI}$  in  $\text{MeOH}$ . When exposed to light (I) is rapidly transformed into a red *isomeride* (II), m.p.  $96^\circ$ , re-converted into (I) by dissolution in  $\text{NaOH}$  and pptn. with  $\text{HCl}$ . The absence of colour in (I) cannot be explained by any of the usual formulæ, and the mesohydric constitutions  $\text{AcN}\text{---}\text{N}\text{---}\text{NPh}$  and  $\text{O}\text{---}\text{N}\text{---}\text{NPh}$  are therefore assigned to (I) and (II), respectively. Similar but very unstable compounds appear to be derived from  $\text{HCO}\cdot\text{NH}_2$  and  $\text{PhN}_2\text{Cl}$ . H. W.

***p*-Iodophenol.** F. B. DAINS and F. EBERLY (Org. Syntheses, 1935, 15, 39—40).— $p\text{-OH}\cdot\text{C}_6\text{H}_4\cdot\text{NH}_2$  is diazotised and treated with  $\text{KI}$  and  $\text{Cu}$ .

CH. ABS. (r)

**2:6-Dibromo-4-nitrophenol.** W. W. HARTMAN and J. B. DICKEY (Org. Syntheses, 1935, 15, 6—7).— $p\text{-NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{OH}$  is brominated in  $\text{AcOH}$ .

CH. ABS. (r)

**Photochemical decomposition of nitrated phenols.**—See this vol., 300.

**[Metal]complex chemical behaviour of *o*-aminophenol.** W. HIEBER and A. SCHNACKIG (Z. anorg. Chem., 1936, 226, 209—221).—The following compounds have been prepared with exclusion of air to prevent oxidation of *o*-aminophenol [ $\text{X}=\text{O}\cdot\text{C}_6\text{H}_4\cdot\text{NH}_2$ ,  $\text{Y}=\text{O}\cdot\text{NH}_2\cdot\text{C}_6\text{H}_4\cdot\text{OH}$ ]:  $\text{CoX}_2$ ,  $\text{NiX}_2$ ,  $\text{NiCl}_2\cdot\text{Y}_2$ ,  $\text{CuX}_2$ ,  $\text{ZnX}_2$ ,  $\text{CdCl}_2\cdot\text{Y}_2$ ,  $\text{CdBr}_2\cdot\text{Y}_2$ ,  $\text{CdI}_2\cdot\text{Y}_2$ ,  $\text{CdClX}$ ,  $\text{CdX}_2$ . The existence of  $\text{ZnCl}_2\cdot\text{Y}_2$  has been confirmed. Colour and stability show that the X compounds form internal complexes, metal being co-ordinated with N; the Y compounds, on the other hand, behave as additive compounds. On treatment of  $\text{ZnCl}_2\cdot\text{Y}_2$  and  $\text{CdCl}_2\cdot\text{Y}_2$  with gaseous  $\text{NH}_3$  almost the whole of Y is replaced. Direct absorption of  $\text{NH}_3$  by  $\text{NiX}_2$  also occurs. Reaction is favoured by the presence of a little moisture. Both types of compound will also take up 2 mols. of  $\text{HCl}$ , with the exception of  $\text{CdClX}$  which takes up 1 mol. Marked colour changes occur. M. S. B.

**Nitration of thymol methyl ether.** A. E. TSCHITSCHIBABIN and M. A. BESTUGEY (Bull. Soc. chim., 1936, [v], 3, 423—424).—1:4:3- $\text{C}_6\text{H}_3\text{MePr}^{\beta}\cdot\text{OMe}$  and 98%  $\text{HNO}_3$  in  $\text{Ac}_2\text{O}$  at  $-2^\circ$  to  $3^\circ$  give poor yields of 2:6-dinitro-3-methoxy-*p*-cymene (I), m.p.  $56^\circ$  (also prepared from the K salt of dinitrothymol and  $\text{KMeSO}_4$  in glycerol at  $180\text{--}200^\circ$ ), and 4:6-dinitro-*m*-cresol Me ether (by replacement of  $\text{Pr}^{\beta}$ ). The odour of (I) is less pleasant than that of “*musc-ambrette*.” H. B.

**[Application of the Friedel-Crafts reaction to methoxydiphenyl ether.]** O. VON SCHICKH (Ber., 1936, 69, [B], 242—244).—Gradual addition of  $\text{AcCl}$  and  $\text{Ph}_2\text{O}$  to sublimed  $\text{AlCl}_3$  gives 4:4'-dichloroacetyldiphenyl ether (I), m.p.  $102^\circ$ , in 43% yield; its constitution is established by its oxidation by  $\text{KMnO}_4$  to 4:4'-dicarboxydiphenyl ether, m.p.  $>285^\circ$ . [Di-*o*-tolyl ether, b.p.  $146\text{--}147^\circ/11\text{ mm.}$ , is oxidised to the corresponding dicarboxylic acid, m.p.  $210\text{--}217^\circ$ . 3:3'-Dicarboxydiphenyl ether has m.p.  $235\text{--}240^\circ$ .] The new group does not invariably occupy the 4 position (if free). The directive influence of OMe for example may override that of the O between the Ph groups. H. W.

**Polycyclic compounds related to the sterols.**

**V. Methoxy- and hydroxy-derivatives of phenanthrene.** G. A. R. KON and F. C. J. RUZICKA (J.C.S., 1936, 187—192).— $\beta$ -4-Methoxy-1-naphthylethyl alcohol, m.p.  $87^\circ$ , obtained from 1:4- $\text{C}_{10}\text{H}_8\text{Br}\cdot\text{OMe}$  and  $(\text{CH}_2)_2\text{O}$ , with  $\text{PBr}_3$  gives the bromide (I), b.p.  $161^\circ/1.2\text{ mm.}$ , which with *Et* cyclopentanone-2-carboxylate yields *Et* 2-( $\beta$ -4-methoxy-1-naphthylethyl)cyclopentanone-2-carboxylate, b.p.  $235\text{--}248^\circ/1.2\text{ mm.}$ , hydrolysed to  $\alpha$ -( $\beta$ -4-methoxy-1-naphthylethyl)adipic acid, m.p.  $178^\circ$ . The acid is pyrolysed to 4-methoxy-1-methylnaphthalene, b.p.  $121^\circ/0.8\text{ mm.}$ , and not to the pentanone. (I) and cyclopentene oxide yield  $\beta$ -4'-methoxy-1'-naphthylethylcyclopentene, b.p.  $150\text{--}160^\circ/0.02\text{ mm.}$  [ $s\text{-C}_6\text{H}_5(\text{NO}_2)_3$  complex, m.p.  $107\text{--}108^\circ$ ], and  $\alpha\delta$ -di-(4-methoxy-1-naphthyl)-butane, m.p.  $124^\circ$ . The pentene and  $\text{P}_2\text{O}_5$  give 9-methoxy-3:4-dihydro-1:2-cyclopentanophenanthrene, b.p.  $185\text{--}186^\circ/0.8\text{ mm.}$  [ $s\text{-C}_6\text{H}_5(\text{NO}_2)_3$  complex, m.p.  $166^\circ$ ]. (I) and 2-methylcyclopentanone afford 2-methyl-1- $\beta$ -4'-methoxy-1'-naphthylethylcyclopentanol, b.p.  $185\text{--}190^\circ/0.1\text{ mm.}$ , and another substance; the carbinol is cyclised to 9-methoxy-1-methyl-3:4-dihydro-1:2-cyclopentanophenanthrene, b.p.  $165\text{--}170^\circ/0.1\text{ mm.}$ , dehydrogenated (Se) to 9-methoxy-1:2-cyclopentanophenanthrene, m.p.  $129^\circ$  [picrate, m.p.  $124^\circ$ ;  $s\text{-C}_6\text{H}_5(\text{NO}_2)_3$  complex, m.p.  $132^\circ$ ], trinitrotoluene complex, m.p.  $105\text{--}106^\circ$ ]. The following are similarly obtained: 2:5-dimethyl-1- $\beta$ -4'-methoxy-1'-naphthylethylcyclopentanol, b.p.  $195\text{--}200^\circ/0.2\text{ mm.}$ , 9-methoxy-1:3'-dimethyl-3:4-dihydro-1:2-cyclopentanophenanthrene, b.p.  $180\text{--}183^\circ/0.3\text{ mm.}$  [picrate, m.p.  $119\text{--}120^\circ$ ;  $s\text{-C}_6\text{H}_5(\text{NO}_2)_3$  complex, m.p.  $140\text{--}141^\circ$ ], and 9-methoxy-3'-methyl-1:2-cyclopentanophenanthrene, m.p.  $111^\circ$  (picrate, m.p.  $147^\circ$ ). 1:5- $\text{C}_{10}\text{H}_8\text{Br}\cdot\text{OMe}$  and  $(\text{CH}_2)_2\text{O}$  give  $\beta$ -5-methoxy-1-naphthylethyl alcohol, m.p.  $53\text{--}54^\circ$  [with excess of  $(\text{CH}_2)_2\text{O}$ , a product,  $\text{C}_{13}\text{H}_{10}\text{O}_5$ , m.p.  $128^\circ$ , is obtained], converted ( $\text{PBr}_3$ ) into the bromide (II), b.p.  $180^\circ/1.7\text{ mm.}$  The bromide similarly gives 2-methyl-1-( $\beta$ -5-

*methoxy-1'-naphthylethyl*cyclopentanol, b.p. 190—195°/0.1 mm., and  $\alpha$ -di-(5-methoxy-1-naphthyl)butane, m.p. 176°. The carbinol is dehydrated to 8-methoxy-1-methyl-3:4-dihydro-1:2-cyclopentanophenanthrene, b.p. 185°/0.3 mm., dehydrogenated to 8-methoxy-1:2-cyclopentenophenanthrene, m.p. 153° [picrate, m.p. 160°;  $s\text{-C}_6\text{H}_3(\text{NO}_2)_3$  complex, m.p. 194°]. (II), Et malonate, and K give an ester, hydrolysed to  $\beta$ -5-methoxy-1-naphthylethylmalonic acid, m.p. 182° (decomp.), decarboxylated to  $\gamma$ -5-methoxy-1-naphthylbutyric acid, m.p. 143°. Cyclisation of this acid with  $\text{SOCl}_2$  affords a compound,  $\text{C}_{15}\text{H}_{14}\text{O}_2$ , m.p. 88—89°, which does not form a semicarbazone and is demethylated to a substance,  $\text{C}_{14}\text{H}_{14}\text{O}_3$ , m.p. 155°; cyclisation with  $\text{SnCl}_4$  yields 1-keto-8-methoxy-1:2:3:4-tetrahydrophenanthrene, m.p. 137°, demethylated to the hydroxy-ketone, m.p. 256°. (I), Et malonate, and Na yield an ester, b.p. 210°/3—5 mm., hydrolysed to  $\beta$ -4-methoxy-1-naphthylethylmalonic acid, m.p. 180° (decomp.), decarboxylated to  $\gamma$ -4-methoxy-1-naphthylbutyric acid, m.p. 131°. The acid is cyclised ( $\text{AlCl}_3$ ) to 1-keto-9-methoxy-1:2:3:4-tetrahydrophenanthrene, m.p. 98°, demethylated to the hydroxy-ketone, m.p. 260°. F. R. S.

**2-Hydroxyphenanthrene in coal tar.** O. KRUBER (Ber., 1936, 69, [B], 246—247).—The isolation of 2-hydroxyphenanthrene, m.p. 168—169°, from a coal-tar fraction, b.p. 398—404°, is described. The "acid oil" content of the fraction is low in comparison with that of fractions of somewhat lower b.p.; pitch probably contains still less phenols.

H. W.

**Diastereoisomeric naphthalene-1:5-disulphonylacetic acids. Equivalence of the 1:5-positions in naphthalene.** F. GAJOWCZYK and J. SZUSZKO (Bull. Acad. Polonaise, 1935, A, 349—359).—Oxidation of Et naphthalene-1:5-dithioglycollate (I) (Corbellini *et al.*, A., 1931, 748) with  $\text{H}_2\text{O}_2$ -AcOH at room temp. affords *Et i-naphthalene-1:5-dithionylacetate*,  $\text{CO}_2\text{Et}\cdot\text{CH}_2\cdot\text{SO}\cdot\text{C}_{10}\text{H}_6\cdot\text{SO}\cdot\text{CH}_2\cdot\text{CO}_2\text{Et}$ , m.p. 168° (decomp.) (less sol. in  $\text{C}_6\text{H}_6$ ), hydrolysed to the free *i-acid*, m.p. 235° (decomp.) [brucine, m.p. 179° (decomp.),  $[\alpha]_D^{20} -8.9^\circ$  in  $\text{CHCl}_3$ , quinine, m.p. 204° (decomp.),  $[\alpha]_D^{20} -139^\circ$  in  $\text{EtOH}\cdot\text{CHCl}_3$ , and cinchonine, decomp. 175°,  $[\alpha]_D^{20} -96.6^\circ$  in  $\text{EtOH}\cdot\text{CHCl}_3$ , salts], and, from the mother-liquor, the  $\text{C}_6\text{H}_6$ -sol. *Et dl-naphthalene-1:5-dithionylacetate*, m.p. 153° (decomp.), hydrolysed to the *dl-acid*, m.p. 125° (decomp.). This is resolved by fractional crystallisation of its quinine salt from  $\text{COME}_2$  into (+)-, m.p. 125—126° (decomp.),  $[\alpha]_D^{20} +511^\circ$  in 1% NaOH [quinine salt, m.p. 158° (decomp.),  $[\alpha]_D^{20} +61.2^\circ$  in  $\text{EtOH}\cdot\text{CHCl}_3$ ] and from the mother-liquor, or better by fractionation of the brucine salt, (—)-*naphthalene-1:5-dithionylacetic acid*, m.p. 124—125° (decomp.),  $[\alpha]_D^{20} -495.7^\circ$  in 1% NaOH [brucine salt, m.p. 187—188° (decomp.),  $[\alpha]_D^{20} -183.8^\circ$  in  $\text{EtOH}\cdot\text{CHCl}_3$ ]. The existence of a *dl*- and *i*-form proves the equivalence of the 1:5 positions in  $\text{C}_{10}\text{H}_8$ , which must possess a centre of symmetry. Oxidation of (I) with excess of  $\text{H}_2\text{O}_2$  at 70° affords the *Et* ester, m.p. 158°, of *naphthalene-1:5-disulphonylacetic acid*, m.p. about 300° (decomp.), which is obtained by hydrolysis. J. W. B.

**Salt-forming properties of halogens. Reaction of univalent positive halogen compounds with unsaturated hydrocarbons.** M. I. USCHAKOV, V. O. TSCHISTOV, and M. A. SCHLOSBERG (J. Gen. Chem. Russ., 1935, 5, 1391—1398).—Suspensions of Ag salts of different acids in  $\text{CCl}_4$  react with I or Br as follows:  $\text{R}\cdot\text{OAg} + \text{X}_2 = \text{R}\cdot\text{OX} + \text{AgX}$ . Substances possessing the  $\cdot\text{C}\cdot\text{C}\cdot$  group react with  $\text{R}\cdot\text{OX}$  to yield compounds of the general type  $\cdot\text{CX}\cdot\text{COR}$ . The following substances have been prepared in this way: from cyclohexene: iodo-cyclohexyl benzoate, m.p. 54.5—56°; bromo-, m.p. 64—64.5°, and chloro-, b.p. 168—195°/14 mm., -cyclohexylbenzoate; iodo-, m.p. 92.3°, and bromo-, m.p. 81.5°, -cyclohexyl *m*-nitrobenzoate; bromocyclohexyl acetate, b.p. 108—111°/17 mm., propionate, b.p. 118.5°/6 mm., *n*-butyrate, b.p. 138°/8 mm., and isovalerate, b.p. 141—142°/9 mm.; chlorocyclohexyl nitrate, b.p. 108—109°/13 mm.; from  $\text{C}_2\text{H}_4$ :  $\beta$ -bromoethyl acetate, b.p. 159—164°, and nitrate, b.p. 81.5°/43 mm.; from  $\text{CHMe}\cdot\text{CH}_2$ :  $\beta$ -bromoisopropyl acetate, b.p. 161—165°/750 mm., and benzoate, b.p. 152°/15 mm.; from styrene:  $\beta$ -chloro- $\alpha$ -phenylethyl nitrate, b.p. 107°/4 mm. R. T.

**Configurative relationship of methylcyclohexylcarbinol to methylhexylcarbinol.** P. A. LEVENE and S. A. HARRIS (J. Biol. Chem., 1935, 113, 55—59).—Et (—)- $\alpha$ -methoxypropionate is transformed by  $\text{Mg}_2$  pentamethylene dibromide into (+)-1-*z*-methoxyethylcyclohexanol, b.p. 99—104°/22 mm.,  $[\alpha]_D^{20} +7.65^\circ$ , which is not decomposed at about 205° and yields ill-defined products when distilled with  $\text{KHSO}_4$ . When treated with K in anhyd.  $\text{Et}_2\text{O}$  followed by  $\text{CS}_2$  and MeI and then distilled it gives (—)-1-*z*-methoxyethyl- $\Delta^1$ -cyclohexene, b.p. 168—171°,  $[\alpha]_D^{20} -12.43^\circ$  readily hydrogenated (Adams) in AcOH but not in  $\text{C}_5\text{H}_{12}$  to (+)- $\alpha$ -methoxyethylcyclohexane (I), b.p. 168—171°,  $[\alpha]_D^{20} +2.93^\circ$ . Synthetic (I) has  $[\alpha]_D^{20}$  b.p. 170—171°,  $[\alpha]_D^{20} +7.90^\circ$ . The configurative relationship of *d*-methyl-*n*-hexylcarbinol to (I) is therefore established by chemical methods (cf. A., 1932, 1027—1028). H. W.

**Reduction of the  $\cdot\text{CH}(\text{OH})\cdot\text{CCl}_3$  grouping.** A. N. MELDRUM and A. S. DATAR (Proc. Indian Acad. Sci., 1935, 2, A, 580—583).—This grouping in compounds of type  $\text{NRR}\cdot\text{C}_6\text{H}_4\cdot\text{CH}(\text{OH})\cdot\text{CCl}_3$  (obtained by condensing amines with  $\text{CCl}_3\cdot\text{CHO}$  at room temp. or at 50°) is reduced by  $\text{Zn}\cdot\text{AcOH}$  to  $\cdot\text{CH}_2\cdot\text{CHCl}_2$ . The following are prepared. *N*-Methyl- (I), m.p. 77° (Bz derivative, m.p. 130°), *N*-ethyl- (II), m.p. 73° (Bz derivative, m.p. 75°), *NN*-dimethyl-, m.p. 76° (picrate, m.p. 138°), *NN*-diethyl- (picrate, m.p. 140°), and *N*-benzyl-*N*-methyl- (picrate, m.p. 132°) [from  $\alpha$ -*p*-benzylmethylaminophenyl- $\beta\beta\beta$ -trichloroethyl alcohol, m.p. 85° (decomp.) (hydrochloride, decomp. 150°)] -*p*-( $\beta\beta$ -dichloroethyl)aniline. The *NO*-derivative of (I), m.p. 87°, is reduced by Zn in  $\text{EtOH}\cdot\text{AcOH}$  to  $\alpha$ -methyl- $\alpha$ -*p*-( $\beta\beta$ -dichloroethyl)phenylhydrazine hydrochloride (corresponding  $\text{PhCHO}$ , m.p. 150°, and glucose-, m.p. 165°, -phenylhydrazones); the *NO*-derivative of (II), m.p. 50°, gives the similar  $\alpha$ -ethyl-compound (corresponding  $\text{PhCHO}$ -phenylhydrazone, m.p. 110°). E. W. W.

***p*-Butylsaligenin.** R. V. RICE and W. C. HARDEN (J. Amer. Pharm. Assoc., 1936, 25, 7—9).— $\text{Pr}\cdot\text{CO}_2\text{H}$

treated with  $\text{SOCl}_2$  followed successively by  $\text{PhOH}$  and  $\text{AlCl}_3$  yields on fractional distillation  $p\text{-OH}\cdot\text{C}_6\text{H}_4\cdot\text{COPr}^a$ , reduced ( $\text{Zn-HCl}$ ) to  $p\text{-C}_6\text{H}_4\text{Bu}^a\cdot\text{OH}$  (*phenylurethane*, m.p.  $113^\circ$ ), which affords (Reimer-Tiemann) 5-butylsalicylaldehyde, reduced (Adams) to *p-butylsaligenin*, m.p.  $81^\circ$ . F. O. H.

**Liquid crystals of some cholesterol compounds.** P. GAUBERT (Compt. rend., 202, 141—143).—The following compounds melted with cholesterol may give liquid crystals: resorcinol, pyrocatechol, phloroglucinol, pyrogallol, *p*-nitrophenol, saligenin, erythritol, phloridzin, saccharin, isosaccharin, rhamnose, nitrophthalic acid, and agaricic acid. The products are most easily obtained with equimol. proportions of the two components. Especially if quickly cooled, they may pass to a solid form preserving their optical anisotropy but gradually increasing in hardness. The melting of such hardened products is described.

B. W. R.

**Liebermann-Burchard reaction velocities of sterols.** I. Difference between free and ester cholesterol applied to the determination of cholesteryl esters. II. Test for coprostenol in plasma. J. G. REINHOLD (Amer. J. Med. Sci., 1935, 189, 302—303, 303).—I. Cholesteryl esters (I) and coprostenol (*allocholesterol*) develop colour with  $\text{Ac}_2\text{O}$  and  $\text{H}_2\text{SO}_4$  more rapidly than does cholesterol (II). The difference is more marked at low temp. and with dil.  $\text{H}_2\text{SO}_4$ , and disappears with high temp. and much acid. The Liebermann-Burchard reaction at  $0^\circ$  in presence of 0.025 c.c. of  $\text{H}_2\text{SO}_4$  determines (I), a small correction being necessary for free (II). At  $38^\circ$  the total (II) is recorded.

II. Coprostenol is determined as (I). None occurs in plasma.

CH. ABS. (p)

**Sexual hormones. XII. Amines of the androsterone series.** L. RUZICKA and M. W. GOLDBERG (Helv. Chim. Acta, 1936, 19, 107—108).—Androsteroneoxime is reduced by Na and boiling  $\text{EtOH}$  to *cis*-17-amino-3-hydroxyandrostane, m.p.  $187\text{--}188^\circ$  (hydrochloride, m.p. about  $365^\circ$  after much decomp.). Similarly *trans*- $\Delta^{5:6}$ -dehydroandrosterone gives *trans*- $\Delta^{5:6}$ -17-amino-3-hydroxyandrostene, m.p.  $160\text{--}162^\circ$  [hydrochloride, m.p. about  $300^\circ$  (decomp.)]. Physiologically these compounds are much less active than the corresponding 17-OH-derivatives.

H. W.

**Combined oestriol in human pregnancy urine.**—See this vol., 503.

**Colourless compounds which accompany carotenoids in plants.**—See this vol., 533.

**Catalytic reduction of aromatic carboxylic esters.** See this vol., 436.

**Hydrolysis of substituted benzoic esters.**—See this vol., 432.

**Preparation of calcium or ammonium salts of iodoxybenzoic acid.** F. R. GREENBAUM (Amer. J. Pharm., 1936, 108, 17—22).—Very pure Ca *o*-iodoxybenzoate, free from the corresponding I- and IO-compounds and Cl, is obtained in excellent yield by oxidising *o*- $\text{C}_6\text{H}_4\text{I}\cdot\text{CO}_2\text{H}$  (prep. described) in dil.  $\text{H}_2\text{SO}_4$  suspension with  $\text{KBrO}_3$  at  $85^\circ$ . The crude acid is extracted with hot  $\text{EtOH}$ , dissolved in

$\text{NH}_3$  solution, decolorised with C, and pptd. as the Ca salt with  $\text{CaCl}_2$ . S. C.

**Halogenosulphobenzoic acids.** M. POLACZEK (Rocz. Chem., 1935, 15, 578—582).—The position of the  $\text{SO}_3\text{H}$  of 2-bromo- ( $\text{Ph}_2$  ester, m.p.  $125\text{--}126^\circ$ ) and 2-chloro- (I) ( $\text{Ph}_2$  ester) -5-sulphobenzoic acid has been established by conversion into 5-sulphosalicylic acid (II) by hydrolysis with 10% aq.  $\text{K}_2\text{CO}_3$  at  $170^\circ$ , and comparison of its  $\text{Ph}_2$  ester with that from synthetically prepared (II). (II) is obtained in 93% yield from *o*- $\text{C}_6\text{H}_4\text{Cl}\cdot\text{CO}_2\text{H}$  and 20% oleum ( $100^\circ$ ; 3 hr.). R. T.

**Preparation of 2-chloro-4-nitrobenzoic acid.** A. ALBERT and W. H. LINNELL (J.S.C.I., 1936, 55, 54r).—In converting 4-nitro-*o*-toluidine (I) into *o*-chloro-*p*-nitrotoluene (II) by the Sandmeyer reaction, max. yields are realised only under carefully controlled experimental conditions. The by-products are 3:3'-dinitro-6:6'-dimethylazobenzene and 3:3'-dinitro-6:6'-dimethyldiphenyl. The oxidation of (II) to 2-chloro-4-nitrobenzoic acid (III) by  $\text{K}_2\text{Cr}_2\text{O}_7$  proceeds best with 1.3 equivs. of the latter. Several unrecorded properties of (III) are given. The yields by this process are compared with those obtained by acetylating (I), oxidising with  $\text{KMnO}_4$ , and then applying the Sandmeyer reaction. The identity of the 1:2:4-nitroanthranilic acid obtained as an intermediate with the so-called "1:2:5"-nitroanthranilic acid of Ullmann is shown, and a no. of unrecorded properties are given. The reactions (I)  $\rightarrow$  (III) gave lower yields in the case of the analogous Br-compounds.

**Organic reactions with boron fluoride. XII. Preparation of esters of aromatic acids.** F. J. SOWA and J. A. NIEUWLAND (J. Amer. Chem. Soc., 1936, 58, 271—272).— $\text{C}_6\text{H}_4\text{R}\cdot\text{CO}_2\text{Alk}$  are formed when  $\text{C}_6\text{H}_4\text{R}\cdot\text{CO}_2\text{H}$  and  $\text{AlkOH}$  are heated with  $\text{BF}_3$  (amount for max. yield varies with R) or  $\text{BF}_3\cdot\text{Et}_2\text{O}$ ; in general, esterification occurs less readily than with  $\text{AlkCO}_2\text{H}$  (A., 1932, 728). The following are prepared: Me, Pr<sup>*β*</sup>, Bu<sup>*α*</sup>, Bu<sup>*β*</sup>, and *sec*-Bu benzoates; *p*- $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CO}_2\text{Me}$ ; *o*- and *p*- $\text{NH}_2\cdot\text{C}_6\text{H}_4\cdot\text{CO}_2\text{Me}$ ; *o*- $\text{C}_6\text{H}_4\text{Cl}\cdot\text{CO}_2\text{Me}$ ; *o*- $\text{OH}\cdot\text{C}_6\text{H}_4\cdot\text{CO}_2\text{Me}$ ; *o*- $\text{OH}\cdot\text{C}_6\text{H}_4\cdot\text{CO}_2\text{Bu}^\beta$ . Bu<sup>*γ*</sup>OBz is not preparable.

H. B.

**$\gamma$ -Phenylbutyric acid.** S. C. OVERBAUGH, C. F. H. ALLEN, E. L. MARTIN, and L. F. FIESER (Org. Syntheses, 1935, 15, 64—66).— $\text{CH}_2\text{Bz}\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$  is reduced with Zn and HCl. CH. ABS. (r)

**Asymmetric carbon atom CHDR'R". I. Constitution of a deuterio- $\beta$ -phenylpropionic acid from cinnamic acid and deuterium.** H. ERLMEYER and H. GÄRTNER (Helv. Chim. Acta, 1936, 19, 145—148).—Treatment of  $\text{CHPh}\cdot\text{CH}\cdot\text{CO}_2\text{H}$  with nascent D causes complete replacement of H by D.  $\text{Al}_2\text{S}_3$  and  $\text{D}_2\text{O}$  gives  $\text{D}_2\text{S}$ , transformed by I in  $\text{D}_2\text{O}$  into DI which, in presence of red P, converts  $\text{CHPh}\cdot\text{CH}\cdot\text{CO}_2\text{H}$  into  $\text{C}_6\text{H}_2_{18}\text{D}_{282}\cdot\text{C}_2\text{H}_{162}\text{D}_{238}\cdot\text{CO}_2\text{H}$  (I) which passes when treated with Br and subsequently heated into  $\text{C}_6\text{H}_2_{18}\text{D}_{282}\cdot\text{C}_2\text{H}_0_{74}\text{D}_{126}\cdot\text{CO}_2\text{H}$  and is oxidised by  $\text{KMnO}_4$  to  $\text{C}_6\text{H}_2_{18}\text{D}_{282}\cdot\text{CO}_2\text{H}$ . Attempts to resolve (I) into its optical antipodes have been unsuccessful. H. W.

**Condensation of esters of unsaturated acids with carbamide.** II. Z. JERZMANOWSKA-SIENKIEWICZOWA (Rocz. Chem., 1935, 15, 510—515).—CHPh·CH·CO<sub>2</sub>Et and CO(NH<sub>2</sub>)<sub>2</sub> (I) in EtOH in presence of NaOEt yield cinnamoylcarbamide (II) or cinnamamide (III), according to the conditions of the experiment. (II) affords cinnamic acid and (III) when heated with EtOH-NaOEt or MeOH-KOH, cyanuric acid and (III) when heated alone at 210—220°, and 6-phenyldihydrouracil when fused with (I) (180—185°; 2.5 hr.). Fumaric acid and (I) (135—140°; 2.5 hr.) yield biuret, triuret, and hydantoin-5-acetic acid. R. T.

**o-Phenylpentadecic and  $\chi$ -phenylbehenic acids.** G. M. HILLS and R. ROBINSON (J.C.S., 1936, 281—283).—Condensation of Et sodio- $\nu$ -keto- $\mu$ -carboethoxymyristate and CH<sub>2</sub>Ph·CH<sub>2</sub>Cl and subsequent hydrolysis by 5% H<sub>2</sub>SO<sub>4</sub> and then by 3.5% aq. KOH leads to  $\nu$ -ketomyristic acid (46%; Et ester, b.p. 145—160°/0.5 mm., m.p. 28—29°), and  $\nu$ -keto-o-phenylpentadecic acid (20%), m.p. 76—77° [semi-carbazone, m.p. 87—88°; Et ester (crude), m.p. 33—35°], reduced (Clemmensen) to o-phenylpentadecic acid, (I), m.p. 60—61°.  $\kappa$ -Phenyldecoyl chloride, b.p. 204°/14 mm. (decomp.) (anilide, m.p. 71—72°; gives the Et ester, b.p. 199°/13 mm.), leads similarly to  $\nu$ -keto- $\chi$ -phenylbehenic acid, m.p. 81°, reduced to  $\chi$ -phenylbehenic acid (II), m.p. 81° (Et ester, m.p. 53°). (I) and (II) cannot be injected and are unchanged when fed to rabbits. R. S. C.

**Chemical constitution and local anæsthetic action of alkamine esters of  $p$ -alkoxybenzoic acids.** C. ROHMANN and B. SCHEURLE (Arch. Pharm., 1936, 274, 110—126).—

$p$ -OR·C<sub>6</sub>H<sub>4</sub>·CO<sub>2</sub>·CH<sub>2</sub>·CH<sub>2</sub>Cl (I) (usually prepared from OR·C<sub>6</sub>H<sub>4</sub>·COCl and CH<sub>2</sub>Cl·CH<sub>2</sub>·OH) and NHET<sub>2</sub> at 110° give  $p$ -OR·C<sub>6</sub>H<sub>4</sub>·CO<sub>2</sub>·CH<sub>2</sub>·CH<sub>2</sub>·NET<sub>2</sub> [isolated as the hydrochlorides (II)], which are local anæsthetics. The influence of R on the activity is Me < Et < H < Pr < Bu, isoamyl; Pr<sup>a</sup> and Bu<sup>a</sup> impart more activity than Pr<sup>b</sup> and Bu<sup>b</sup>. Introduction of NET<sub>2</sub> into R causes diminished activity. Increase in length of the alkamine group and introduction of Alk in the 3 position cause increased activity. The following are described: (I) R=H, m.p. 110°, Me, Et, m.p. 46°, Bu<sup>a</sup>, m.p. 32°; (II) R=H, m.p. 183°, Me, m.p. 146°, Et, m.p. 174°, Pr<sup>a</sup>, m.p. 137°, Pr<sup>b</sup>, m.p. 128°, Bu<sup>a</sup>, m.p. 147°, Bu<sup>b</sup>, m.p. 131°, isoamyl, m.p. 128°, allyl, m.p. 130° (lit. 193°) [from  $p$ -C<sub>3</sub>H<sub>5</sub>O·C<sub>6</sub>H<sub>4</sub>·CO<sub>2</sub>H (1 mol.), NET<sub>2</sub>·CH<sub>2</sub>·CH<sub>2</sub>Cl (III) (1 mol.), and EtOH-NaOEt (2 mols.)], and  $\beta$ -diethylaminoethyl, m.p. 180° [from  $p$ -OH·C<sub>6</sub>H<sub>4</sub>·CO<sub>2</sub>H and (III) in EtOH-NaOEt].  $\gamma$ -Diethylaminopropyl  $p$ -ethoxybenzoate hydrochloride, m.p. 148°, is prepared from  $p$ -OEt·C<sub>6</sub>H<sub>4</sub>·COCl and Cl[CH<sub>2</sub>]<sub>3</sub>·OH followed by NHET<sub>2</sub>.  $\varepsilon$ -Diethylaminoamyl anisate,  $p$ -ethoxybenzoate, and  $p$ -butoxybenzoate hydrochlorides, m.p. 131°, 82—83°, and 56°, respectively, are obtained from  $p$ -OR·C<sub>6</sub>H<sub>4</sub>·CO<sub>2</sub>Na and (CH<sub>2</sub>)<sub>5</sub>Br<sub>2</sub> followed by NHET<sub>2</sub>. Me  $p$ -allyloxybenzoate rearranges at 220—250° into Me 4-hydroxy-3-allylbenzoate, converted by Pr<sup>a</sup>Br and KOH in COMeEt followed by hydrolysis (10% NaOH) into 4-propoxy-3-allylbenzoic acid, m.p. 138°, which with

(III) in EtOH-NaOEt gives the  $\beta$ -diethylaminoethyl ester (hydrochloride, m.p. 103°). H. B.

**Aminohydroxy-acids and their degradation in the animal body.** F. KNOOP, F. DITT, W. HECKSTEDEN, J. MAIER, W. MERZ, and R. HÄRLE (Z. physiol. Chem., 1936, 239, 30—46).— $\alpha$ -Amino- $\beta$ -hydroxy-acids (I) are not degraded in the same manner as simple NH<sub>2</sub>-acids, but are transformed by  $\beta$ -oxidation into N-free acids containing fewer C.  $\alpha$ -Amino- $\beta$ -keto-acids, presumably intermediate products of the degradation of (I), have a very high redox potential, much > that of ascorbic acid. CH<sub>2</sub>Ph·CO·CH<sub>2</sub>·CO<sub>2</sub>Et is transformed by PhN<sub>2</sub>Cl and NaOAc in EtOH-H<sub>2</sub>O into the corresponding phenylhydrazone, C<sub>18</sub>H<sub>18</sub>O<sub>3</sub>N<sub>2</sub>, m.p. 67°, which is converted by hydrogenation (Pd-C in 5% HCl-EtOH followed by Pt-Fe in H<sub>2</sub>O) and subsequent hydrolysis into  $\alpha$ -amino- $\beta$ -hydroxy- $\gamma$ -phenylbutyric acid, decomp. 259° (Bz<sub>1</sub> derivative, decomp. 181°); (?) 2:5-dibenzyl-3:6-dihydropyrazine, m.p. 75—76°, is formed as by-product. CH<sub>2</sub>Ph·CH<sub>2</sub>·CHO and CH<sub>2</sub>(CO<sub>2</sub>H)<sub>2</sub> are condensed in C<sub>5</sub>H<sub>5</sub>N at 90° and the Na salt of the resulting acid, m.p. 103—104°, is transformed by Br into  $\alpha$ -bromo- $\beta$ -hydroxy- $\delta$ -phenyl-n-valeric acid, m.p. 94—95°. The corresponding Et ester, b.p. 157—163°/0.5 mm., is transformed by NaN<sub>3</sub> in EtOH-H<sub>2</sub>O into the azido-ester, decomp. 100°/high vac., which is hydrolysed and then reduced (PtO<sub>2</sub> in anhyd. EtOAc) to  $\alpha$ -amino- $\beta$ -hydroxy- $\delta$ -phenyl-n-valeric acid, decomp. 246° (Bz<sub>1</sub> derivative, decomp. 196°). The Bz derivative, m.p. 175—176°, and the hydantoin, m.p. 191—193°, of hydroxyglutamic acid are described.  $\alpha$ -NH<sub>2</sub> and  $\alpha$ -OH-acids react with Pb(OAc)<sub>4</sub> in AcOH at 60—70° with loss of CO<sub>2</sub> and according to the principle of Criegee's glycol fission. Introduction of acyl into NH<sub>2</sub> or OH inhibits the reaction. Criegee's assumption that the method permits diagnosis of the groups ·NH·CH·CO<sub>2</sub>H is therefore too general. After acylation, therefore, serines and isoserines can be distinguished from one another by Criegee's method. H. W.

**Iodination of nitrotyrosine.** H. BAUER and E. STRAUSS (Ber., 1936, 69, [B], 245—246; cf. A., 1935, 1122).—Slow passage of ICl vapour into a solution of  $l$ -tyrosine in dil. HCl at 10° gives 3:5-diiodotyrosine, decomp. 194°. Nitrotyrosine hydrochloride is converted similarly into 5-iodo-3-nitrotyrosine. H. W.

**Synthesis of certain alkeines derived from mandelic and tropic acids.** E. PŁĄZEK and Z. RODEWALD (Rocz. Chem., 1935, 15, 481—490).—The cyanohydrin obtained from CPhMe in Et<sub>2</sub>O, AcOH, and KCN at 0° yields when heated with HCl (130°; 3 hr.) CH<sub>2</sub>Cl·CHPh·CO<sub>2</sub>H, the Me ester, b.p. 93°/0.4 mm., of which affords Me  $\beta$ -ethoxy- $\alpha$ -phenylpropionate (O-ethyltropate) (I), b.p. 98—100°/0.3 mm., when treated with NaOEt in EtOH. The acid has b.p. 132—134°/0.1 mm. (chloride, b.p. 88—89°/0.6 mm.; dimethylaminoethyl ester, b.p. 110—112°/0.1 mm.).  $\beta$ -Propoxy- $\alpha$ -phenylpropionic acid, b.p. 135—137°/0.15 mm. (chloride, b.p. 96—97°/0.3 mm.; Me ester, b.p. 108°/0.1 mm.; dimethylaminoethyl ester, b.p. 113°/0.1 mm.), is obtained analogously. Tropyl, b.p. 169—171°/0.4

mm. (picrate, m.p. 216—217°; picrolonate, m.p. 155—156°), and dimethylaminoethyl, b.p. 108—110°/0.2 mm. (picrolonate of methiodide, m.p. 139°),  $\alpha$ -ethoxy- $\alpha$ -phenylacetate (O-ethylmandelate) have been prepared from the appropriate alcohols and ethoxy-phenylacetyl chloride, b.p. 84—85°/0.4 mm.; tropyl, b.p. 170—172°/0.4 mm. (picrate, m.p. 106°; picrolonate, m.p. 164°), and dimethylaminoethyl, b.p. 110—112°/0.2 mm. (picrate of methiodide, m.p. 162°), O-propylmandelate were obtained similarly from propoxyphenylacetyl chloride, b.p. 85—86°/0.8 mm.

R. T.

Manufacture of arylamides of 2-hydroxydiphenyl-3-carboxylic acid and of azo-dyes therefrom.—See B., 1936, 229.

**Abnormal strength of 2:6-dihydroxybenzoic acids.** W. BAKER (Nature, 1936, 137, 236).—The increased acidity of salicylic acid and its derivatives over that of BzOH and other hydroxybenzoic acids is probably due to chelation of the anion, which would hinder return of the proton and hence increase dissociation. By analogy with 2-nitroresorcinol, it is suggested that an ionised  $\text{CO}_2\text{H}$  can chelate with two o-OH groups.

L. S. T.

**Decomposition of phenolic ethers. III.** Thermal decomposition of piperonylic acid in presence of sand, acid clay, or active carbon. K. ONO and M. IMOTO (J. Chem. Soc. Japan, 1935, 56, 347—352).—When heated with the above catalysts at 260—280°/130—135 mm., piperonylic acid yields o- $\text{C}_6\text{H}_4(\text{OH})_2$  and a little pyrocatechol Me ether.

CH. ABS. (r)

**Veratronitrile (3:4-dimethoxybenzonitrile).** J. S. BUCK and W. S. IDE (Org. Syntheses, 1935, 15, 85—86).—3:4-(OMe) $_2\text{C}_6\text{H}_3\cdot\text{CHO}$  is converted into the oxime, which is then dehydrated with  $\text{Ac}_2\text{O}$ .

CH. ABS. (r)

**Homoveratric acid.** H. R. SNYDER, J. S. BUCK, and W. S. IDE (Org. Syntheses, 1935, 15, 31—34).—The prep. is described in detail.

CH. ABS. (r)

**Stability of aqueous solutions of potassium hydrogen phthalate.** I. HOFFMAN (J. Res. Nat. Bur. Stand., 1935, 15, 583—584).—1% aq. K H phthalate solution is permanently stable under laboratory conditions.

J. S. A.

**Rabbits bile. I.  $\alpha$ - and  $\beta$ -Lagodeoxycholic acid and lithocholic acid.** S. KISHI (Z. physiol. Chem., 1936, 238, 210—220).—From the bile there have been isolated  $\alpha$ -lagodeoxycholic acid (I),  $\text{C}_{24}\text{H}_{40}\text{O}_4$ , m.p. 156—157°,  $[\alpha]_D^{25} + 80.21^\circ$  in 90% EtOH [Ba salt; Me ester, m.p. 107—108°,  $[\alpha]_D^{25} + 73.97^\circ$  in 90% EtOH; Et ester, m.p. 135°; formyl derivative (II), m.p. 202°; Me ester of (II), m.p. 103—104°; acetate (III), m.p. 188—189°; Me ester of (III), m.p. 144°],  $\beta$ -lagodeoxycholic acid (IV), m.p. 213°,  $[\alpha]_D^{25} + 37.43^\circ$  in 95% EtOH (Me ester, m.p. 175°; Et ester, m.p. 172°,  $[\alpha]_D^{25} + 34.05^\circ$  in 90% EtOH), and lithocholic acid. (I) gives dehydrodeoxycholic acid when oxidised with  $\text{CrO}_3$  in AcOH and deoxybiliary acid when oxidised with  $\text{HNO}_3$ . Heated at 320°/about 12 mm. and distilled in a high vac. (I) gives a choladienic acid, m.p. 135—137°, which with  $\text{H}_2\text{-PtO}_2$  gives cholanolic acid. (IV) with  $\text{CrO}_3$  in

AcOH gives a dehydro-acid, m.p. 222—223°,  $[\alpha]_D^{25} + 87.21^\circ$  in 90% EtOH (Me ester, m.p. 136—138°).

W. McC.

**Fused rings. I.** P. C. MITTER and D. K. BANERJI (Ber., 1936, 69, [B], 456—458).—Et 2-methylcyclopentan-1-one-2-carboxylate,  $\text{CO}_2\text{Et}\cdot\text{CHBr}\cdot\text{CH}_2\cdot\text{CO}_2\text{Et}$ , and Zn wool activated by I in anhyd.  $\text{C}_6\text{H}_6$  give a mixture of unsaturated and OH-ester transformed by  $\text{P}_2\text{O}_5$  in boiling  $\text{C}_6\text{H}_6$  into the unsaturated ester,  $\text{C}_{17}\text{H}_{26}\text{O}_6$ , b.p. 176—178°/3 mm., which is hydrogenated ( $\text{PtO}_2\text{-EtOH}$ ) to Et $_2$  2-carbethoxy-2-methylcyclopentylsuccinate (I), b.p. 173—175°/4 mm. (I) with Na in boiling  $\text{C}_6\text{H}_6$  affords Et $_2$  7-methyldicyclo-[0:3:3]-octan-1-one-2:3-dicarboxylate, b.p. 150—178°/3 mm. (slight decomp.) (semicarbazone, m.p. 195°), hydrolysed by KOH-EtOH to the corresponding non-cryst. acid, which slowly yields a semicarbazone, decomp. 198—200°.

H. W.

**Thermal decomposition of the silver salts of carboxylic acids. II. Experimental evidence of the reaction mechanism.** S. J. KANEVSKAJA, M. M. SCHEMJAKIN, and E. M. BANDASS-SCHEMJAKINA (Ber., 1936, 69, [B], 257—265; cf. A., 1934, 1219).—Isolation of intermediate products and their behaviour when heated with  $\text{Ag}_2\text{O}$  shows that thermal decomp. of the Ag salts of aldehydocarboxylic acids follows the course:  $2\text{CHO}\cdot\text{R}^{\text{II}}\cdot\text{CO}_2\text{Ag} \rightarrow$

$\text{R}^{\text{I}}\cdot\text{CHO} + \text{CO}_2$ . Cautious heating of Ag opianate affords opianic anhydride (I) and products among which hemipinic anhydride (II) is identified. Treatment of (I) at a higher temp. with excess of  $\text{Ag}_2\text{O}$  yields about 30% of (II) and 20% of veratraldehyde. About 21% of (I) remains unchanged and 5% of opianic acid is isolated. Similarly, Ag bromopianate yields about 16% of bromo-opianic anhydride, about 25% of bromoveratraldehyde, 0.2% of bromohemipinic anhydride, and 20% of bromohemipinic acid (probably a secondary product formed from traces of  $\text{H}_2\text{O}$  in the Ag salt and the anhydride); bromoveratric acid does not appear to be formed. Bromohemipinimide has m.p. 236—237°.

H. W.

**Choleic acid [complexes].** K. YAMASAKI (J. Biochem. Japan, 1935, 22, 243—249).—The mixed m.p. method (A., 1929, 925) indicates the formation of a 4:1 deoxycholic acid (I)- $\beta$ -carotene complex, m.p. 167°. Treatment of the unsaponifiable fraction of cod-liver oil with EtOH-(I) yields complexes of (I) with high alcohols (mainly selachyl). The fraction, m.p. 185°, converted into the xylene derivative and hydrogenated, affords batyl alcohol (II). M.-p. curves indicate a (I)-(II) (8:1) complex, m.p. 186.5°; such a complex, m.p. 186—187°,  $[\alpha]_D^{25} + 47.37^\circ$  in EtOH, crystallises from (I)+(II) in aq. EtOH.

F. O. H.

**Toad bile. III. Trihydroxyisosterocholenic acid,  $\text{C}_{28}\text{H}_{46}\text{O}_5$ , from winter bile. IV. Constitution of trihydroxybufosterocholenic acid.** T. SHIMIZU and T. KAZUNO (Z. physiol. Chem., 1936, 239, 67—73, 74—75; cf. A., 1934, 1219).—III. Exhaustive extraction of the bile with  $\text{Et}_2\text{O}$ , directly or after saturation with  $\text{CO}_2$ , and further acidification

with AcOH or mineral acid gives trihydroxybusterocholenic acid (I), which is removed as the cryst. Me ester; fractionation of the mother-liquors with 0.1*N*-NaOH affords trihydroxyisosterocholenic acid (II),  $C_{28}H_{46}O_5$ , m.p. 227°,  $[\alpha]_D^{20} +46.95^\circ$  in MeOH, which contains three *sec*.-OH and one double linking, adds Br, and decolorises  $KMnO_4$ . (II) gives a Me ester, m.p. 220°, and is oxidised by  $CrO_3$  in AcOH to triketoisosterocholenic acid (III),  $C_{28}H_{40}O_5$  (Me ester, m.p. 184–186°, and its trioxime, decomp. 231°). Reduction of (III) with Zn–Hg in AcOH–HCl gives isosterocholenic acid,  $C_{28}H_{46}O_5$ , m.p. 186.5–187° (Me ester, m.p. 117°), which adds Br, decolorises  $KMnO_4$ , does not give the Liebermann reaction, and is hydrogenated (PtO<sub>2</sub> in EtOH) to isosterocholenic acid, m.p. 149–149.5° (Na and K salts; Me ester, m.p. 90–90.5°). Reduction (PtO<sub>2</sub> in AcOH) of (II) affords trihydroxyisosterocholenic acid, m.p. 200° after marked softening at 133°,  $[\alpha]_D +38.96^\circ$  in MeOH (Me ester, m.p. 162°), which is oxidised by  $CrO_3$  in AcOH to triketoisosterocholenic acid, m.p. 234° (Me ester, m.p. 223–224°), also formed by hydrogenation (Pd-black in EtOH) of (III). Bromination of (II) in AcOH yields a Br-lactone,  $C_{28}H_{45}O_5Br$ , m.p. 202°, insol. in  $NH_3$ ; (II) therefore appears to contain the double linking in the side-chain and in the  $\delta$ -position to  $CO_2H$ . (II) does not give the Hammarsten reaction so that the three OH are not in the same position as in (I) or cholic acid. (I) and (II) can be readily isolated from summer bile, which contains much < winter bile.

IV. Ozonisation of Me trihydroxyisosterocholenate in cold AcOH or oxidation of it with  $CrO_3$  in warm solution gives products which do not depress the m.p. of  $\alpha$ -bisonorcholenic acid and its Me ester. The double linking of (I) is therefore in the  $\delta$ -position to the  $CO_2H$  of the side-chain.

H. W.

**Lichen substances. LXIII. Components of *Baomyces* varieties.** Y. ASAHINA, Y. TANASE, and I. YOSIOKA. **LXIV. Constitution of thamnolic acid.** IV. Y. ASAHINA and M. HIRATA. **LXV. Ramalinolic acid, a new depside.** Y. ASAHINA and T. KUSAKA (Ber., 1936, 69, [B], 125–127, 330–333, 450–455).—LXIII. Extraction of *B. placophyllus*, Ach., with Et<sub>2</sub>O followed by  $COMe_2$  affords stietic acid, m.p. 272° (decomp.) after softening at 230°. Similar treatment of *B. rosens*, Pers., yields baomycesic acid, (I) decomp. 222° [anil, m.p. 211° (decomp.)] (cf. Koller, *et al.*, A., 1935, 1432). Me baomycesate, m.p. 207°, is reduced (Pd–C in AcOH) to Me barbatate; since it is also formed by the partial methylation of atranorin, (I) is 4-3'-hydroxy-4'-aldehydo-5'-methoxy-*o*-toluoyl-2-hydroxy-3 : 6-dimethylbenzoic acid.

LXIV (cf. A., 1929, 818; 1932, 275). Examination of technical thamnolic acid (II), obtained by extraction of *Cladonia polydactyla* with  $COMe_2$ , discloses the presence of decarboxylthamnolic acid (III), m.p. 215° (decomp.) (anil; *p*-nitrophenylhydrazine, m.p. 219°), also obtained when (II) is heated in  $COMe_2$  at 120–130. (III) and  $CH_2N_2$  in  $COMe_2$  at 0° give the Me ester, m.p. 163°, whereas treatment of (III) with MeI and  $Ag_2CO_3$  in Et<sub>2</sub>O gives the Me ester  $Me_2$  ether, m.p. 183°. Exhaustive treatment of (III) with  $Ag_2O$  and MeI in boiling Et<sub>2</sub>O yields the Me ester  $Me_3$  ether, m.p.

154° transformed by boiling 95%  $HCO_2H$  into Me *H* orcinoldicarboxylate  $Me_2$  ether, m.p. 124° (converted at 200° into Me *p*-orsellinate  $Me_2$  ether, m.p. 84°), and thamnol  $Me_2$  ether, m.p. 104° (semicarbazone, m.p. 216°), which dissolves in KOH to a yellow solution, does not give a colour with  $FeCl_3$ , and is unaffected by  $H_2O_2$  in alkaline solution. (II) is therefore 6-4'-carboxy-3'-hydroxy-5'-methoxy-*o*-toluoyl-4-aldehydo-3 : 5-dihydroxy-*o*-toluic acid.

LXV. Exhaustive extraction of the thalli of *Ramalina farinacea*, Ach., var. *nervulosa*, Müll. Arg., with Et<sub>2</sub>O affords sekikaic acid, the mother-liquors of which contain ramalinolic acid (IV),  $C_{23}H_{28}O_8$ , m.p. 163–164°, which gives an intense blood-red colour with alkali in EtOH, a violet-red colour with  $FeCl_3$ , but no colour with  $CaOCl_2$ . It is hydrolysed by alkali to divaricic acid and an acid,  $C_{12}H_{16}O_5$ , m.p. 163°. Prolonged treatment of (IV) with  $CH_2N_2$  in Et<sub>2</sub>O yields the corresponding Me ester  $Me_3$  ether, m.p. 75°, hydrolysed by KOH–EtOH to divaricic acid Me ether, m.p. 63.5°, and Me amylpyrogallol-carboxylate  $Me_2$  ether (V), m.p. 72–73°. Et 3 : 4 : 5-trimethoxybenzoylacetate is converted by Na and Pr<sup>o</sup>I in EtOH into Et  $\alpha$ -3 : 4 : 5-trimethoxybenzoyl-*n*-valerate, b.p. 214–216° (trimethoxyphenylpropyl-pyrazolone, m.p. 223–224°), hydrolysed by 10% KOH–EtOH to 3 : 4 : 5-trimethoxyvalerophenone (VI), b.p. 190–192°/6 mm. (semicarbazone, m.p. 145–146°). Treatment of (VI) with conc.  $H_2SO_4$  at 38° leads to 4-hydroxy-3 : 5-dimethoxyvalerophenone, m.p. 89–90° (oxidised by  $K_2Cr_2O_7$  and 10%  $H_2SO_4$  to 2 : 6-dimethoxy-*p*-benzoquinone), which is reduced (Clemmensen) to 4-hydroxy-3 : 5-dimethoxy-1-*n*-amylbenzene (VII), b.p. 175°/7 mm. (Bz derivative, m.p. 89°). (VII) is converted by HCN–HCl– $AlCl_3$  into 3-hydroxy-2 : 4-dimethoxy-6-*n*-amylbenzaldehyde, m.p. 52°, which is treated with  $ClCO_2Et$  in  $C_5H_5N$  at –15° and then oxidised by  $KMnO_4$  in  $COMe_2$  whereby 3-carbethoxy-2 : 4-dimethoxy-6-*n*-amylbenzoic acid, m.p. 110–111°, is produced, transformed by  $CH_2N_2$  and subsequent hydrolysis into (V). (IV) is therefore 5-2'-hydroxy-4'-methoxy-6'-propylbenzoyl-4 : 6-dihydroxy-2-amylbenzoic acid.

H. W.

**Acids contained in the wood of *Libocedrus formosna*, Florin.**—See this vol., 395.

**Interaction of hydrogen sulphite derivatives of aromatic aldehydes with potassium cyanide.** S. SCHUSTER (J. Pharm. Chim., 1936, [viii], 23, 142–145).—The  $Na_2SO_3$  compound of PhCHO with KCN gives OH·CHPh·CN and a 12% yield of *N*-benzylidenemandelamide [*Ac* derivative, m.p. 121° (block)], converted by HCl in Et<sub>2</sub>O into a *Cl*-derivative.  $C_{15}H_{12}ONCl$ , m.p. 164°, converted by alkalis into 2 : 4-diphenyloxazole. Similarly the  $Na_2SO_3$  derivative of *p*-OMe· $C_6H_4$ ·CHO gives a substance,  $C_{25}H_{24}O_5N_2$ , m.p. 154° (block), and resinous products.

J. W. B.

**Action of acid chlorides on Schiff's bases. Additive products of these bases.** I. TANASESCU and A. SILBERG (Bull. Soc. chim., 1936, [v], 3, 224–239).—Schiff's bases, CHR·NPh, and acid chlorides, R'·COCl, in neutral solvents ppt. hydrochlorides, CHR·NPh}Cl (I) and  $NH_2Ph$ ·HCl in varying proportions, whilst the solution contains R·CHO,

$R'-CO_2H$ , and  $R'-CO-NHPh$ . Reaction does not occur in complete absence of  $H_2O$  and depends on hydrolysis first of  $R'-COCl$  and then of (I) (demonstrated on the isolated compound). Experiments are quoted in which  $R=Ph$ , *o*-, *m*-, and *p*- $NO_2-C_6H_4$ ,  $R'=Me$ ,  $Ph$ , *m*- $NO_2-C_6H_4$ . Addition to Schiff's bases occurs on the N; reaction with Br proceeds thus:  $CHR:NPhBr_2 \rightarrow HBr + [CHR:NPhBr]OH \rightarrow$

$OH \cdot CHR:NPhBr \rightarrow R \cdot CHO + H_2O + NHPhBr \rightarrow$   
 $NH_2 \cdot C_6H_4Br$  (II), followed possibly by bromination of  $R \cdot CHO$  or (II). *Hydrochlorides of benzyldene*, m.p. 176°, *m*-, m.p. 181° after previous sintering, *o*-, m.p. 156°, and *p*-nitrobenzyldene-aniline, m.p. 190—193°, are described. R. S. C.

**Hydrogen cyanide. VI. Mechanism of Gattermann's hydrogen cyanide aldehyde synthesis.** L. E. HINKEL, E. E. AYLING, and J. H. BEYNON (J.C.S., 1936, 184—185).—Resorcinol (I), HCN, and HCl at room temp. give resorcyraldehyde (72%), and at 0°, the solid, m.p. 166—170° (decomp.), first formed, corresponds with a mixture of aldimine hydrochloride and dichloromethylformamide hydrochloride. Iminoformylcarbylamine, HCl, and (I) yield *resorcyldimethylformamide hydrochloride*, m.p. 135° (decomp.), decomposed by  $H_2O-HCl$  to the aldehyde, and also obtained from (I) and chloromethyleneformamide. This confirms the primary reaction as tendency to form iminoformyl chloride before derivatives of the dimeride. F. R. S.

**Phenylglyoxal.** H. L. RILEY and A. R. GRAY (Org. Syntheses, 1935, 15, 67—69).— $COPhMe$  is oxidised with  $SeO_2$ . CH. ABS. (r)

**Benzoin reaction. V. Effect of inhibitors on the reaction.** B. F. FERREIRA and T. S. WHEELER (Proc. Indian Acad. Sci., 1935, 2, A, 604—614).—The rate of reaction of  $PhCHO$  and solid KCN in presence of S (cf. A., 1935, 1329) and the inhibition caused by benzoquinone, I,  $PhCNS$ , and  $CS_2$  are studied. Inhibition is due to adsorption of inhibitors on the KCN.  $PhCHO$  (containing inhibitors) may be purified by keeping with a small quantity of KCN, under  $N_2$ , and filtering, after which it gives improved yields of benzoin; 0.1 g. of KCN purifies 50 g. of  $PhCHO$ . E. W. W.

**Kinetics of gaseous Diels-Alder reactions.**—See this vol., 297.

**Kinetics of the benzoin reaction in presence of organic solvents.**—See this vol., 297.

**Structure and absorption spectra of benzocycloalkanoneoximes.** (MME.) P. RAMART-LUCAS and J. HOCH (Compt. rend., 1935, 201, 1387—1390).—Absorption spectra indicate that the oximes of indan-1-one, 2:2-dimethylindan-1-one, and  $\alpha$ -tetralone have the  $C=N \cdot OH$  structure, but that of 2:2-dimethyl-1-tetralone has the *isooxime* structure,  $C \begin{smallmatrix} \text{NH} \\ \diagup \end{smallmatrix} \diagdown O$ . Benzocycloheptan-1-oneoxime exists mainly in the  $N \cdot OH$ , but its 2:2- $Me_2$  derivative mainly in the *isooxime*, form. The structure of the oxime is thus dependent on the influence of valency angles on the elimination of  $H_2O$  from  $OH \cdot CRR' \cdot NH \cdot OH$ , which is the primary product from a ketone and  $NH_2OH$ . R. S. C.

**$\alpha$ -Tetralone ( $\alpha$ -ketotetrahydronaphthalene).** E. L. MARTIN and L. F. FIESER (Org. Syntheses, 1935, 15, 77—79).— $Ph \cdot [CH_2]_3 \cdot COCl$  is treated with  $AlCl_3$  in  $CS_2$ . CH. ABS. (r)

**Ternary catalyst  $Cu-ZnO-Cr_2O_3$  as hydrogenation catalyst.**—See this vol., 298.

**Molecular conversion of ketones into [different] ketones by the action of zinc chloride at high temperatures.** M. A. FAVORSKI [with (MLLE.) T. E. ZALESSKAJA, D. I. ROSANOV, and G. V. TSHELINCEV] (Bull. Soc. chim., 1936, [v], 3, 239—248).—Ketones,  $CR_3 \cdot COPh$  ( $R$  is aliphatic), with  $ZnCl_2$  at about 320° give  $CPhR_2 \cdot COR$ , but ketones with no *tert*-C decompose. Isomerisation may proceed by way of an oxide or by direct interchange of position between O and two radicals.  $COPhEt$  with  $ZnCl_2$  at 320—330° gives  $CO$ ,  $CO_2$ ,  $BzOH$ ,  $EtCO_2H$ ,  $H_2O$ ,  $C_2H_4$ ,  $C_6H_6$ ,  $PhPr$ , and  $CHPh \cdot CHMe$ ; pyrolytic decomp., hydrolytic fission of the ketone, reduction to the hydrocarbon and alcohol, and dehydration of the alcohol must occur simultaneously. *cycloHexyl Ph ketone* (*semicarbazone*, m.p. 167°), obtained from *cyclohexylphenylcarbinol*, with  $ZnCl_2$  at 350—450° gives  $CO$  and *phenylcyclohexane*, b.p. 247—249°.  $MgBu^iBr$  and  $PhCHO$  give *phenyl-tert-butylcarbinol*, m.p. 44—45°, oxidised to *Ph Bu^i ketone*, b.p. 109°/22 mm. (*semicarbazone*, m.p. 159°), which with  $ZnCl_2$  at 320—330° gives  $\alpha$ -phenylisopropyl *Me ketone*, b.p. 97—98°/11 mm. (*semicarbazone*, m.p. 190—191°; oxidised by  $NaOBr$  to  $CPhMe_2 \cdot CO_2H$ ).  $CMe_2Et \cdot MgCl$  and  $PhCHO$  give *phenyl-tert-amylcarbinol*, b.p. 112—114°/8.5 mm., m.p. 22°, oxidised by  $CrO_3$  to *Ph tert-amyl ketone*, b.p. 112°/10 mm. (*semicarbazone*, m.p. 127—128°), which with  $ZnCl_2$  at 320—330° gives  $\beta$ -phenyl-sec-butyl *Me ketone*, b.p. 114—116°/13 mm. (*semicarbazone*, m.p. 177—178°; with  $NaOBr$  gives  $\alpha$ -phenyl- $\alpha$ -methylbutyric acid, m.p. 64°). R. S. C.

**Reactions of benzoyl chloride [fluoride].** C. L. TSENG and S. W. MAI (J. Chinese Chem. Soc., 1936, 4, 22—26).— $BzF$  (prep. from  $BzCl$  and  $KHF_2$  in a Cu retort in 67—80% yield) is unstable and attacks glass if slightly impure; with  $(NH_4)_2CO_3$  it gives  $NH_2Bz$  and with  $C_6H_6$  and freshly prepared  $AlCl_3$  in  $CS_2$  gives 64% of  $COPh_2$  more readily than does  $BzCl$ . R. S. C.

**5:5-Dimethyl-1:3-hexanedione (5:5-dimethyldihydroresorcinol).** R. L. SHRINER and H. R. TODD (Org. Syntheses, 1935, 15, 14—16).—A modified prep. from  $CMe_2 \cdot CHAc$  and  $CH_2(CO_2Et)_2$  is described. CH. ABS. (r)

**Action of selenium dioxide on some cyclanones.** M. GODCHOT and (MLLE.) G. CAUQUIL (Compt. rend., 1936, 202, 326—328; cf. A., 1932, 833).—*cyclo-Hex*-, *-hept*-, and *-oct*-anone with  $SeO_2$  in  $EtOH$  at 80° give 1:2-diones. The following are prepared similarly: 4-methyleyclohexane-1:2-dione, m.p. 37—38° [*dioxime*, m.p. 195—196° ( $Bz_2$  derivative, m.p. 218°); *diphenylhydrazone*, m.p. 148°; affords  $\beta$ -methyladipic acid with  $H_2O_2$ ]; 4-ethoxy-5-keto-2-methyl- $\Delta^6$ -cyclohexene, b.p. 118°/20 mm., is formed by a side reaction], and *cycloheptane-1:2-dione*, b.p. 107—109°/17 mm. [*diphenylhydrazone*, m.p. 135°; *dioxime*, m.p. 181—

182°; oxidised to pimelic acid). 2-Methylcyclohexanone affords 2:3-diketo-1-methyl- $\Delta^6$ -cyclohexene, b.p. 92—93°/16 mm. (diphenylhydrazone, m.p. 150°), which probably results from the dehydration of 3-hydroxy-3-methylcyclohexane-1:2-dione. cyclo-Octanone similarly affords 8-ethoxycyclooctane-1:2-dione, b.p. 133—135°/15 mm. J. L. D.

**Methyl  $\beta$ -m-nitrophenyl- $\beta$ -hydroxyethyl and m-nitrostyryl ketones.** W. KRASZEWSKI and B. WEICÓWNA (Rocz. Chem., 1935, 15, 506—509).—m-NO<sub>2</sub>·C<sub>6</sub>H<sub>4</sub>·CHO and COMe<sub>2</sub> in presence of 1% NaOH at room temp. yield a trimeride of m-nitrostyryl Me ketone, m.p. 232° (phenylhydrazone, m.p. 183°), also obtained, together with  $\beta$ -m-nitrophenyl- $\beta$ -hydroxyethyl Me ketone (I), m.p. 62° (benzoate, m.p. 107°; semicarbazone, m.p. 162°), which is the sole product at  $\pm$  5°. (I) yields m-nitrostyryl Me ketone, m.p. 90° (semicarbazone, m.p. 223°; Br-derivative, m.p. 112°), with Ac<sub>2</sub>O (1 hr. at the b.p.). R. T.

**Chrysene.** I. K. FUNKE and E. MÜLLER. II. K. FUNKE, E. MÜLLER, and L. VADASZ (J. pr. Chem., 1936, [ii], 144, 242—250, 265—272).—I. Chrysene (I), BzCl, and AlCl<sub>3</sub> in CS<sub>2</sub> give (probably) 2-benzoylchrysene (II), m.p. 191° [7:8-quinone, m.p. 249—250°, formed on oxidation (Na<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>, AcOH)], which is reduced (Clemmensen) to 2-benzylchrysene, m.p. 200°, and converted by AlCl<sub>3</sub> at 130° into (probably) a naphthobenzanthrone (not characterised). (I), AcCl, and AlCl<sub>3</sub> in CS<sub>2</sub> afford 1-, m.p. 254°, and 2- (III), m.p. 144°, -acetylchrysene, reduced (Clemmensen) to 1-, m.p. 236°, and 2-ethylchrysene, m.p. 126° (Br-derivative, m.p. 122°), respectively. (III) is oxidised (NaOCl) to chrysene-2-carboxylic acid, m.p. 308° (lit. 303°) [chloride (IV), m.p. 167°; Et ester, m.p. 124° (indef.)], also prepared by Liebermann and Zsuffa's method (A., 1911, i, 202). (IV), C<sub>6</sub>H<sub>6</sub>, and AlCl<sub>3</sub> give (II).

II. BzCl (excess), (I), and AlCl<sub>3</sub> afford two dibenzoylchrysenes, A, m.p. 208° [also obtained from (II), BzCl, and AlCl<sub>3</sub> in CS<sub>2</sub>], and B, m.p. 252°. Dibromochrysene, m.p. 270° [from (I) and Br in CCl<sub>4</sub>], and Cu<sub>2</sub>(CN)<sub>2</sub> in quinoline give dicyanochrysene, m.p. >360°, hydrolysed (powdered KOH in MeOH at 200°) to chrysenedicarboxylic acid, m.p. >360° [chloride (V), m.p. >360°, best prepared using BzCl; Et ester, m.p. 169°; amide; anilide, m.p. >360°], which could not be converted into an anhydride. Bromo-2-benzoylchrysene, m.p. 176° [from (II) and Br in AcOH], is similarly converted into the nitrile, m.p. 207°, of 2-benzoylchrysenedicarboxylic acid, m.p. 286° (previous sintering), the chloride of which could not be prepared. (V), C<sub>6</sub>H<sub>6</sub>, and AlCl<sub>3</sub> give dibenzoylchrysene-C, m.p. 232°, reduced (Clemmensen) to dibenzylchrysene-C, m.p. 254°. (V) and N<sub>2</sub>H<sub>4</sub>·H<sub>2</sub>O afford a compound, C<sub>40</sub>H<sub>30</sub>O<sub>4</sub>N<sub>6</sub>, m.p. >360°. The colours of most of the above compounds in conc. H<sub>2</sub>SO<sub>4</sub> are given. H. B.

**Synthesis of substances related to the sterols.** VIII. A ketomethoxymethylhexahydrophenanthrene. R. ROBINSON and J. WALKER (J.C.S., 1936, 192—195).—The Na compound of Me  $\gamma$ -acetyl- $\alpha$ -methylbutyrate, b.p. 110—112°/24 mm., and  $\gamma$ -methoxyphenylbutyryl chloride yield Me  $\gamma$ -methoxyphenylbutyrate and Me 5-keto-8-m-methoxy-

phenyloctane-2-carboxylate (I), b.p. 210°/1 mm. (I) and NaOEt give a dihydroresorcinol derivative, which with P<sub>2</sub>O<sub>5</sub> affords 1-keto-7-methoxy-2-methyl-1:2:3:4:9:10-hexahydrophenanthrene (II), m.p. 67—68° (2:4-dinitrophenylhydrazone, m.p. 221°), mixed with some 4-Me isomeride. (I) and H<sub>2</sub>SO<sub>4</sub> at -15° give Me  $\gamma$ -6-methoxy-3:4-dihydro-1-naphthyl- $\alpha$ -methylbutyrate, b.p. 181—183°/0.5 mm., the corresponding chloride being cyclised by Darzens' reaction. The ketone obtained is identical with (II); this method proves the constitution but the first method is to be preferred for prep. F. R. S.

**Sexual hormones and related substances.**

VII. Carboxylic derivatives of the follicle hormone. VIII. Catalytic hydrogenation of the follicle hormone and its acyl derivatives. W. DIRSCHERL (Z. physiol. Chem., 1936, 239, 49—52, 53—66).—VII. Follicle hormone (I) is largely unaffected by treatment with an equiv. amount of (C<sub>5</sub>H<sub>5</sub>N)<sub>2</sub>COCl<sub>2</sub> in C<sub>6</sub>H<sub>6</sub> but is quantitatively transformed by an excess of the reagent at 70—75° into the chloroformate (II), m.p. 101—102° (corr.). (II) is converted by EtOH at 80° into the corresponding Et carbonate, m.p. 115° (corr.), [ $\alpha$ ]<sub>D</sub><sup>25</sup> +114° in dioxan, also obtained from (I) and ClCO<sub>2</sub>Et in C<sub>6</sub>H<sub>6</sub>-C<sub>5</sub>H<sub>5</sub>N at 70—75°. (II) is transformed by MeOH into the Me carbonate, m.p. 127° (corr.), and by NHET<sub>2</sub> in C<sub>6</sub>H<sub>6</sub> into the diethylcarbamate, m.p. 194—195° (corr.). (I) and COCl<sub>2</sub> in alkaline solution afford the normal carbonate, m.p. 247° (corr.), and (II). (II) is about 10 times as active physiologically as (I), excelling all other hormone esters in this respect.

VIII. Hydrogenation of 17-keto-3-hydroxy- $\Delta^{1:3:5}$ -cestratriene (III) (PtO<sub>2</sub>-EtOH; room temp.) affords the dehydrohormone (IV), m.p. 174—175°, [ $\alpha$ ]<sub>D</sub><sup>25</sup> +82° in dioxan, which is 5—10 times as active as (III). Similar results are obtained at 70°, in EtOH-H<sub>2</sub>O at room or elevated temp. or when PtO<sub>2</sub> is reduced to Pt before hydrogenation, whereas hydrogenation does not occur with Pt-black under these conditions. Under like circumstances (IV) is also derived from the Bz, Ac, ClCO<sub>2</sub>, or EtCO<sub>2</sub>-derivative of (III). Hydrogenation (PtO<sub>2</sub>) of (I) in EtOH-HCl gives a small amount of (IV) and unchanged (III) but essentially affects the nucleus; the isolation of two octahydrohormones, m.p. 210—211° (corr.), [ $\alpha$ ]<sub>D</sub><sup>25</sup> +7.2° in EtOH (V), and m.p. 154—155°, [ $\alpha$ ]<sub>D</sub><sup>25</sup> +31.4° in EtOH, respectively, and of two deoxohexahydrohormones, m.p. 104—105° after softening at 100°, [ $\alpha$ ]<sub>D</sub><sup>25</sup> +1.8° in EtOH, and m.p. 96—100°, [ $\alpha$ ]<sub>D</sub><sup>25</sup> +12.3° in EtOH, respectively, is described. Hydrogenation of (III) in AcOH affords (V) and lower-melting isomerides of it, deoxohexahydrohormones, and, apparently, a hexahydrohormone which yields a semicarbazone, m.p. 255°, [ $\alpha$ ]<sub>D</sub><sup>25</sup> +77.2° in CHCl<sub>3</sub>-EtOH (3:1). In 60% or 80% AcOH hydrogenation proceeds similarly but yields the products in different ratio. In 80% AcOH at 40° the main product is a mixture of ketones from which a hexahydrohormone-2:4-dinitrophenylhydrazone, m.p. 105—110°, and a semicarbazone, m.p. 255°, [ $\alpha$ ]<sub>D</sub><sup>25</sup> +46° in EtOH, are derived. H. W.

**Sexual hormones.** XI. Partial hydrolysis of cis-trans-androstane-3:17-diol and its partial esterification. Specificity of sexual hormone

action. L. RUZICKA and M. W. GOLDBERG (Helv. Chim. Acta, 1936, 19, 99—106).—Partial hydrolyses of *cis-trans*-androstan-3 : 17-diol diacetate with KOH—EtOH gives *cis-trans*-androstan-17-ol 3-acetate, m.p. 183—184°. Partial esterification of *cis-trans*-androstan-3 : 17-diol with 90% AcOH or Ac<sub>2</sub>O in C<sub>5</sub>H<sub>5</sub>N gives good yields of *cis-trans*-androstan-3-ol 17-acetate, m.p. 191—192° (corr.), oxidised by CrO<sub>3</sub> in AcOH to *androstan-3-one* 17-acetate, m.p. 158° (corr.), whence *trans-androstan-3-one*-17-ol (I), m.p. 180—181° (corr.), which is physiologically somewhat less active than testosterone (II). Comparison of the action of derivatives of (I) shows that 17-methyltestosterone, not observed naturally, is physiologically more active than (II) and that chemical structure has little specificity in the male hormone action. *cis*-Androstanediol 3-acetate is transformed by BzCl in C<sub>5</sub>H<sub>5</sub>N into *cis-trans-androstanediol-3-acetate* 17-benzoate, m.p. 198—199° (decomp.), which when partly hydrolysed by KOH—MeOH affords *cis-androstanediol* 17-benzoate, m.p. 203—204° (corr.) (the use of a difficultly hydrolysable acid residue at C-17 is particularly useful, but traces of the 3-acetate are observed), oxidised to *androstan-3-ol* 17-benzoate, m.p. 200—201° (corr.), hydrolysed to (I). H. W.

**17-Ethylandrostenediol and 17-ethyltestosterone.** A. BUTENANDT, H. COBLER, and J. SCHMIDT (Ber., 1936, 69, [B], 448—450).—Dehydroandrosterone is converted by MgEtI in Et<sub>2</sub>O into Δ<sup>5,6</sup>-17-ethylandrosten-3 : 17-diol, m.p. 198° (also +1H<sub>2</sub>O) (cf. Ruzicka *et al.*, this vol., 76), which is treated successively with Br and CrO<sub>3</sub> in AcOH and debrominated by Zn dust in MeOH thereby giving 17-ethyltestosterone, m.p. 149° after softening at 144°, [α]<sub>D</sub><sup>20</sup> −35.3° in abs. EtOH [semicarbazone, m.p. 210° (decomp.)]. H. W.

**Androsterone and related sterols.** R. E. MARKER, F. C. WHITMORE, O. KAMM, T. S. OAKWOOD, and J. M. BLATTERMAN (J. Amer. Chem. Soc., 1936, 58, 338—340).—Oxidation (CrO<sub>3</sub> in dil. AcOH at 70°) of 3-chloro-5 : 6-dibromocholestan-3-ol (from cholesteryl chloride and Br in Et<sub>2</sub>O—AcOH) and reduction (Zn dust, AcOH) of the product formed gives 3-chloro-Δ<sup>5</sup>-dehydrocholan-3-ol and 3-chloro-Δ<sup>5</sup>-dehydroandrosterone (I), m.p. 156—157° (Butenandt and Dannenbaum, A., 1935, 413). Reduction (H<sub>2</sub>, PtO<sub>2</sub>, Et<sub>2</sub>O) of (I) affords α-3-chloroandrosterone (II), m.p. 165—168°, converted by KOAc in valeric acid, subsequent hydrolysis (aq. EtOH—NaOH), and purification through the H succinate into androsterone, m.p. 178°. (II) is also obtained from isoandrosterone (III) (Ruzicka *et al.*, A., 1934, 1221) and SOCl<sub>2</sub>. Hydrolysis of (I) gives Δ<sup>5</sup>-dehydroisoandrosterone which is reduced to (III). Reduction (H<sub>2</sub>, PtO<sub>2</sub>, Et<sub>2</sub>O—AcOH) of cholesteryl bromide affords *cholesteryl bromide*, m.p. 115° [also prepared from epicholesterol (IV) and PBr<sub>3</sub> in C<sub>6</sub>H<sub>6</sub>], which is hydrolysed [as for (II)] to (IV). H. B.

**Cortin, the hormone of the adrenal cortex.** I. T. REICHSTEIN (Helv. Chim. Acta, 1936, 19, 29—63).—There is no discrepancy between the Swingle—Piffner assay on dogs and the Everse—de Fremery test on rats if it is assumed that the same material is concerned in each method; per kg.

body-wt., rats require about 500 times as much hormone as dogs. Distribution of cortin extracts between pentane and 20% MeOH permits the isolation of all the physiologically active material in sufficient purity to allow further concn. to be effected without marked loss. The total hormone can be extracted from the concentrates by suitable ketonic reagents (NH<sub>2</sub>·CO·NH·NH<sub>2</sub> or Girard's reagent). The biologically active components from 1000 kg. of cortex can thus be reduced simply to about 5.4 g. without appreciable loss of activity. The preps. so obtained are essentially mixtures of OH-ketones and diketones. They are free from N, S, P, and halogen and contain about 3 rat units per mg. The following inter-related and closely allied to the active components, have been obtained partly from the active concentrates and partly from the inactive by-products; all are biologically inactive with the doses used. *Substance A*, C<sub>21</sub>H<sub>36</sub>O<sub>5</sub>±2H, m.p. 222—224° (decomp.) after becoming opaque at about 160°, [α]<sub>D</sub><sup>20</sup> +16° (±1°) in abs. EtOH; it contains 4 or 5 OH, gives a cryst. ppt. with digitonin in 50% MeOH, is not hydrogenated at 100—140°/100 atm. in presence of Ni—SiO<sub>2</sub>, yields a *tetra-* or *penta-acetate*, m.p. 150—151° (corr.), and a *monoisopropylidene* derivative, m.p. 209—210° (corr.), and yields CH<sub>2</sub>O when oxidised by Pb(OAc)<sub>4</sub> in AcOH. *Substance B*, C<sub>16</sub>H<sub>28</sub>O<sub>5</sub> or, more probably, C<sub>12</sub>H<sub>20</sub>O<sub>4</sub>, m.p. 253—255° in sealed capillary, is possibly a degradation product. *Substance C*, C<sub>21</sub>H<sub>34</sub>O<sub>5</sub>, m.p. 253—256° (corr.; decomp.), [α]<sub>D</sub><sup>20</sup> +69.8°±2.5° in abs. EtOH [monosemicarbazone, m.p. 265—267° (corr.; decomp.)]. *Substance D*, C<sub>21</sub>H<sub>36</sub>O<sub>5</sub> or C<sub>21</sub>H<sub>34</sub>O<sub>5</sub>, m.p. about 230—238° (corr.; decomp.) according to the rate of heating, [α]<sub>D</sub><sup>20</sup> +66°±1.5° in abs. EtOH [monosemicarbazone, m.p. 327—329° (corr.; decomp.)]. *Substance F*, probably C<sub>18</sub>H<sub>24</sub>O<sub>3</sub>, m.p. 220—223° (corr.), [α]<sub>D</sub><sup>20</sup> +262° in abs. EtOH [disemicarbazone, gradual decomp. about 270°]. An *acid*, m.p. 223—226°, [α]<sub>D</sub><sup>20</sup> +166°±20° (determined as Na salt in H<sub>2</sub>O), and *substance E*, m.p. (indef.) 126—129° [semicarbazone, C<sub>25</sub>H<sub>37</sub>O<sub>5</sub>N<sub>3</sub>, m.p. (amorphous), 208—210°, m.p. (cryst.), 280—285° (corr.; decomp.)]. Hydrolysis of the fat insol. in pentane gives a substance, C<sub>4</sub>H<sub>10</sub>O<sub>3</sub>S, m.p. 113—114.5° (corr.), probably an aliphatic trihydroxy-sulphide or dihydroxysulphoxide, which is stable towards alkaline Ag solution but immediately decolorises KMnO<sub>4</sub> at 0°, glyceryl palmitate, and palmitic acid. H. W.

**1 : 2 : 3-Triketotetramethylcyclopentane :** a blue triketone. C. W. SHOPPEE (J.C.S., 1936, 269—274).—Francis and Willson (J.C.S., 1913, 103, 2238) state that 1 : 1-dibromo-2 : 2 : 3 : 3-tetramethylcyclopentanediol (I) and NaOAc give a colourless Br-free compound, m.p. 100°, regarded as a diacetate, and converted by KOH into a substance, m.p. 68°. (I) with NaOAc—MeOH yields 1 : 2 : 3-triketotetramethylcyclopentane hydrate (II), m.p. 95°, which forms a hydrate monosemicarbazone, m.p. 153° (decomp.), 2 : 4-dinitrophenylhydrazine, m.p. 219—220°, 2 : 4-dinitrophenyllosazone (? 1 : 3-bis-2' : 4'-dinitrophenylhydrazine), m.p. 268—270° (decomp.), and a quinoxaline, m.p. 108°, and a mol. compound of the

ketone (1 mol.) and its hydrate (1 mol.), m.p. 119—120°. (II) and KOH give the hydrate of the lactonic acid of  $\gamma$ -hydroxy- $\alpha\beta$ -tetramethylglutaric acid, m.p. 68°. (II) is dehydrated (80%) in vac. to the anhyd. triketone (III), m.p. 164°, bright blue prisms. (I) and AgOAc-MeOH afford 1:1-dimethoxy-2:2:3:3-tetramethylcyclopentanedione (IV), m.p. 68°, rose-red cubes [2:4-dinitrophenyllosazone, m.p. 266° (decomp.)], oxidised ( $H_2O_2$ ) to the lactone of  $\gamma$ -hydroxy- $\gamma$ -methoxy- $\alpha\beta$ -tetramethylglutaric acid, m.p. 58°, and tetramethylsuccinic acid. (IV) is hydrolysed (HCl) to (III) and 2:2-dimethoxytetramethylcyclopentane-1:3-dione, m.p. 62° (2:4-dinitrophenylhydrazone, m.p. 184°), also obtained from (I) and KOH-MeOH. The absorption spectra of (III) show that the blue colour is due to an absorption band with a max. at 685 m $\mu$  and the red colour of (IV) is due to an unsymmetrical band at 510 m $\mu$ ; the blue colour must be ascribed to the contiguous association of the three CO groups.

F. R. S.

**Chelation. III. Stabilisation of Kekulé forms in *o*-hydroxy-carbonyl compounds.** W. BAKER and (Miss) O. M. LOTHIAN (J.C.S., 1936, 274—281).—4-O-Allylresorpiophenone (I), b.p. 174°/14 mm. (Cu derivative, m.p. 158°), undergoes rearrangement by heating to 3-allylresorpiophenone, m.p. 124° (Me<sub>2</sub> ether, b.p. 180°/18 mm.), reduced to 3-n-propylresorpiophenone, m.p. 109—110°, also obtained from 2-n-propylresorcinol, EtCN, and ZnCl<sub>2</sub>. (I) is methylated (Me<sub>2</sub>SO<sub>4</sub>) to 2-O-methyl-4-O-allylresorpiophenone, m.p. 31°, rearranged on heating to 2-O-methyl-5-allylresorpiophenone, m.p. 132—133° (Me<sub>2</sub> ether, m.p. 67°). 4-O-Allyl- $\beta$ -resorcylaldehyde, b.p. 149—150°/3 mm., obtained from  $\beta$ -resorcylaldehyde and allyl bromide, is rearranged to 3-allyl- $\beta$ -resorcylaldehyde (II), m.p. 129—130°, which is methylated to 2-O-methyl-4-O-allyl- $\beta$ -resorcylaldehyde (III), m.p. 45°, and 2-methoxy-4-allyloxystyryl Me ketone, m.p. 39—40°. (III) is rearranged to 2-O-methyl-5-allyl- $\beta$ -resorcylaldehyde, m.p. 145—146°, methylated to 2:4-dimethoxy-5-allylstyryl Me ketone, m.p. 76—77°: the isomeric 2:4-dimethoxy-3-allylstyryl Me ketone, m.p. 45°, is obtained by methylation of (II). (II) is reduced ( $H_2$ -Pd) to 4-methyl-2-n-propylresorcinol, m.p. 96—97°, also obtained by reduction of 3-n-propyl- $\beta$ -resorcylaldehyde, m.p. 92—93°, prepared from the corresponding phenol.

2-Hydroxy-5-allyloxyacetophenone (IV), m.p. 59—60°, prepared from the (OH)<sub>2</sub>-compound and allyl bromide, is rearranged to 2:5-dihydroxy-6-allylacetophenone, m.p. 105—106°, methylated to the 2:5-(OMe)<sub>2</sub>-compound, b.p. 164—165°/14 mm., which with PhCHO gives 2:5-dimethoxy-6-allylphenyl styryl ketone, m.p. 75°. (IV) is methylated to 2-methoxy-5-allyloxyacetophenone, b.p. 166°/13 mm., rearranged to 5-hydroxy-2-methoxy-6-allylacetophenone, m.p. 104°, and -4-allylacetophenone. 2:4-Dimethoxy-3-allylacetophenone gives a semicarbazone, m.p. 159—160°. These experiments do not afford evidence of a stable Kekulé form in 2:5-dihydroxyacetophenone, but are in harmony with the view that such a stable form exists.

The rearrangement of the following allyl ethers does not take place smoothly: 4-ethylresorcinol diacetate,

b.p. 162°/14 mm., and diallyl ether, b.p. 146°/10 mm., Et 4-O-allyl- $\beta$ -resorcylate, m.p. 42°, and the acid, m.p. 155—156°; 4-nitroresorcinol 1-O-allyl ether, b.p. 157—158°/10 mm., rearranged (26%) to 4-nitro-6(or 2)-allylresorcinol, m.p. 85·5°; nitroquinol diallyl ether, m.p. 22°, and 2-nitroquinol 4-O-allyl ether, m.p. 48°.

F. R. S.

**Reactions of *o*-hydroxybenzylidenediace-phenones. VI. Diacetophenones derived from 3-methoxysalicylaldehyde.** G. H. BEAVEN and D. W. HILL (J.C.S., 1936, 256—258).—3-Methoxysalicylaldehyde, CPhMe, and NaOH give 3-methoxysalicylidenediacephenone (I), m.p. 145—146°, and 3-methoxychalcone; with the appropriate ketone the following are prepared: 3-methoxysalicylidenedi-(*p*-methoxyacetophenone) (II), m.p. 163—164°, and 3:4'-dimethoxychalcone, m.p. 142°; 3-methoxysalicylidenedi-(*p*-methylacetophenone) (III), m.p. 112°, and 3-methoxy-4'-methylchalcone, m.p. 131°. (I) in boiling AcOH for 1 hr. affords 8-methoxy-4-phenacylidene-flavene, m.p. 192° (8-methoxy-4-phenacylflavylum ferrichloride, m.p. 197—198°), and for 10 min. yields 8-methoxy-4-phenacylflavene, m.p. 136—137°, and with HCl-FeCl<sub>3</sub> it forms 8-methoxyflavylum ferrichloride, m.p. 162° (lit., 157°). (II) and AcOH afford 8:4'-dimethoxy-4-(*p*-methoxyphenacylidene)flavene, m.p. 195° (ferrichloride, m.p. 193°). (III) with AcOH gives 8-methoxy-4-(*p*-methylphenacylidene)-4'-methylflavene, m.p. 200° [ferrichloride, m.p. 192° (decomp.)], with Ac<sub>2</sub>O forms 2-acetoxy-3-methoxybenzylidenedi-(*p*-methylacetophenone), m.p. 120°, and with HCl-FeCl<sub>3</sub> affords 8-methoxy-4'-methylflavylum ferrichloride, m.p. 179° (decomp.).

F. R. S.

**4'-Hydroxy-2-*p*-hydroxybenzoylbenzophenone.** F. F. BLICKE and R. A. PATELSKI (J. Amer. Chem. Soc., 1936, 58, 273—276).— $\alpha$ -Di-*p*-chlorophenylphthalide (I), m.p. 157—158° [from *o*-C<sub>6</sub>H<sub>4</sub>(COCl)<sub>2</sub>, PhCl, and AlCl<sub>3</sub>], is reduced (Zn dust, aq. EtOH-NaOH) to 4':4'-dichlorotriphenylmethane-2-carboxylic acid, which with conc. H<sub>2</sub>SO<sub>4</sub> gives 3-chloro-9-*p*-chlorophenyl-10-anthrone (II), m.p. 143—144°. Oxidation (Na<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>, AcOH) of (II) affords 3-chloro-9-hydroxy-9-*p*-chlorophenyl-10-anthrone (III), m.p. 223—224° (Me ether, m.p. 165—166°), which with HCl in C<sub>6</sub>H<sub>6</sub>-AcCl gives 3:9-dichloro-9-*p*-chlorophenyl-10-anthrone, m.p. 121—122°, converted by mol. Ag in C<sub>6</sub>H<sub>6</sub> into the deep red free radical 3-chloro-9-*p*-chlorophenyl-10-anthranyl [peroxide, m.p. 255—265° (decomp.)]. Contrary to Baeyer (A., 1880, 650). (I) could not be obtained from phenolphthalein and PCl<sub>5</sub>; (III) is produced. 4'-Hydroxy-2-*p*-hydroxybenzoylbenzophenone (IV) (A., 1932, 617) [the supposed 3:9-dihydroxy-9-*p*-hydroxyphenyl-10-anthrone of Baeyer (*loc. cit.*) and PCl<sub>5</sub> at 120—125° give 4'-chloro-2-*p*-chlorobenzoylbenzophenone, m.p. 167—168° [the (III) of Baeyer] [bisphenylhydrazone, m.p. 202—203° (decomp.)], reduced (Zn dust, AcOH) to 2:5-di-*p*-chlorophenyl-3:4-benzofuran, m.p. 199—200° [the (II) of Baeyer]. Further reduction affords (probably) the 2:5-dihydrobenzofuran [the 3-chloro-10-hydroxy-9-*p*-chlorophenyl-9:10-dihydroanthracene of Baeyer (*loc. cit.*)]. Further proof of the structure of (IV) is given by the synthesis of its Me<sub>2</sub> ether (V), m.p. 157—159°, from *o*-CN·C<sub>6</sub>H<sub>4</sub>·CO<sub>2</sub>Et (VI) and

*p*-OMe·C<sub>6</sub>H<sub>4</sub>·MgI (VII). (V) is also prepared by oxidation (method: *loc. cit.*) of 2:5-dianisyl-3:4-benzofuran [from (VII) and anisylphthalide]. MgPhBr and (VI) afford *o*-benzoylbenzophenone. H. B.

**Phloracetophenone.** K. C. GULATI, S. R. SETH, and K. VENKATARAMAN (Org. Syntheses, 1935, 15, 70—71).—*s*-C<sub>6</sub>H<sub>3</sub>(OH)<sub>3</sub> is treated with MeCN, ZnCl<sub>2</sub>, and HCl. CH. ABS. (r)

**2:6-Dibromobenzoquinone-4-chloroimide.** W. W. HARTMAN, J. B. DICKY, and J. G. STEMPFLI (Org. Syntheses, 1935, 15, 8—10).—Reduction of 2:6-dibromo-4-nitrophenol with Sn and HCl gives a quant. yield of 2:6-dibromo-4-aminophenol stannichloride, which is oxidised with NaOCl.

CH. ABS. (r)

**Diene reaction between tetramethyl-*o*-benzoquinone and cyclopentadiene.** L. I. SMITH and L. R. HAC (J. Amer. Chem. Soc., 1936, 58, 229—234).—Tetramethyl-*o*-benzoquinone (freshly prepared) and cyclopentadiene in boiling 95% EtOH give 3:4:9:10-tetramethyl-5:8-endomethylene-5:8:9:10-tetrahydronaphthalene-1:2-quinone (I), m.p. 181—182° [semicarbazone, m.p. 213—214° (decomp.)] (darkens at 207°); phenazine (II), m.p. 182—183° (from *o*-C<sub>6</sub>H<sub>4</sub>(NH<sub>2</sub>)<sub>2</sub>), which is reduced (Zn dust, aq. AcOH) to 1-hydroxy-2-keto-3:4:9:10-tetramethyl-5:8-endomethylene-1:2:5:8:9:10-hexahydronaphthalene (III), m.p. 95.5—96° (acetate, m.p. 77—78°; oxime, m.p. 184—185°), oxidised (CrO<sub>3</sub>, aq. AcOH) to (I). (III) and *o*-C<sub>6</sub>H<sub>4</sub>(NH<sub>2</sub>)<sub>2</sub> in AcOH or EtOH afford (II). Clemmensen reduction of (I) gives

a little of a product (contains O), b.p. 101—103°/14 mm.; dehydrogenation (Se at 280—300°) of this or (I) affords indefinite products. Reduction (H<sub>2</sub>, PtO<sub>2</sub> or Pd-CaCO<sub>3</sub>, EtOH) of (I) or (III) gives 1-hydroxy-2-keto-3:4:9:10-tetramethyl-5:8-endomethylene-1:2:3:4:5:8:9:10-octahydronaphthalene (IV), m.p. 82—83° (acetate, m.p. 91°; oxime, m.p. 169—170°), oxidised (CrO<sub>3</sub>, aq. AcOH) to the 1:2-diketo-derivative (V), m.p. 141—141.5° [phenazine, m.p. 181—182°, also formed from (IV)]. Reduction [H<sub>2</sub> (1800 lb.), Raney Ni, 95% EtOH, 185°] of (I), (III), or (IV) affords 1:2-dihydroxy-3:4:9:10-tetramethyl-5:8-endomethylene-3:4:5:6:7:8:9:10-octahydronaphthalene (VI), m.p. 146—147° (diacetate, m.p. 81—82°), which could not be reduced further. (VI) does not give an oxime or a phenazine; on one occasion only it was oxidised (CrO<sub>3</sub>, aq. AcOH) to the 1:2-diketodecahydro-derivative, m.p. 96—97°, indicating that it can react as the 1-hydroxy-2-ketodecahydro-form. (I) is oxidised (15% H<sub>2</sub>O<sub>2</sub>, aq. MeOH-NaOH) to β-(2-carboxy-1:2-dimethyl-3:6-endomethylene-Δ<sup>4</sup>-cyclohexenyl)-α-methyl-Δ<sup>4</sup>-butenoic acid (VII), m.p. 239—240° (decomp.) [? 4:5-dibromide (VIII), m.p. 249—250° (decomp.)], which is reduced (H<sub>2</sub>, Pd-CaCO<sub>3</sub>, aq. Na<sub>2</sub>CO<sub>3</sub>) to the *butyric acid*, m.p. 229—230°, also formed by oxidation (H<sub>2</sub>O<sub>2</sub>) of (V). Ozonolysis of

(VIII) and subsequent reductive fission gives resinous products. H. B.

**Naphthazarin and dibromonaphthazarin.**—See this vol., 428.

**Manufacture of 1:4-dihalogenoanthraquinone-2-carboxylic acids.**—See B., 1936, 182.

**9:10-Dihydroxy-9:10-di-*n*-amyl-9:10-dihydrophenanthrene and 2:2'-di-*n*-hexoyldiphenyl.** T. W. JEZERSKI and M. MACIEJEWSKI (Rocz. Chem., 1935, 15, 543—545).—Phenanthraquinone and *n*-C<sub>5</sub>H<sub>11</sub>·MgBr in Et<sub>2</sub>O yield 9:10-dihydroxy-9:10-di-*n*-amyl-9:10-dihydrophenanthrene, m.p. 102.7—104°, converted by CrO<sub>3</sub> in aq. AcOH into 2:2'-di-*n*-hexoyldiphenyl, b.p. 206°/3.5 mm. R. T.

**Grignard reagent from pinene hydrochloride.** Action of phthalic acid. R. BOUSSET (Bull. Soc. chim., 1936, [v], 3, 318—319).—*o*-Carboxybenzoylcamphane (Ag salt) has [α]<sub>D</sub> +58.92°, the *Me* ester, m.p. 72—75°, [α]<sub>D</sub> +64.7°, and the *Et* and *Pr* esters, oils, [α]<sub>D</sub> +62.95° and +60.45°, respectively. With SOCl<sub>2</sub>, HCl-MeOH, or Me<sub>2</sub>SO<sub>4</sub> the acid gives phthaloylcamphane, m.p. 216° (corr.), [α]<sub>D</sub> +194°. Other optical data are given. R. S. C.

**Grignard reaction on α-pinene oxide.** J. J. RITTER and K. L. RUSSELL (J. Amer. Chem. Soc., 1936, 58, 291—293).—Contrary to Prileschaeff and Verschuk (A., 1929, 1076), α-pinene oxide (I) and MgMeI (first in Et<sub>2</sub>O and then in C<sub>6</sub>H<sub>6</sub>) give methylcampholenol (II),  $\begin{matrix} \text{CMe} \cdot \text{CMe}_2 \\ | \\ \text{CH} - \text{CH}_2 \end{matrix} > \text{CH} \cdot \text{CH}_2 \cdot \text{CHMe} \cdot \text{OH}$ , b.p. 82—83°/4 mm., 107—108°/12 mm., also prepared from campholenaldehyde (Arbuzov, A., 1935, 1246) and MgMeI. The formation of (II) involves a ring-fission and subsequent ring enlargement. (II) is oxidised (Na<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>, dil. H<sub>2</sub>SO<sub>4</sub>) to methylcampholenone, b.p. 73—74°/4 mm. [semicarbazone, m.p. 175—176° (corr.)]. Ethyl-, b.p. 88—89°/4 mm., *n*-propyl-, b.p. 100—101°/4 mm., *n*-butyl-, b.p. 110—112°/4 mm., isobutyl-, b.p. 106—107°/4 mm., and phenyl-, b.p. 140—142°/1.3 mm., *campholenols* are similarly formed from (I) and MgRX. Ethylcampholenone has b.p. 80—81°/2 mm. [semicarbazone, m.p. 148—149° (corr.)]. H. B.

**Norborneol and norbornylene.** G. KOMPPA and S. BECKMANN (Ann. Acad. Sci. fenn., 1934, A, 39, No. 7, 9 pp.; Chem. Zentr., 1935, i, 3940).—Mostly already reported (A., 1934, 658). 2-Carbamyl-dicyclo-[1:2:2]-heptane, m.p. 205—206°, prepared from the acid in the usual way affords norbornylamine with KOH-KOBr. H. N. R.

**Borneol-isoborneol question.** Y. ASAHINA, M. ISHIDATE, and T. SANO (Ber., 1936, 69, [B], 343—348; cf. A., 1935, 625; Lipp, *ibid.*, 983).—*d*-trans-π-apo-Borneol-7-carboxylic acid, obtained by vigorous reduction of isoketopinic acid with Na and EtOH (slow reduction causes some production of isoborneol derivatives), is quantitatively converted by AcCl in C<sub>5</sub>H<sub>5</sub>N into the corresponding acetate (I), m.p. 106—107°, which with SOCl<sub>2</sub> affords *d*-trans-π-apoacetylborneol-7-carboxyl chloride, b.p. 124°/6 mm., transformed by H<sub>2</sub> in boiling xylene containing Pd-C into *d*-trans-π-apoacetylborneol-7-aldehyde [reoxidised to

(I)], the *semicarbazone*, m.p. 195°, of which is converted by NaOEt-EtOH at 150—155° into *d*-borneol (II). Similarly, *trans*- $\pi$ -apoisoacetylborneol-7-carboxylic acid, from *apocamphenecarboxylic acid* (III) by hydration according to Bertram-Walbaum, is converted successively into the corresponding *chloride*, b.p. 120°/6 mm., *trans*- $\pi$ -apoisoacetylborneol-7-aldehyde (*semicarbazone*, m.p. 197°), and *isoborneol*. *trans*- $\pi$ -apoCamphor-7-carboxylic acid is therefore a substituted camphor which, like the latter, on energetic reduction gives mainly a borneol derivative, whereas (III) is a substituted camphene passing, when hydrated, mainly into an *isoborneol* compound. Reduction of *d*-ketodihydroteresantalic acid by Na and EtOH yields the antipode of the Semmler-Bartelt lactone, m.p. 196°, and *d*-cis- $\pi$ -apoborneol-7-carboxylic acid (IV), m.p. 278°. Treatment of (IV) with AcCl in C<sub>6</sub>H<sub>5</sub>N affords the corresponding *acetate*, b.p. 155—158°/5 mm., the *chloride*, b.p. 124°/6 mm., of which is converted *d*-cis- $\pi$ -apoacetylborneol-7-aldehyde, the *semicarbazone*, m.p. 224°, of which affords (II). *r*-isoBorneol is unchanged by NaOEt-EtOH at 155°, but passes at 170—180° into borneol. H. W.

**Oxidation of bornyl acetate.** Y. ASAHINA, M. ISHIDATE, and T. TUKAMOTO (Ber., 1936, 69, [B], 349—354).—Oxidation of *l*-bornyl acetate by CrO<sub>3</sub> in AcOH-Ac<sub>2</sub>O at 80° affords unchanged material, and fractions, b.p. 115—160°/15 mm. (I), and b.p. >160°/15 mm. (II), respectively. Treatment of (I) with 10% K<sub>2</sub>CO<sub>3</sub> gives small amounts of 1:5:5-trimethylcyclopentan-2-one-4-acetic acid (III) (*semicarbazone*, m.p. 240°), and the unattacked portion is oxidised by Na<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> and dil. H<sub>2</sub>SO<sub>4</sub> to 3:6-diketocamphane, m.p. 212°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> -105.5° in abs. EtOH (*disemicarbazone*, m.p. 295°), (III), and ketocampholenic acid (IV), m.p. 130° (*semicarbazone*, m.p. 218°). (IV) is also obtained by the action of KOH-EtOH on 6-bromo-2:5-diketocamphane or 2-bromo-3:6-diketocamphane, m.p. 145°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> -152.7° in abs. EtOH, from 3:6-diketocamphane (V) and Br in CHCl<sub>3</sub>. *l*-p-Ketoborneol (VI) is oxidised by Na<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> and dil. H<sub>2</sub>SO<sub>4</sub> at 100° to (IV) and (V); under like conditions, *l*-p-diketocamphane is largely unattacked. Catalytic hydrogenation (Pd-C in AcOH) of (IV) gives optically inactive 1:5:5-trimethylcyclopentan-3-one-4-acetic acid, m.p. 90° (*semicarbazone*, m.p. 229°). (II) when oxidised with H<sub>2</sub>O<sub>2</sub> in alkaline solution and then heated with alkali yields (VI) and *d*-2-hydroxycamphoric acid (VII), m.p. 165°, [ $\alpha$ ]<sub>D</sub><sup>23</sup> +7.8° in abs. EtOH (*Me*<sub>3</sub> ester, b.p. 150—151°/11 mm., m.p. 46°). Synthesis of (VII) is effected by treating *l*-p-ketobornyl acetate, m.p. 78°, [ $\alpha$ ]<sub>D</sub><sup>24</sup> -87.9° in abs. EtOH, with SeO<sub>2</sub> in Ac<sub>2</sub>O at 130—140°, thus yielding 6-acetoxycamphor-2:3-quinone, m.p. 109°, [ $\alpha$ ]<sub>D</sub><sup>23</sup> -191.4° in abs. EtOH, which is oxidised by NaOH and H<sub>2</sub>O<sub>2</sub> to (VII). 2-Acetoxycamphor-5:6-quinone, m.p. 109°, [ $\alpha$ ]<sub>D</sub><sup>23</sup> +188.5° in abs. EtOH, is oxidised to 1-2-hydroxycamphoric acid, m.p. 165°, [ $\alpha$ ]<sub>D</sub><sup>23</sup> -8.0° in abs. EtOH. Oxidation of (VII) affords *d*-1:5:5-trimethylcyclopentan-2-one-4-carboxylic acid, m.p. 122°, [ $\alpha$ ]<sub>D</sub><sup>23</sup> +163.74° in abs. EtOH (*semicarbazone*, m.p. 215°; *Me* ester, m.p. 41°); the corresponding *l*-acid has m.p. 122°, [ $\alpha$ ]<sub>D</sub><sup>23</sup> -166.8° in abs. EtOH (*semicarbazone*, m.p. 215°), and the *r*-acid has m.p. 117°. H. W.

**New camphor derivative, "ketobornylene."** Y. ASAHINA, M. ISHIDATE, and T. TUKAMOTO (Ber., 1936, 69, [B], 355—357).—6-Acetoxycamphorquinone with N<sub>2</sub>H<sub>4</sub>·H<sub>2</sub>O in hot EtOH gives  $\alpha$ - (I), m.p. 175°, and  $\beta$ - (II), m.p. 99°, -6-acetoxycamphorquinone-3-monohydrazone. (I) with yellow HgO in boiling C<sub>6</sub>H<sub>6</sub> affords 3-diazo-6-acetoxycamphor, m.p. 120°, also obtained more slowly from (II); when distilled with Cu-bronze it yields 6-acetoxy- $\beta$ -pericyclocamphan-2-one (III), b.p. 145°/18 mm., hydrolysed to 6-hydroxy- $\beta$ -pericyclocamphan-2-one (IV), m.p. 234°. (III) or (IV) with HBr-AcOH at room temp. gives 5-bromo-6-hydroxycamphor, m.p. 123°, transformed by Zn dust and alkali into (IV) and by Zn dust and AcOH at 100° into *keto-bornylene* [dehydrocamphor] (V), m.p. 148°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> -735° in abs. EtOH [*semicarbazone*, m.p. 234° (decomp.)], which immediately reduces cold KMnO<sub>4</sub> and slowly decolorises Br in AcOH. Catalytic hydrogenation (Pd-C in AcOH) of (V) gives *d*-camphor. H. W.

**Removal of water from camphenilol, 4-methylcamphenilol, and 4-methylborneol. Santene displacement and Nametkin transformation.** G. KOMPPA and G. A. NYMAN (Ber., 1936, 69, [B], 334—340).—Ozonisation of camphenilene obtained by heating camphenilol (I) with KHSO<sub>4</sub> leads to *apocyclene* (II) unattacked by O<sub>3</sub>, and santene diketone. Dehydration of (I) takes place partly by pinacolin transformation giving santene and partly by direct loss of H<sub>2</sub>O and subsequent ring-closure to (II). Similarly the "4-methylcamphenilene" obtained from 4-methylcamphenilol is shown to be a mixture of *epicyclene*, m.p. 116—117°, and 1-methylsantene. The relative proportion of the hydrocarbons appears to depend on the mode of dehydration. Ozonisation of 4-methylcamphene (III) in AcOH gives, as unattacked portion, 4-methyltricyclene (IV), m.p. 109—110° (also obtained by oxidation of 4-methylcamphorhydrazide with HgO); 4-methylcamphenilone, hydroxy-3-methylcamphenilonolactone, and trimethylnorcampholide are also isolated. These normal products are accompanied by considerable amounts of *dl*-fenchone (V); apparently (III) becomes partly hydrated, and the acetate thus produced suffers the Nametkin transformation and subsequent loss of AcOH. 1-Methylcamphene is thus produced, which is ozonised to (V). Elimination of H<sub>2</sub>O from 4-methylborneol occurs therefore in three directions. H. W.

**Organic catalysts. XII. Asymmetric main valency catalysis.** I. W. LANGENBECK and G. TRIEM (Ber., 1936, 69, [B], 248—250).—*d*-Camphoglyoxylic acid (I) has [ $\alpha$ ]<sub>D</sub><sup>20</sup> +255.1° in *N*-NaOH. *dl*-Camphoglyoxylic acid (II), m.p. 84—85° [oxime (+1H<sub>2</sub>O), m.p. 159°], is obtained from *dl*-camphor, Et<sub>2</sub>C<sub>2</sub>O<sub>4</sub>, and Na wire in ligroin. (I) and *dl*-alanine (III) at 150° afford small amounts of *d*-hydroxymethylenecamphor, [ $\alpha$ ]<sub>D</sub><sup>20</sup> +183° in EtOH. (II) and (III) yield *dl*-hydroxymethylenecamphor, whereas (II) and *l*-alanine give a slightly levorotatory product. If *l*-leucine is used, the product appears to be optically

inactive. The stereochemical specificity of the carb-oxylase model is thus established. H. W.

**Chios turpentine.** E. EMMANUEL (Pharm. Acta Helv., 1935, 10, 12—22; Chem. Zentr., 1935, i, 3856).—The following are isolated from the resin of *Pistacia terebinthus*, L.: *terminthic acid*,  $C_{14}H_{20}O_2$ , m.p. 136—137°; *terminthinic acid*,  $C_{16}H_{24}O_4$ , m.p. 123.5—124.1°, monobasic (EtOH-insol. *Pb* salt); *termintholic acid*, m.p. 101.5—102.1°, monobasic (EtOH-sol. *Pb* salt); *termintholinic acid*,  $C_{22}H_{34}O_3$ , m.p. 127.5—128°, monobasic; an *etheral oil*,  $d_{15}^{20} 0.8695$ ,  $n_D^{20} 1.4668$ ,  $[\alpha] +33.5^\circ$ , separable into two fractions, b.p. 157—165° and 165°—190°; a *resin* and a *bitter principle*. H. N. R.

**Polyterpenes and polyterpenoids. C. Transformations in rings A and E of oleanolic acid. Carbon skeleton of pentacyclic triterpenes.** L. RUZICKA and K. HOFMANN (Helv. Chim. Acta, 1936, 19, 114—128).—Oxidation of acetyloleanolic acid (I) by  $CrO_3$  in  $AcOH-H_2SO_4$  gives the *substance* (II), m.p. 230°, which could not be obtained homogeneous; its formula and the function of the O atoms are

established by its conversion into the corresponding *anhydride* (III), m.p. 294—295°, (dehydrogenated by Se at 350° to 2:7- $C_{10}H_6Me_2$ ), its transformation by  $CH_2N_2$  or from the *Ag*<sub>2</sub> salt and MeI in  $Et_2O$  into the *Me*<sub>2</sub> ester (IV), m.p. 203—204°, or (+1MeOH) m.p. 178—179°, and its hydrolysis to the *lactone-carboxylic acid*,  $C_{30}H_{46}O_7$ , m.p. 270° (decomp.), converted by successive treatment with  $CH_2N_2$  and  $Ac_2O$  into (IV).

Hydrolysis of (IV) with  $KOH-MeOH$  gives the *Me H isolactonedicarboxylate*,  $C_{31}H_{48}O_7$ , m.p. 300—304°, converted by  $CH_2N_2$  into the corresponding *Me*<sub>2</sub> ester (V), m.p. 213—214° (also +1MeOH) (*Ac* derivative, m.p. 273—274°), which is very resistant to alkaline hydrolysis. Oxidation of (V) by  $CrO_3$  (=1.5O) in  $AcOH$  gives the *Me*<sub>2</sub> ester of the *ketoisolactonedicarboxylic acid*, m.p. 219—220° [*oxime*, m.p. 257—258° (decomp.); *OH·CH*: derivative]. *Me* oleanolate is oxidised by  $CrO_3$  to *Me oleanonate*, m.p. 156—157° [*oxime*, m.p. 218—219° (decomp.); *OH·CH*: derivative, m.p. 197—199°]. The above results and a review of the lit. suggest the structure (VI) for oleanolic acid. H. W.

**α-Tocopherol from wheat-germ oil.**—See this vol., 531.

**The crystalline acid of Canada balsam.** F. TROST (Annali Chim. Appl., 1936, 26, 38—42).—*Canadolic acid* (A., 1900, i, 678), new formula  $C_{20}H_{30}O_2$ ,  
K K

new m.p. 165—168°,  $[\alpha]_D^{20} -91^\circ$  in  $EtOH$ , is an isomeride of abietic acid. It is dehydrogenated (Se) to retene, gives a *compound*, m.p. 226°, with maleic anhydride, and is converted by  $AcOH$  at 100° into Steele's abietic acid (A., 1922, i, 739). E. W. W.

**Plant cardiac poisons. VIII. Convallatoxin.** R. TSCHESCHE and W. HAUPT (Ber., 1936, 69, [B], 459—464; cf. Karrer, A., 1929, 684).—Convallatoxin (I), m.p. 238—239°, or (hydrated) m.p. 225°, is  $C_{29}H_{42}O_{10}$ . It contains two double linkings, one of which is saturated with great difficulty. (I) is hydrolysed with difficulty by acids to *l*-rhamnose and monoanhydroconvallatoxinigenin, isolated as the *benzoate* (II), m.p. 279—281°,  $[\alpha]_D^{20} +22.2^\circ$  in  $CHCl_3$ . In addition to the three double linkings of the  $C_6H_6$  group, (II) contains three double linkings, one of which is very resistant towards saturation. Its absorption curve very closely resembles that of anhydrouzarigenin benzoate. (II) contains two, probably *tert.* OH (Zerevitinov). Convallatoxinigenin (III) therefore contains one *sec.* and two *tert.* OH. Like (II) it does not

react with ketonic reagents. The positive Legal test establishes the presence of an unsaturated side-chain which is opened by alkali, thus allowing the equiv. to be determined.

Acidification of the alkaline solution leads to α-, m.p. 256—258°, and β-, m.p. 289—290°, *isoconvallatoxin*. Assuming that (III) contains the same C skeleton as digitoxigenin, strophanthidin, and uzarigenin, the constitution shown explains satisfactorily the behaviour of (III). The disposition of the double linkings and OH is discussed in detail. H. W.

**Phytosterol and resin of *Fabiana denudata*.**—See this vol., 533.

**Punar-Nava (*Boerhaavia diffusa*).**—See this vol., 533.

**Two disputed properties of nitrolignin.** K. KÜRSCHNER (Zellstoff-Faser, 1935, 32, 17—19; Chem. Zentr., 1935, ii, 2987).—The non-cryst. nature and the presence of oximino-keto-compounds are refuted (cf. Nijhofs, B., 1934, 395). H. N. R.

**Action of benzaldehyde on lignin.** N. I. NIKITIN and I. M. ORLOVA (J. Appl. Chem. Russ., 1935, 8, 1402—1409).—The product pptd. by  $Et_2O$  or light petroleum from  $PhCHO$  solutions (prepared by heating at 150—160° for 7 hr.) of Willstätter lignin has a higher C and a lower OMe content than the original material. Since this undergoes similar changes when heated alone, it is not possible to decide whether the analytical data are interpretable on the basis of condensation with  $PhCHO$  or of thermal transformation; possibly both processes enter.

R. T.  
**Lignin and related compounds. XXIII. Preparation and methylation of spruce lignin-sulphonic acids. XXIV. Formation of vanillin from waste sulphite liquor. XXV. Mechanism**

of vanillin formation from spruce lignin-sulphonic acids in relation to lignin structure. G. H. TOMLINSON II and H. HIBBERT (J. Amer. Chem. Soc., 1936, **58**, 340—345, 345—348, 348—353).—XXIII. Spruce wood meal (extracted with EtOH- $C_6H_6$ ) (I) is heated with aq.  $Ca(HSO_3)_2 + SO_2$  at 125° and the liquor treated with  $CaCl_2$ , which salts out  $Ca$   $\alpha$ -ligninsulphonate (II);  $Ca$   $\beta$ -ligninsulphonate (III) (37% of total salt) (Ca 5, S 10.4, OMe 10.45%) is isolated from the mother-liquors through the Pb salt. (II) is separated by further salting out ( $CaCl_2$ ) into fractions (IIa) (19%) (Ca 3.5, S 9.4, OMe 11.2%) and (IIb) (44%) (Ca 3.8, S 9.6, OMe 11.35%). All the salts are purified by dialysis and subsequent pptn. from aq. EtOH by EtOH-Et<sub>2</sub>O. The liquor from (I) and aq.  $KHSO_3 + SO_2$  at 110° with quinoline hydrochloride gives (cf. Hägglund, B., 1933, 584; Freudenberg *et al.*, A., 1935, 861) a quinoline salt, subsequently converted into K ligninsulphonate (IV) (70%) (K 3.7, S 5.4%); a K salt (V) (30%) (K 2.7%) is isolated from the mother-liquors (A) through the Pb salt. (V) is separable into K salts (Va) (16%) (K 5, S 6.6%) and (Vb) (14%) (K 5.8, S 5.6%) by successive treatment of (A) with  $\beta$ - $C_{10}H_7$ -NH<sub>2</sub> and Pb(OAc)<sub>2</sub> and subsequent conversion into the K salts. The efficiency of the following reagents as precipitants is  $NaCl < CaCl_2 < quinoline, isoamylamine < \beta$ - $C_{10}H_7$ -NH<sub>2</sub> < Pb(OAc)<sub>2</sub> (cf. Hägglund, *loc. cit.*). (IV) and (V) (in aq. COMe<sub>2</sub>) are methylated [ $Me_2SO_4$  (1 mol.), 30% KOH (1.1 mols.), 20°] to fully methylated products (VI) and (VII), respectively, containing 30 and 31.6% OMe (calc. on K- and  $SO_3H$ -free basis), respectively, without loss of S.

XXIV. In agreement with Kürschner (cf. B., 1928, 292), vanillin (VIII) is obtained in yields of 3.44—7.27% (based on lignin content) when waste sulphite liquor is boiled with NaOH, KOH, or (less satisfactorily)  $Ba(OH)_2$ ; the mixture is acidified ( $H_2SO_4$ ), extracted with  $CHCl_3$ , and (VIII) is then isolated with  $NaHSO_3$  and subsequently determined as the *m*-nitrobenzoylhydrazone. The effect of the original cooking treatment on the yield of (VIII) is investigated; max. yields are obtained when sulphite liquors containing a relatively high proportion of "free"  $SO_2$  are used at 110—125° (prolonged heating at such temp. having little effect on the yield).

XXV. The yields of (VIII), calc. on metal- and  $SO_3H$ -free basis, obtained when the following salts (see Part XXIII) are boiled with 19.4% (wt.) NaOH in  $N_2$  for 12 hr. are: (IIa) 6.1, (IIb) 6.6, (III) 8.4, (IV) 6.4, (Va) 8.6, (Vb) 7.1. The other fission products contain less S but approx. the same OMe as the original compounds, indicating that a small non-methylated aliphatic fragment is also removed during the hydrolysis. Veratraldehyde (*m*-nitrobenzoylhydrazone, m.p. 221—223°) is formed in yields of 2.35 and 2.76%, respectively, from (VI) and (VII) with boiling 3.8% NaOH. The presence of the 4:3-(OH)(OMe) $C_6H_3$  group in spruce-lignin is thus proved. Unsulphonated lignin does not similarly yield (VIII). It is suggested that a group such as 4:3-(OH)(OMe) $C_6H_3$ -CH( $SO_3H$ )-CH<sub>2</sub> is hydrolysed ( $SO_3H$  replaced by OH), and that the resulting product gives (VIII) by a reversed aldol reaction;

evidence in support of this view (cf. Freudenberg *et al.*, *loc. cit.*) is given. H. B.

**Aesculus saponins and their sugar-free derivatives.** E. BUREŠ and K. BABOR, jun. (Časopis českoslov. Lék., 1935, **15**, 3—8, 25—34; Chem. Zentr., 1935, i, 3936).—Three saponins are isolated from chestnut seeds: *saponin B*, decomp. 80—120°; *saponin C*, m.p. 150° (decomp.), and *saponin A*, which, when purified by repeated pptn. from EtOH and by dialysis, has m.p. 190—194° (decomp.) and composition  $C_{24}H_{38}O_8(OH)_7$  (Br-derivative,  $C_{24}H_{45}O_{16}Br$ , decomp. 130°; *hepta-acetate*, m.p. 155—160°). The latter is hydrolysed to the prosapogenin, aescin, decomp. 211—225° [Br-derivative, m.p. 217° (decomp.); *penta-acetate*, m.p. 169—170°], which is further hydrolysed to aescigenin, m.p. 179—186°. H. N. R.

**Constituents of "Senso." IV. Grignard cleavage of methyl deacetyltetrahydro- $\psi$ -bufotalinate.** S. IKAWA (J. Pharm. Soc. Japan, 1935, **55**, 195—217).—Grignard cleavage of Me deacetyltetrahydro- $\psi$ -bufotalinate yields *deacetyltetrahydro-dimethyl- $\psi$ -bufotalene-A*,  $C_{26}H_{44}O_4$ , m.p. 125—126° (*triacetate*, m.p. 98—100°), which is oxidised to *deacetyltetrahydro- $\psi$ -bufotalone-A*,  $C_{23}H_{38}O_5$ , m.p. 158—159° (*oxime*, m.p. 124—125°; *p*-nitrophenylhydrazone, m.p. 158—159°; *triacetate*, m.p. 163—164°). On further Grignard cleavage this yields *deacetyltetrahydromethyl- $\psi$ -bufotalene-B* (I),  $C_{24}H_{40}O_4$ , m.p. 120—121°, whilst oxidation affords a OH-aldehyde, *deacetyltetrahydro- $\psi$ -bufotal*,  $C_{21}H_{34}O_5$ , m.p. 145—147°. (I), when heated in xylene, gives *deacetyltetrahydromethyl- $\psi$ -bufotalindiene*,  $C_{24}H_{38}O_3$ , m.p. 118—120°, oxidised to *deacetyltetrahydro- $\psi$ -bufotalene-B*,  $C_{20}H_{32}O_4$ , m.p. 127—129° (*p*-nitrophenylhydrazone, m.p. 172—175°; *diacetate*, m.p. 115—117°); with  $AcO_2H$  this yields a substance,  $C_{20}H_{32}O_5$ , m.p. 135—136° (*p*-nitrophenylhydrazone, decomp. 167—169°), whilst Grignard cleavage affords *deacetyltetrahydromethyl- $\psi$ -bufotalene-C*,  $C_{21}H_{34}O_3$ , m.p. 135—136°. This is oxidised to *deacetyltetrahydro- $\psi$ -bufotalone-C*,  $C_{18}H_{28}O_4$ , m.p. 117—119°, which, on Grignard cleavage, affords *deacetyltetrahydromethyl- $\psi$ -bufotalene-D*,  $C_{19}H_{30}O_3$ , m.p. 102—103°, oxidised to *deacetyltetrahydromethyl- $\psi$ -bufotalene oxide*,  $C_{19}H_{30}O_4$ , m.p. 159—160°. This latter, with  $O_3$ , yields *deacetyltetrahydromethyl- $\psi$ -bufotalonal*,  $C_{19}H_{30}O_5$ , m.p. 110—111° (*mono*-, m.p. 105—106°, and *di*-, m.p. 115—117°, *acetate*; *oxime*, decomp. 126—127°), which, with  $AcO_2H$ , affords *deacetyltetrahydromethyl- $\psi$ -bufotalonic peroxide*,  $C_{38}H_{60}O_{14}$ , decomp. 193—195°, yielding, with dil. NaOH, *deacetyltetrahydromethyl- $\psi$ -bufotalonic acid*,  $C_{19}H_{30}O_6$ , m.p. 184—185°. CH. ABS. (r)

**Identity of evodin, dictamnolactone, and obakulactone.** A. FUJITA, T. TAKU, and N. KUTANI (J. Pharm. Soc. Japan, 1935, **55**, 248—251).—The identity is indicated by m.p. and  $[\alpha]$ . CH. ABS. (r)

**Bilifuscin.**—See this vol., 501.

**Preparation of tetrahydrofurfuryl bromide and its reaction with magnesium.** R. ROBINSON and L. H. SMITH (J.C.S., 1936, 195—196).—Contrary to Paul (A., 1933, 954) the product of the interaction

of Mg with tetrahydrofurfuryl bromide (I) (improved prep.) in pure dry  $\text{Et}_2\text{O}$ , wet and commercial  $\text{Et}_2\text{O}$ , and in  $\text{Et}_2\text{O}$ - $\text{EtOH}$  (6:1) is always  $\Delta^8$ -penten- $\alpha$ -ol, only traces of tetrahydrofuran and of recovered (I) being obtained.

J. W. B.

**Hydroxyfurans. I. 3-Hydroxy-2:4:5-triphenylfuran.** E. P. KOHLER, F. H. WESTHEIMER, and M. TISHLER (J. Amer. Chem. Soc., 1936, 58, 264—267).—Successive treatment of 3-acetoxy-2:4:5-triphenylfuran (I) (Thiele, A., 1898, i, 469) with  $\text{MgMeI}$  and cold dil.  $\text{H}_2\text{SO}_4$  gives 3-hydroxy-2:4:5-triphenylfuran (II) (not isolable), which has no phenolic properties, but resembles an active open-chain enol. (II) (in  $\text{Et}_2\text{O}$ ) and  $\text{O}_2$  afford the 2:3-peroxide (III), decomp. about  $120^\circ$ . Hydrolysis (dil.  $\text{H}_2\text{SO}_4$  in  $\text{AcOH}$  and  $\text{N}_2$ ) of (I) gives 3-keto-2:4:5-triphenyl-2:3-dihydrofuran, m.p.  $112^\circ$  [the ketonic form of (II)], which is only slowly oxidised ( $\text{O}_2$ ) to (III). The deep yellow colour of (II) precludes direct titration with  $\text{Br}$ ; indirect titration is vitiated owing to the production of (III). Reduction ( $\text{H}_2$ ,  $\text{PtO}_2$ ,  $\text{EtOAc}$ ) of (III) gives 2-hydroxy-3-keto-2:4:5-triphenyl-2:3-dihydrofuran (IV), m.p.  $191^\circ$  [*Me ether* (V), m.p.  $138^\circ$ , formed by the action of  $\text{MeOH}$ - $\text{H}_2\text{SO}_4$ ; *Et ether*, m.p.  $111^\circ$ ; acetate (VI), m.p.  $138$ — $139^\circ$ ], converted by  $\text{Br}$  into 2-bromo-3-keto-2:4:5-triphenyl-2:3-dihydrofuran (VII), m.p.  $154^\circ$  [decomp. yielding (VIII) (below)], which is most conveniently prepared from (I) and  $\text{Br}$  in boiling  $\text{CCl}_4$ . (VII) is converted by  $\text{MeOH}$  into (V). Reduction of (III) by methods other than the above affords (IV) and 3:3'-diketo-2:4:5:2':4':5'-hexaphenyl-2:3:2':3'-tetrahydro-2:2'-difuryl (VIII),  $272$ — $274^\circ$  [also obtained from (VII) and Cu-bronze in  $\text{C}_6\text{H}_6$ ]. (IV) and  $\text{SOCl}_2$  give 2-chloro-3-keto-2:4:5-triphenyl-2:3-dihydrofuran, m.p.  $149$ — $150^\circ$ . (IV) and  $\text{Na}$  in  $\text{Et}_2\text{O}$  give a Na derivative, which with  $\text{CO}_2$ ,  $\text{AcCl}$ , and  $\text{MeI}$  (or  $\text{Me}_2\text{SO}_4$ ) affords (IV), (VI), and (V), respectively; treatment with  $\text{Br}$  gives  $\gamma$ -bromo- $\alpha\beta\delta$ -triketo- $\alpha\gamma\delta$ -triphenylbutane, m.p.  $111^\circ$ , which is reduced catalytically to (IV).

H. B.

#### Occurrence of furan derivatives in volatile oils.

**II.  $\alpha$ -Clausenan and di- $\alpha$ -clausenan.** B. S. RAO and K. S. SUBRAMANIAM (Proc. Indian Acad. Sci., 1935, 2, A, 574—579).— $\alpha$ -Clausenan (I) (A., 1935, 134) combines with maleic anhydride to give the anhydride  $\text{C}_{14}\text{H}_{14}\text{O}_4$ , m.p.  $85^\circ$ , of the acid  $\text{C}_{14}\text{H}_{16}\text{O}_5$ , m.p. ( $+9\text{H}_2\text{O}$ )  $98^\circ$ , (anhyd.)  $248^\circ$ . With  $\text{HgCl}_2$  (I) gives the substance  $\text{C}_{10}\text{H}_{10}\text{O}(\text{HgCl})_2$ . (I) is oxidised by  $\text{FeSO}_4$  to a mixture of  $\alpha$ -clausenyl alcohol,  $\text{C}_{10}\text{H}_{14}\text{O}_2$ , b.p.  $89$ — $90^\circ/30$  mm. (*Ac* derivative, b.p.  $98$ — $102^\circ/30$  mm.; phthaloyl derivative), a primary alcohol, with an isomeric tert.-alcohol, b.p.  $<93^\circ/30$  mm., dehydrated by  $\text{Na}$  to (I). With  $\text{KMnO}_4$ , (I) yields a ketone,  $\text{C}_9\text{H}_{10}\text{O}_2$ , b.p.  $95$ — $96^\circ/55$  mm. (*oxime*), with traces of an acid (*anilide*, m.p.  $154^\circ$ ).  $\text{HNO}_3$  (*d* 1.12) has little action on (I) at  $<30^\circ$ ; with fuming  $\text{HNO}_3$  in  $\text{AcOH}$ , a nitroketone,  $\text{C}_9\text{H}_9\text{O}_4\text{N}$ , charring at  $130^\circ$ , is formed.  $\text{HCO}_2\text{H}$  at  $0^\circ$  gives a resinous product, b.p.  $240^\circ/2$  mm., and no di- $\alpha$ -clausenan (II) (*loc. cit.*). (II) does not combine with maleic anhydride; with fuming  $\text{HNO}_3$  it yields a substance,  $\text{C}_{18}\text{H}_{18}\text{O}_8\text{N}_2$ , charring at  $140^\circ$ , and with  $\text{HgCl}_2$  the compound  $\text{C}_{20}\text{H}_{22}\text{O}_2(\text{HgCl})_2$ . Na

in  $\text{EtOH}$  reduces (II) to a compound, b.p.  $100$ — $101^\circ/4$  mm.

E. W. W.

**Passage from the sugar to the pyran and pyrrole series. Methylisopyromucic acid.** E. VOTOCEK and S. MALACHTA (Coll. Czech. Chem. Comm., 1936, 8, 66—78).—Distillation of thamnono- (I), *d*-fucono-, and (probably) *d*-glucono-lactone, and  $\alpha\beta\alpha'\beta'$ -tetrahydroxy- $\alpha$ -methyladipilactone gives 3-hydroxy-6-methyl-1:2-pyrone ("methylisopyromucic lactone"), m.p.  $120$ — $121^\circ$ , which gives a green colour with  $\text{FeCl}_3$ , reduces Fehling's solution and  $\text{AgNO}_3$ , and gives a *Br*-, m.p.  $147^\circ$ , and *Bz* derivative, m.p.  $121$ — $122^\circ$ . Peligot's sugar decomposes when distilled. Ba fuconate gives an unidentified aldehyde. (I) is resinified by  $\text{HCl}$  at  $150^\circ$ . Distillation of  $(\text{NH}_4)_2\alpha\beta\alpha'\beta'$ -tetrahydroxy- $\alpha$ -methyladipate or  $\text{NH}_4$  rhamnionate with  $(\text{NH}_4)_2\text{CO}_3$ , best in glycerol under  $\text{NH}_3$ , gives 2-methylpyrrole.

R. S. C.

**Synthetical experiments in the chromone group. XVIII. Demethylation with aluminium chloride.** K. C. GULATI and K. VENKATARAMAN (J.C.S., 1936, 267—269).—Demethylation of 2:4:6-trimethoxyacetophenone (improved prep.) with  $\text{AlCl}_3$  in  $\text{PhCl}$  gives the 2:4-dihydroxy-6-methoxy-compound (Sonn *et al.*, A., 1925, i, 1267) (4-benzyl ether, m.p.  $72^\circ$ ). 2-Benzoyloxy-4:6-dimethoxyacetophenone, m.p.  $91^\circ$  (from  $\text{BzCl}$ - $\text{C}_2\text{H}_5\text{N}$  and the 2-OH-compound), with  $\text{NaNH}_2$  in  $\text{Et}_2\text{O}$  and treatment of the diketone with 20%  $\text{H}_2\text{SO}_4$ - $\text{EtOH}$ , affords chrysin  $\text{Me}_2$  ether (I), m.p.  $143^\circ$  (lit., m.p.  $115$ — $117^\circ$ ), also obtained from chrysin (II)- $\text{Me}_2\text{SO}_4$ - $\text{COMe}_2$ -20%  $\text{NaOH}$ , or by the action of 20%  $\text{H}_2\text{SO}_4$ - $\text{EtOH}$  on the product (containing 2-hydroxy-4:6-dimethoxy-dibenzoylmethane) of the action of  $\text{AlCl}_3$  on 2:4:6-trimethoxybenzoylacetophenone (III) in  $\text{PhNO}_2$ . (I) with  $\text{AlCl}_3$ - $\text{PhNO}_2$  at  $100^\circ$  affords tecto-chrysin (IV), but when heated with solid  $\text{AlCl}_3$ , (II) and (IV) are obtained. (III) with  $\text{HI}$  (*d* 1.7)- $\text{Ac}_2\text{O}$  also gives (II) and (IV). The crude product of interaction of phloracetophenone and  $\text{Bz}_2\text{O}$ , with  $\text{Me}_2\text{SO}_4$ - $\text{COMe}_2$ -10% aq.  $\text{NaOH}$  gave, in one experiment, (I) and its 3-*Bz* derivative, m.p.  $212^\circ$ , and, in another, (II) and 2-hydroxy-4:6-dibenzoyloxy- $\omega$ -benzoylacetophenone, m.p.  $157^\circ$ . (II) with either  $\text{CH}_2\text{PhCl}$ - $\text{COMe}_2$ - $\text{K}_2\text{CO}_3$  or  $\text{CH}_2\text{PhBr}$ -aq.  $\text{EtOH}$ - $\text{KOH}$  affords 5-hydroxy-7-benzoyloxy-6-benzylflavone, m.p.  $205^\circ$ .

J. W. B.

**Hydroxy-carbonyl compounds. X. Coumarins and chromones from *m*-4-xyleneol.** D. G. FLYNN and A. ROBERTSON (J.C.S., 1936, 215—217).—Condensation of *m*-4-xyleneol (I) with  $\text{CHRAc}\cdot\text{CO}_2\text{Et}$  gives (a) coumarins by Pechmann's method, and (b) chromones by that of Simonis, when  $\text{R}=\text{H}$ ,  $\text{Me}$ ,  $\text{Et}$ : when  $\text{R}=\text{CH}_2\text{Ph}$  or with  $\text{CH}_2\text{Bz}\cdot\text{CO}_2\text{Et}$  (b) fails to give condensation products. (I) and  $\text{CH}_2\text{Ac}\cdot\text{CO}_2\text{Et}$  with 86%  $\text{H}_2\text{SO}_4$  give 4:6:8-trimethylcoumarin (II), converted (Canter *et al.*, A., 1931, 1069) into 2-methoxy- $\beta$ :3:5-trimethylcinnamic acid, m.p.  $139^\circ$ , oxidised to 2-methoxy-3:5-dimethylacetophenone, b.p.  $134$ — $135^\circ/21$  mm. (*semicarbazone*, m.p.  $193^\circ$ ), also obtained by methylation of the 2-OH-compound (III). 3:4:6:8-Tetramethyl- (IV), 4:6:8-trimethyl-3-ethyl-, m.p.  $112.5$ — $113^\circ$ , 4-phenyl-6:8-dimethyl-, m.p.  $111^\circ$ , and 3-benzyl-4:6:8-trimethyl-, m.p.  $112$ — $113^\circ$ , -coumarin are similarly obtained,

whence 2-methoxy- $\alpha$ : $\beta$ :3:5-tetramethyl-, m.p. 139.5—140°, and - $\beta$ :3:5-trimethyl- $\alpha$ -ethyl-, m.p. 112°, cinnamic acid are prepared. (III) with EtOAc-Na at 100° gives 2-hydroxy- $\omega$ -acetyl-3:5-dimethylacetophenone, m.p. 85°, cyclised (AcOH-HCl) to the chromone, m.p. 125° [also from (I)-CH<sub>2</sub>Ac-CO<sub>2</sub>Et-P<sub>2</sub>O<sub>5</sub>], condensed with piperonal to give 2-(3':4'-methylenedioxystyryl)-6:8-dimethylchromone, m.p. 195°. The propionate of (I) with AlCl<sub>3</sub> affords 2-hydroxy-3:5-dimethylpropiophenone, m.p. 52—53°, converted by Ac<sub>2</sub>O-NaOAc at 180° into 2:3:6:8-tetramethylchromone, m.p. 136—137° [also from (I) and CHMeAc-CO<sub>2</sub>Et], whence 2-(3':4'-methylenedioxystyryl)-3:6:8-trimethylchromone, m.p. 196° is obtained. 2-Hydroxy-3:5-dimethyl-n-butyrophenone, b.p. 145—150°/30 mm., m.p. 30° [from the butyrate, b.p. 132—133°/17.5 mm. of (I)], 2:6:8-trimethyl-(V), m.p. 112.5°, and 2-(3':4'-methylenedioxystyryl)-6:8-dimethyl-, m.p. 202—203°, 3-ethylchromone, are obtained similarly. (III) with Ac<sub>2</sub>O-NaOAc at 170° affords (V), its 3-Ac derivative (isolated at its oxime, m.p. 119°), and (II). (III) and (EtCO)<sub>2</sub>O-EtCO<sub>2</sub>Na give (IV) and 3-propionyl-6:8-dimethyl-2-ethylchromone (as its oxime, m.p. 93°); (III) with BzO-NaOBz affords 3-benzoyl-6:8-dimethylflavone, m.p. 191—192°. With EtCO<sub>2</sub>Et and Na (III) gives 6:8-dimethyl-2-ethylchromone, m.p. 109—110°. J. W. B.

**Reaction between duroquinone and sodio-malonic ester.** III. Reduction products. L. I. SMITH and R. O. DENYES (J. Amer. Chem. Soc., 1936, 58, 304—309).—The Et ester (I), m.p. 183—184°, of 6-hydroxy-5:7:8-trimethylcoumarin-3-carboxylic acid (II), m.p. 256—258° (decomp.) (A., 1926, 836), is reduced (H<sub>2</sub>, PtO<sub>2</sub>, EtOH) to Et 6-hydroxy-5:7:8-trimethyl-3:4-dihydrocoumarin-3-carboxylate (III), m.p. 104—105° [acetate, m.p. 116—117°, also prepared by reduction of the acetate of (I)], which is hydrolysed (20% HCl in COMe<sub>2</sub>) to 6-hydroxy-5:7:8-trimethyl-3:4-dihydrocoumarin (IV), m.p. 173—174° (acetate, m.p. 147—148°), also obtained by reduction (as above) of (II). (IV) and Me<sub>2</sub>SO<sub>4</sub> in MeOH-KOH afford  $\beta$ -2:5-dimethoxy-3:4:6-trimethylphenylpropionic acid, m.p. 132—133° (amide, m.p. 188—189°), whilst (IV) and aq. MeOH-NaOH in C<sub>6</sub>H<sub>6</sub> give trimethyl- $\beta$ -carboxyethyl-p-benzoquinone (V), m.p. 113—114°, which is reduced (Zn dust, aq. AcOH) to (IV). 2:4:5-C<sub>6</sub>H<sub>2</sub>Me<sub>3</sub>:CH:CH-CO<sub>2</sub>H, m.p. 154—155°, best prepared from 2:4:5-C<sub>6</sub>H<sub>2</sub>Me<sub>3</sub>:CHO, Ac<sub>2</sub>O, and NaOAc at 170—180° in N<sub>2</sub>, is reduced to 2:4:5-C<sub>6</sub>H<sub>2</sub>Me<sub>3</sub>:CH<sub>2</sub>:CH<sub>2</sub>-CO<sub>2</sub>H [Me ester (VI), b.p. 125—127°/4 mm.], which with HNO<sub>3</sub> (d 1.52) in CHCl<sub>3</sub>+conc. H<sub>2</sub>SO<sub>4</sub> gives  $\beta$ -3:6-dinitro-2:4:5-trimethylphenylpropionic acid, m.p. 206—207° [amide, m.p. 215—216°; Me ester, m.p. 164.5—165°, also prepared by similar nitration of (VI)]. This is reduced (SnCl<sub>2</sub>, HCl, AcOH) to 6-amino-5:7:8-trimethyl-3:4-dihydrocarbostyryl, m.p. 223—224° (Ac derivative, m.p. 320°), which is oxidised (FeCl<sub>3</sub>, dil. HCl) to (V). Reduction (Zn, AcOH) of (I) gives (III), Et 6:6'-dihydroxy-5:7:8:5':7':8'-hexamethyl-3:4:3':4'-tetrahydro-4:4'-dicoumarinyl-3:3'-dicarboxylate (VII) (A., R=CO<sub>2</sub>Et), m.p. 212—213° (decomp.) (diacetate, m.p. 218—219°), and 6:6'-dihydroxy-5:7:8:5':7':8'-hexamethyl-3:4:3':4'-tetrahydro-

4:4'-dicoumarinyl (VIII) (A., R=H), m.p. 290—292° (decomp.) [diacetate, m.p. 298° (decomp.)].

Similar reduction of (II) affords (IV) and (VIII). (VII) is hydrolysed (50% H<sub>2</sub>SO<sub>4</sub>, EtOH) to (VIII) which with Me<sub>2</sub>SO<sub>4</sub> in MeOH-KOH affords  $\beta\beta'$ -di-(3:5-dimethoxy-3:4:6-trimethylphenyl)adipic acid (IX), m.p. 309° (decomp.) (Me<sub>2</sub> ester, m.p. 217—218°). Hydrolysis (3% NaOH) of (VIII) gives  $\beta\beta'$ -di-(3:4:6-trimethyl-2:5-benzoquinonyl)adipic acid (X), m.p. 256—258° (decomp.) (Me<sub>2</sub> ester, m.p. 293—294°), reduced (Zn, AcOH) to (VIII). A ketone could not be obtained from (IX) and Ac<sub>2</sub>O at 300° or by pyrolysis of the Th salt. No evidence has been obtained that (I) or (II) reacts in a tautomeric form. The prep. of duroquinone (*loc. cit.*) is improved. The reaction between a fully methylated quinone and Na enolates appears to be a general method of prep. of 3-substituted 6-hydroxypolymethylcoumarins.

H. B.

**Colouring matters of violet potatoes.** I. CHMIELEWSKA (Rocz. Chem., 1935, 15, 491—505).—Negretein (I) (picrate) and tuberlin chlorides (II) are pptd. by Et<sub>2</sub>O from the HCl-MeOH extract of Negress potatoes. (I) (+8, 4, or 1 H<sub>2</sub>O) yields negretin (III) (picrate; chloride) and p-hydroxycinnamic acid when hydrolysed with 10% aq. NaOH at 0°, and (III) affords malvidin chloride, glucose, and isorhodeose with 20% HCl at the b.p. (3 min.). This suggests the appended structure for (I).

(II) yields glucose and tuberidin chloride (IV) when hydrolysed with 20% HCl, and p-OH-C<sub>6</sub>H<sub>4</sub>-CO<sub>2</sub>H is obtained by the alkaline hydrolysis of (IV), so that (IV) is a Me<sub>1</sub> ether of 3:5:6:7:8:4'-hexahydroxyflavylium chloride, and (II) is its 3-glucoside.

R. T.

**Colour and constitution of dyes derived from fluorenone.** M. K. MUKHERJEE and S. DUTT (Proc. Acad. Sci. Agra and Oudh, 1934—1935, 5, 234—239; cf. A., 1931, 627).—Fluorenone (1 mol.) with a phenol or aminophenol (2 mols.) at 180—200° in presence of dry HCl affords fluorenylidene-xanthenes. The following are prepared: 3:6-dihydroxy-, m.p. 232° (Br<sub>2</sub>-, m.p. > 300°, Bz<sub>2</sub>-, m.p. 212°, and Na<sub>2</sub> derivatives) (from resorcinol); 4:5-dihydroxy-, m.p. 169° (Br<sub>2</sub>-, m.p. > 300°, Bz<sub>2</sub>-, m.p. 141°, and Na<sub>2</sub> derivatives) (from phloroglucinol); 3:4:5:6-tetrahydroxy-, m.p. 181° (Na<sub>2</sub> derivative) (from pyrogallol); 3:6-dihydroxy-1:8-dimethyl-, m.p. > 300° (from orcinol); 3:6-tetramethyldiamino-, m.p. 111° (from m-OH-C<sub>6</sub>H<sub>4</sub>-NMe<sub>2</sub>); and 3:6-tetramethyldiamino-9-fluorenylidene-xanthen, m.p. 127° (from

$m\text{-OH}\cdot\text{C}_6\text{H}_4\cdot\text{NEt}_2$ ). The absorption max. of these dyes are analogous to those of the phthaleins, but their colour (not due to a quinonoid form) and fluorescence are less intense. J. L. D.

#### Action of sulphuric acid on diarylphthalins.

I. F. F. BLICKE and R. A. PATELSKI (J. Amer. Chem. Soc., 1936, 58, 276—278).—Contrary to Baeyer (A., 1880, 650), tetrabromophenolphthalin [prepared from phenolphthalin (I) and Br in AcOH], m.p. 209—210° (lit. 205° and 208—209°) [ $\text{Ac}_2$  derivative, m.p. 186—187° (decomp.) (lit. 165—166°)], is converted by conc.  $\text{H}_2\text{SO}_4$  into 2:5-di-(3':5'-dibromo-4'-hydroxyphenyl)-3:4-benzofuran, m.p. 240—242° (decomp.) [ $\text{Ac}_2$  derivative, m.p. 264—266° (decomp.)], which is oxidised ( $\text{KMnO}_4$ , aq. NaOH) to 3:5-dibromo-4-hydroxy-2'-(3':5'-dibromo-4'-hydroxybenzoyl)benzophenone, m.p. 298—301° (decomp.), also prepared from 4'-hydroxy-2-*p*-hydroxybenzoylbenzophenone and Br in EtOH. Reduction (Zn dust, aq. NaOH) of tetrabromophenolphthalein gives (I) (cf. *loc. cit.*). *iso*Phenolphthalein, m.p. 201—202° (from 2-*o*-hydroxybenzoylbenzoic acid, PhOH, and  $\text{ZnCl}_2$  at 90—100°), is reduced to the phthalin, m.p. 193—194° (lit. 189—190°), which is methylated ( $\text{Me}_2\text{SO}_4$ , 10% NaOH) to 2':4''-dimethoxytriphenylmethane-2-carboxylic acid, m.p. 211—212°. This and conc.  $\text{H}_2\text{SO}_4$  give 2-*o*-anisyl-5-*p*-anisyl-3:4-benzofuran (also prepared from *o*-OMe· $\text{C}_6\text{H}_4\cdot\text{MgI}$  and  $\alpha$ -*p*-anisylphthalide), which is oxidised ( $\text{Na}_2\text{Cr}_2\text{O}_7$ , AcOH) to 4'-methoxy-2-*o*-methoxybenzoylbenzophenone, m.p. 109—110° [bis-*p*-bromophenylhydrazone, m.p. 163—165° (decomp.)]. Oxidation [ $\text{K}_2\text{Fe}(\text{CN})_6$ , 10% NaOH] of 2:5-di-*p*-hydroxyphenyl-3:4-benzofuran affords 4'-hydroxy-2-*p*-hydroxybenzoylbenzophenone. H. B.

#### Synthesis of rotenone and its derivatives.

VIII. Netoric acid and toxicaric acid. A. ROBERTSON and G. L. RUSBY (J.C.S., 1936, 212—214).—*Et* derrate, m.p. 64° (by esterification of the acid), is converted by Na in PhMe at 100° into *Et* 3-hydroxy-6:4-dimethoxy- $\Delta^3$ -chromene-4-carboxylate, m.p. 109—110° [ $\text{Ac}$  derivative (I), m.p. 84°], reduced (Adams) to *Et* 3-hydroxy-6:7-dimethoxychroman-4-carboxylate (*Et* hydroxynetorate), m.p. 106°, dehydrated (boiling  $\text{Ac}_2\text{O}$ ) and hydrolysed to 6:7-dimethoxy- $\Delta^3$ -chromene-4-carboxylic acid, m.p. 210—211° (decomp.), identical with toxicaric acid. Reduction of (I) (Adams) and subsequent hydrolysis with aq. KOH affords 6:7-dimethoxychroman-4-carboxylic acid +  $\text{H}_2\text{O}$ , m.p. 90—91° (rapid heating), and anhyd., m.p. 132—133°, identical with netoric acid. When boiled with  $\text{Ac}_2\text{O}$ -NaOAc, derric acid affords a substance, m.p. 85°, probably 3-acetoxy-6:7-dimethoxy- $\Delta^3$ -chromene, hydrolysed by aq. EtOH-NaOH at 25° to a substance, decomp. 203—204°, possessing ketonic properties. J. W. B.

Preparation of 1:4-dithiens. R. H. BAKER and C. BARKENBUS (J. Amer. Chem. Soc., 1936, 58, 262—264).— $\text{COAr}\cdot\text{CH}_2\cdot\text{S}_2\text{O}_3\text{Na}$  (from  $\text{COAr}\cdot\text{CH}_2\text{Cl}$  and  $\text{Na}_2\text{S}_2\text{O}_3$ ) are hydrolysed (dry or conc. HCl in EtOH) to  $\text{COAr}\cdot\text{CH}_2\cdot\text{SH}$ , which are immediately converted into 2:5-dihydroxy-2:5-diaryl-1:4-dithians and thence (by loss of  $2\text{H}_2\text{O}$ ) into 2:5-diaryl-1:4-dithiens (59—74% yield). Condensation occurs much

less readily with  $\text{COAr}\cdot\text{CHR}\cdot\text{SH}$ ; when R is Me and Ph the yields of dithien are 11% and 0, respectively. With  $\text{COMe}\cdot\text{CH}_2\cdot\text{SH}$ , a different condensation occurs; a compound (40.8% S), b.p. 77—78°/5 mm., is produced. The following are described: *Na phenacyl* (+ $\text{H}_2\text{O}$ ), *m-nitrophenacyl*,  $\beta$ -*naphthacyl*,  $\alpha$ -*methylphenacyl* (+ $\text{H}_2\text{O}$ ), *desyl* (I), and *acetonyl* (+ $3\text{H}_2\text{O}$ ) *thiosulphates*; 2:5-diphenyl-, m.p. 115—117°, 2:5-di-*m-nitrophenyl*-, m.p. 220—222°, 2:5-di- $\beta$ -*naphthyl*-, m.p. 198—200°, and 2:5-diphenyl-3:6-dimethyl-, m.p. 135—138°, 1:4-dithiens. Hydrolysis of (I) gives a trace of a compound (9.33% S), m.p. 184.5—185°. H. B.

Catalytic transformations of heterocyclic compounds. I. Transformations of furan into pyrrole and thiophen. J. K. JURIEV (Ber., 1936, 69, [B], 440—443).—Passage of furan (I) or furfuraldehyde and  $\text{NH}_3$  over non-ignited  $\text{Al}_2\text{O}_3$  at 450° gives pyrrole (II) in 30% yield. (I) and  $\text{H}_2$  similarly afford thiophen in 31% yield. The production of (II) from  $\text{C}_2\text{H}_2$  and  $\text{NH}_3$  containing traces of  $\text{H}_2\text{O}$  in presence of  $\text{Al}_2\text{O}_3$  is probably due to intermediate formation of (I). H. W.

2:4-Dimethylpyrrole. H. FISCHER (Org. Syntheses, 1935, 15, 20—21).—The prep. from Et 2:4-dimethylpyrrole-3:5-dicarboxylate is described.

CH. ABS. (r)

Diethyl 2:4-dimethylpyrrole-3:5-dicarboxylate. H. FISCHER (Org. Syntheses, 1935, 15, 17—19).—The prep. from  $\text{CH}_2\text{Ac}\cdot\text{CO}_2\text{Et}$  is described in detail.

CH. ABS. (r)

Reactivity of bromine atoms in brominated pyridines. Preparation of some 2:6-disubstituted products of pyridine. H. J. DEN HERTOOG and J. P. WIBAUT (Rec. trav. chim., 1936, 55, 122—130).—The replacement of Hal. by  $\text{NH}_2$  in the 3 and 5 positions is described. 2:6- $\text{C}_5\text{H}_3\text{NBr}_2$  (cf. A., 1932, 522) when heated with NaOH in EtOH yields 6-bromo-2-ethoxypyridine (I), b.p. 218—219°, which when heated with NaOEt in EtOH in a sealed tube gives 2:6-diethoxypyridine, m.p. 21.5°. 6:2- $\text{C}_5\text{H}_3\text{NBr}\cdot\text{NH}_2$  (*loc. cit.*) similarly yields 2-amino-6-ethoxypyridine, b.p. 238° (*picrate*, m.p. 216—222°; *Ac* derivative, m.p. 136—137°), and with  $\text{NaNO}_2$  and  $\text{H}_2\text{SO}_4$  gives 6-bromo-2-hydroxypyridine, m.p. 123° (*Na* salt). 2:6- $\text{C}_5\text{H}_3\text{NBr}_2$  with  $\text{C}_5\text{H}_{11}\text{N}$  in  $\text{C}_5\text{H}_5\text{N}$  at 160° yields 6-bromo-2-piperidinopyridine, b.p. 120—125°/0.1 mm., which with  $\text{C}_5\text{H}_{11}\text{N}$  in  $\text{C}_5\text{H}_5\text{N}$  at 180° gives 2:6-dipiperidinopyridine, m.p. 39—40°. Similarly 6:2- $\text{C}_5\text{H}_3\text{NBr}\cdot\text{NH}_2$  and (I) give, respectively, 2-amino-6-piperidino-, b.p. 202°/30 mm., m.p. 38—39° (*Ac* derivative, m.p. 116—117°), and 6-piperidino-2-ethoxy-pyridine, b.p. 170°/22 mm. (*picrate*, two forms, m.p. 122° and 142°). 2- $\text{C}_6\text{H}_4\text{N}\cdot\text{Hal}$  does not react with Mg. The antiseptic properties of these compounds are described. F. R. G.

1-Methyl-2-pyridone. E. A. PRILL and S. M. McELVAIN (Org. Syntheses, 1935, 15, 41—44).—( $\text{C}_5\text{H}_5\text{NMe}$ ) $\text{MeSO}_4$  (from  $\text{C}_5\text{H}_5\text{N}$  and  $\text{Me}_2\text{SO}_4$ ) is oxidised with alkaline  $\text{K}_3\text{Fe}(\text{CN})_6$ . CH. ABS. (r)

Phenylhydrazone of *N*-phenylaminochelidamic ester. E. KOENIGS and H. GURLT (Ber., 1936, 69, [B], 358).— $\text{Et}_2$  acetonedioxalate and  $\text{NHPh}\cdot\text{NH}_2$  in boiling EtOH afford the phenyl-

hydrazone of *Et*, 1-anilino-4-keto-1 : 4-dihydropyridine-2 : 6-dicarboxylate, m.p. 194°, which is not reduced to the corresponding  $\text{NH}_2$ -compound by  $\text{SnCl}_2$  and  $\text{HCl}$ . H. W.

**Indole compounds.** J. GNEZDA (Rad., 244, 13—15; Chem. Zentr., 1935, i, 3574).—Several colour reactions are described. H. N. R.

**Halogenated ketones. IIIa. Pyrrole. IVa. Skatole.** G. SANNA (Rend. Semin. Fac. Sci. Univ. Cagliari, 1934, 4, 59—61; Chem. Zentr., 1935, ii, 219; cf. A., 1933, 1169).—IIIa. Condensation of  $\text{CHMeBr}\cdot\text{COCl}$  with  $\text{Mg}$ -pyrrole affords 2- $\alpha$ -bromopropionylpyrrole, m.p. 106°, which gives a pyrrole-black with alkali.

IVa [with F. ATHENE]. Condensation of  $\text{Mg}$ -skatole with  $\text{CHCl}_2\cdot\text{COCl}$  or  $\text{CCl}_3\cdot\text{COCl}$  yields 1-di- or 1-tri-chloroacetyl-3-methylindole, which cannot readily be isolated as they break down into  $\text{CO}_2$ ,  $\text{CHCl}_3$ , and skatole; 2-substituted compounds are not obtained. H. N. R.

**Ring-closures of derivatives of 2-aminostyrene.** T. W. J. TAYLOR and (Miss) P. M. HOBSON (J.C.S., 1936, 181—184).—2-Acetamidostyrene (I) with  $\text{POCl}_3$  gives quinaldine, whilst adipodi-2-vinylanilide, m.p. 202°, obtained from 2-aminostyrene and adipyl chloride, similarly forms  $\alpha$ -di-(2-quinolyl)butane, m.p. 98°, and 2-n-hexamidostyrene, m.p. 61°, affords 2-n-amylquinoline (picrate, m.p. 104—105°; lit., 111—112°). (I) and  $\text{Br}$  yield (I) dibromide, m.p. 125°, which with  $\text{KOH}$  gives indole. *cis*-2-Nitrostilbene, obtained from 2-nitro- $\alpha$ -phenylcinnamic acid and  $\text{Cu}$  chromate, is reduced to the  $\text{NH}_2$ -compound, of which the *Ac* derivative, m.p. 112—113°, with  $\text{POCl}_3$ , yields 3-benzylidene-2-methylindolenine, also obtained from the corresponding *trans*-compound. Diazotisation of the *cis*- $\text{NH}_2$ -compound gives phenanthrene, but none is obtained from the *trans*-compound. The results indicate the structure (II) and (III) for *cis*- and *trans*-, (III) being the compound previously known.

Diazotisation of 4-aminophenylethyl alcohol affords  $\beta$ -4-bromophenylethyl alcohol, m.p. 36—38° (phenylurethane, m.p. 126°). F. R. S.

**Relation between chemical constitution and anaesthetic activity of 2-alkoxyquinoline derivatives.** H. WOJAHN (Arch. Pharm., 1936, 274, 83—106).—2-Chloro-4-quinoloyl chloride (I) (in  $\text{C}_6\text{H}_6$ ) and  $\text{NH}_2\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{NHAc}$  (in  $\text{H}_2\text{O}$ ) give 2-chloroquinoline-4-carboxyl- $\beta$ -acetamidoethylamide, m.p. 245°, converted by  $\text{EtOH}\cdot\text{NaOEt}$  into the 2-ethoxy-derivative, m.p. 209°. 2-Ethoxy-4-quinoloyl chloride (A., 1931, 1167) and  $\text{NH}_2\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{NH}\cdot\text{COEt}$  similarly afford 2-ethoxyquinoline-4-carboxyl- $\beta$ -propionamidoethylamide, m.p. 204°; with  $\text{C}_2\text{H}_5(\text{NH}_2)_2$ ,  $\text{NN}'$ -di-2-ethoxy-4-quinolylethylenediamine, m.p. 280°, results. (I) (in  $\text{PhMe}$ ) and conc. aq.  $\text{NH}_3$  give 2-chloroquinoline-4-carboxylamide (II), m.p. 239—240°, converted by  $\text{NaOAlk}$  in  $\text{AlkOH}$  into 2-ethoxy-, m.p. 200—201°, and 2-butoxy-, m.p. 160°, -quinoline-4-carboxylamides.

2-Butoxyquinoline-4-carboxyldiethylamide\* (from the 2-Cl-derivative and  $\text{NaOBU}$ ) has b.p. 270°/20 mm., m.p. 62°. The above amides are converted by  $\text{NaOBr}$  into 2-chloro-4-amino-, m.p. 188° (hydrochloride, m.p. 250°), and 4-amino-2-ethoxy-, m.p. 128°, and -2-butoxy-, m.p. 85°, -quinoline, respectively. (II) is dehydrated by  $\text{SOCl}_2$  to 2-chloro-4-cyanoquinoline, m.p. 156°, which with  $\text{NaOAlk}$  gives 4-cyano-2-ethoxy-, m.p. 86°, and -2-butoxy-, b.p. 198°/18 mm., m.p. 31°, -quinoline, reduced ( $\text{H}_2$ ,  $\text{Pd}\cdot\text{BaSO}_4$ ,  $\text{AcOH}$ ) to 2-ethoxy-\* (III), b.p. 205°/20 mm., m.p. 53° [di-hydrochloride, m.p. 230° (decomp.)], and 2-butoxy-\* (IV), b.p. 225°/17 mm., m.p. 51° (dihydrochloride, m.p. >230°), -4-aminomethylquinoline, respectively. Catalytic reduction of the Schiff base from (III) and the appropriate  $\text{RCHO}$  or  $\text{CORR}'$  affords 2-ethoxy-4-propyl-, m.p. 207°, -4-benzyl-, m.p. 131°, and -4- $\beta$ -phenylethyl-, m.p. 250°, -aminomethylquinoline hydrochlorides, and 2-ethoxy-4-isobutyl-, m.p. 115°, and -4-phenylisopropyl-, m.p. 110°, -aminomethylquinoline dihydrochlorides. (IV) similarly gives 2-butoxy-4-propyl-, m.p. 213°, -4-benzyl-, m.p. 177°, -4- $\beta$ -phenylethyl-, m.p. 134°, and -4-phenylisopropyl-, m.p. 156°, -aminomethylquinoline hydrochlorides, and 2-butoxy-4-isobutyl-, m.p. 120°, and -4-phenylisopropyl-, m.p. 115°, -aminomethylquinoline dihydrochlorides. 2-Ethoxy-4- $\gamma$ -methylamino- (trihydrochloride, m.p. 121°), and -4- $\gamma$ -diethylamino- (trihydrochloride, m.p. 71°), - $\beta\beta$ -dimethylpropylaminomethylquinolines are similarly prepared from (III) and  $\text{NHMe}\cdot\text{CH}_2\cdot\text{CMe}_2\cdot\text{CHO}$  and  $\text{NEt}_2\cdot\text{CH}_2\cdot\text{CMe}_2\cdot\text{CHO}$ , respectively. (III) and  $\text{CH}_2\text{Cl}\cdot\text{CH}_2\cdot\text{NEt}_2\cdot\text{HCl}$  at 150—160° give 2-ethoxy-4- $\beta$ -diethylaminoethylaminomethylquinoline (trihydrochloride, m.p. 128°). 4-Cyano-2-ethoxyquinoline (V) and  $\text{MgMeI}$  ( $\pm 2$  mols.) in  $\text{PhOMe}$  afford 2-ethoxy-4-quinolyl *Me* ketone, m.p. 57° (hydrochloride, m.p. 108°; picrate, m.p. 101°), converted by  $\text{Br}$  in cold  $\text{CS}_2$  into the  $\text{CH}_2\text{Br}$  ketone hydrobromide, m.p. 80°, which with  $\text{EtOH}\cdot\text{NHET}_2$  affords 2-ethoxy-4-quinolyl diethylaminomethyl ketone, b.p. 175°/18 mm. (dihydrochloride, m.p. 65°), reduced ( $\text{H}_2$ ,  $\text{Pd}\cdot\text{BaSO}_4$ ,  $\text{EtOH}$ ) to 2-ethoxy-4- $\beta$ -diethylamino- $\alpha$ -hydroxyethylquinoline (hydrochloride, m.p. 157°). (V) and  $\text{MgEtI}$  similarly give 2-ethoxy-4-quinolyl *Et* ketone, b.p. 198—203°/20 mm. (hydrochloride, m.p. 90°; picrate, m.p. 158°), and thence the  $\alpha$ -bromoethyl (hydrobromide, m.p. 114°) and  $\alpha$ -diethylaminoethyl, b.p. 175—180°/18 mm. (dihydrochloride, m.p. 89°), ketones. 2-Ethoxy-4-quinolyl *Pr*, b.p. 190—200°/20 mm. (picrate, m.p. 150°),  $\alpha$ -bromopropyl (hydrobromide, m.p. 123°), and  $\alpha$ -diethylaminopropyl, b.p. 180°/20 mm. (dihydrochloride, m.p. 100°), ketones are similarly prepared. These  $\text{NEt}_2$ -ketones are vaso-constrictors. Of the various amines prepared, only those marked \* possess anaesthetic activity. These and previous results (*loc. cit.*) show that the 2-alkoxyquinolyl is the active group; the activity of percaïne [2-butoxyquinoline-4-carboxyl- $\beta$ -diethylaminoethylamide] is not due to the presence of the  $\cdot\text{N}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{N}\cdot$  grouping. The  $\text{CO}_2\text{H}$  (*cf. loc. cit.*) is not essential.

H. B.

$\alpha\beta$ -Diarylethylamines and their transformation into tetrahydroisoquinolines. I. B. REICHERT and W. HOFFMANN (Arch. Pharm., 1936,

274, 153—173).— $\alpha$ -Nitrostilbenes are hydrogenated (Pd-black) in  $C_6H_5N$  at 40—60° to deoxybenzoinoximes, which with 3% Na-Hg in EtOH-AcOH give the  $\alpha$ -diarylethylamines. These bases with hot aq.  $CH_2O$  give Schiff's bases, which are cyclised in excellent yield by hot 10% HCl to 3-aryltetrahydroisoquinolines if, but only if, Ar has OR in the *p*-position. A C-C chain could be attached to the *sec*.-N thus formed, but ring-closure with the 3-aryl nucleus could not be effected. The following are prepared by the above methods, the direction of ring-closure being proved by the reactions described.  $\beta$ -Nitro-3-methoxy- $\alpha$ - $\beta$ -diphenylethylene (from *m*-OMe- $C_6H_4$ ·CHO,  $CH_2Ph$ ·NO<sub>2</sub>, and a little  $NHMe_2$  kept in EtOH at room temp. for 4 days), m.p. 78°. Deoxybenzoinoxime, m.p. 94°; 3:4-methylenedioxy-, m.p. 138°, 3-methoxy-, m.p. 80°, 3:4-, m.p. 108°, and 2:4-dimethoxy-deoxybenzoinoxime, m.p. 91°.  $\alpha$ -Phenyl- $\beta$ -3:4-methylenedioxy-, m.p. 37—38°, b.p. 222—223°/17 mm. [acetate, m.p. 152—153°; hydrochloride, m.p. 258—259° (decomp.); Bz derivative, m.p. 180°], -4- (I), b.p. 202—203°/12 mm. (acetate, m.p. 135°; hydrochloride, m.p. 208—209°), and -3-methoxy-, b.p. 192°/11 mm. (hydrochloride, m.p. 205—207°), -3:4-, m.p. 67°, b.p. 233°/16 mm. (H oxalate, m.p. 176°; Bz derivative, m.p. 178°), and -2:4-dimethoxy-, b.p. 230—231°/18 mm. (hydrochloride, m.p. 214°; Bz derivative, m.p. 183—184°), and -4-hydroxyphenylethylamine [from (I) and 38% HCl at 150°], m.p. 159° (hydrochloride, m.p. 252° after sintering);  $\alpha$ -di-3:4-methylenedioxyphenylethylamine hydrochloride, m.p. 254° (lit. 245°). 6:7-Methylenedioxy (II), m.p. 82—83° [hydrochloride, m.p. 245—246° (decomp.); NO-derivative, m.p. 125°], 6:7-dimethoxy-, m.p. 96° [hydrochloride, m.p. 258° (decomp.); NO-derivative, m.p. 100°], and 6-methoxy-3-phenyl-1:2:3:4-tetrahydroisoquinoline (III), m.p. 72—73° (hydrochloride, m.p. about 263°); 6:7-methylenedioxy-3-3':4'-methylenedioxyphenyl-1:2:3:4-tetrahydroisoquinoline (IV), m.p. 124—125° (hydrochloride, m.p. 250—251°; NO-derivative, m.p. 149°). (II) and hot aq.  $KMnO_4$  afford 6:7-methylenedioxy-3-phenylisoquinoline (23% yield), m.p. 128° [hydrochloride, m.p. about 270°; methiodide, m.p. 239° (decomp.) after sintering], BzOH, and a small amount of a nitrogenous acid, m.p. 276°; (IV) and  $KMnO_4$  give similarly a small amount of 6:7-methylenedioxy-3-3':4'-methylenedioxyphenylisoquinoline, m.p. 210—211°. (II) and MeI yield 6:7-methylenedioxy-3-phenyl-2-methyl-1:2:3:4-tetrahydroisoquinoline methiodide, m.p. 268°, which (a) with Na-Hg in hot  $H_2O$  gives 4:5-methylenedioxy-2- $\beta$ -phenylethylbenzyl-dimethylamine (V), an oil (oxalate, m.p. 173°), the methiodide, m.p. 211°, of which with Na-Hg affords 4:5-methylenedioxy-2- $\beta$ -phenylethyltoluene, m.p. 49°, and (b) with hot conc. KOH gives 4:5-methylenedioxy-2-dimethylaminomethylstilbene, an oil (oxalate, m.p. 221—222°), hydrogenated (Pd-C) in warm  $H_2O$  to (V) and oxidised by hot aq.  $KMnO_4$  to BzOH and hydrastic acid. 6-Methoxy-3-phenyl-2-methyl-1:2:3:4-tetrahydroisoquinoline methiodide [from (III) and MeI], m.p. 255—258°, with hot conc. KOH gives 5-methoxy-2-dimethylaminomethylstilbene (oxalate, m.p. 181—182°), oxidised by  $KMnO_4$  to  $NHMe_2$ , BzOH, and 4-methoxyphthalic acid (anhydride, m.p. 92°).

(II) and (IV) with excess of  $CH_2Br$ · $CH_2$ ·OH give poor yields of 6:7-methylenedioxy-3-phenyl-, m.p. 92—93° (hydrochloride, m.p. 220—222°), and -3-3':4'-methylenedioxy-2- $\beta$ -hydroxyethyl-1:2:3:4-tetrahydroisoquinoline, m.p. 49° (hydrochloride, m.p. 258°); attempts to dehydrate these OH-bases by  $NaOEt$ ,  $P_2O_5$  in PhMe, and long boiling in tetralin were unsuccessful;  $SOCl_2$  in  $CHCl_3$  led to mixtures. R. S. C.

**Synthesis of succinic acid-isoquinoliniumbetaines.** O. LUTZ and A. KRAUHLIS (Ber., 1936, 69, [B], 419—422).—isoQuinoline (I) and maleic acid (II) in abs.  $Et_2O$  at room temp. afford isoquinolinium *H* maleate, m.p. 103°, which passes when heated into succinic acid-isoquinoliniumbetaine (III),  $C_9H_7N$ — $\begin{matrix} \text{CH} \cdot \text{CO}_2\text{H} \\ \text{O} \cdot \text{CO} \cdot \text{CH}_2 \end{matrix}$ , m.p. (anhyd.) 151—152°, m.p. (+1H<sub>2</sub>O) 149—150°, better obtained by keeping (I) and (II) in MeOH or  $H_2O$  for some time at room temp. or by heating them in  $H_2O$  at 50—60°. (III) is also obtained similarly from (I) and fumaric acid and also appears to be produced from *l*-bromosuccinic acid. H. W.

**Carbon double linkings and nitrogen-carbon linkings. XIII. Degradation of quaternary ammonium compounds by catalytic hydrogenation.** H. EMDE and H. KULL (Arch. Pharm., 1936, 274, 173—184; cf. A., 1934, 515).—Many quaternary  $NH_4$  salts are hydrogenated to *tert*.-bases but the reaction differs in ease and often in course from the Na-Hg reduction.  $CH_2$ · $CH$ · $CH_2$ · $NMe_3I$  with  $H_2$ -Pt (not Pd) in AcOH or  $H_2O$  gives  $NMe_3$  (63%), a little  $C_3H_6$ , more  $C_3H_8$ , and much  $NMe_3Pr^+I$  (unaffected by hydrogenation).  $CHPh$ · $CH$ · $NMe_3Cl$  with  $H_2$ -Pt or -Pd gives  $PhPr^+$  (70%),  $NMe_3$ , and  $Ph$ · $[CH_2]_3$ · $NMe_3Cl$  (not degraded by hydrogenation, but slowly giving the cyclohexyl derivative).  $CH_2Ph$ · $NPhMe_2Cl$  with  $H_2$ -Pd gives PhMe and  $NPhMe_2$ , with  $H_2$ -Pt methylcyclohexane (I) and cyclohexyldimethylamine (platini-, m.p. 158°, and auri-chloride, m.p. 105°).  $CH_2$ · $CH$ · $CH_2$ · $NMeI$ · $CH_2Ph$ ,  $CH_2Ph$ · $NMe_3Cl$ , and  $CH_2Ph$ · $NMe_3I$  are unaffected by  $H_2$ -Pd, but the two last salts with  $H_2$ -Pt give  $NMe_3$  (96%) and PhMe [or by longer hydrogenation (I)].  $(CH_2Ph)_2NMe_2I$  with  $H_2$ -Pd in 50% AcOH or  $(CH_2Ph)_2NMe_2Cl$  with  $H_2$ -Pt in  $H_2O$  gives PhMe and  $NMe_3$ · $CH_2Ph$  very slowly.  $NPhMe_3Cl$  in AcOH with  $H_2$ -Pt (not Pd) gives slowly  $NMe_3$  and  $C_6H_6$  and then cyclohexane. 1-Methylpiperidine methiodide and methochloride, hygroscopic, cannot be hydrogenated. 1-Methyltetrahydroquinoline methiodide (methoaurichloride, m.p. 184°; methosulphate, m.p. 198°) with  $H_2$ -Pt (not Pd) in  $H_2O$  (not AcOH) gives  $Ph$ · $[CH_2]_3$ · $NMe_2$ , and 2-methyltetrahydroisoquinoline methiodide, m.p. 189°, or methochloride (methoaurichloride, m.p. 187°) yields similarly  $\beta$ -o-tolyethyl-dimethylamine, b.p. 223—224° [hydrochloride, m.p. 221°; platinichloride, m.p. 168° (decomp.); picrate, m.p. 126—127°; methoaurichloride, m.p. 156°, and -picrate, m.p. 152°]. Hydrogenation of  $o$ - $CH_2$ · $CH$ · $C_6H_4$ · $CH_2$ · $NMe_2$  affords *o*-ethylbenzyl-dimethylamine (auri-, m.p. 148°, and platini-chloride, m.p. 166—167°; picrate, m.p. 133—5°; methiodide, m.p. 226°; methoaurichloride, m.p. 187°). R. S. C.

**2:8-Dialkoxy-10-alkylacridinium derivatives** with various kinds of amino-group in the 5-position. X. Synthesis of 2:8-dialkoxy-5-*p*-aminoanilino-10-alkylacridinium derivatives and (2':8'-dialkoxy-10'-alkyl-10'-substituted-acridyl)-5:5'-*p*-phenylenediamino-2:8-dialkoxy-10-alkylacridinium derivatives. XI. Synthesis of 2:8-dialkoxy-5-piperazino-10-alkylacridinium and (2':8'-dialkoxy-10'-alkyl-10'-substituted-acridyl)-5:5'-piperazino-2:8-dialkoxy-10-alkylacridinium derivatives. K. ISHIIHARA (J. Chem. Soc. Japan, 1935, 56, 289—313, 457—485; cf. this vol., 343).—X. The following reactions are described for the 2:8-(OMe)<sub>2</sub>- and -(OEt)<sub>2</sub>-compounds, with OH and Cl as 10-acridinium anions: 5-chloro-2:8-dialkoxy-10-alkylacridinium chloride (I) and *p*-C<sub>6</sub>H<sub>4</sub>(NH<sub>2</sub>)<sub>2</sub> give the hydrochloride (II) of the 5-*p*-aminoanilino-derivative (III) and the (acridinium) dialkoxide of NN'-bis-(2:8-dialkoxy-5-acridyl)-*p*-phenylenediamine, also obtained from (II) and (III).

XI. The (I) and piperazine (as above) give the hydrohalide (I as well as Cl) (IV) of the corresponding 5-piperazino-derivative and the (acridinium) dialkoxide (V) of NN'-bis-(2:8-dialkoxy-5-acridyl)-piperazine. (IV), with KOH·CHCl<sub>3</sub>, gives (V) and with H<sub>2</sub>O gives the 10-alkyl-5-acridone (VI), also formed by similarly treating either (V) or the (piperazinium or acridinium) dioxalate or the (acridinium) iodide or (piperazinium) oxalate corresponding with (IV). CH. ABS. (r)

**Sulphonation of acridone, and certain transformations of acridone-3-sulphonic acid.** M. POLACZEK (Rocz. Chem., 1935, 15, 565—577).—Acridone and conc. H<sub>2</sub>SO<sub>4</sub> at 100° yield acridone-3-sulphonic acid (I) [Ba and Pb salts; chloride; amide; Et ester, m.p. 232—233° (decomp.)], also synthesised by heating *o*-C<sub>6</sub>H<sub>4</sub>Cl·CO<sub>2</sub>K and K sulphanilate in H<sub>2</sub>O in presence of Cu (115—120°; 6 hr.), and condensing the K 4'-sulphodiphenylamine-2-carboxylate obtained in presence of POCl<sub>3</sub> at 115° (30 min.). When fused with KOH (I) yields 3-hydroxyacridone, m.p. 330—370° (benzoate, m.p. 285—287°), identical with the product obtained from 4'-ethoxydiphenylamine-2-carboxylic acid and H<sub>2</sub>SO<sub>4</sub> (100°; 15 min.). (I) in POCl<sub>3</sub> and NPhMe<sub>2</sub> (120°; 1 hr.) yield 3-*p*-dimethylaminobenzenesulphonyl-5-*p*-dimethylaminophenylacridone, m.p. 264—265°. (I) and 80% oleum at 100° afford acridone-3:7-disulphonic acid (Ba and Pb salts), also prepared from 2-chloro-5-sulphobenzoic acid and sulphanilic acid in presence of Cu and K<sub>2</sub>CO<sub>3</sub> (115—120°; 8 hr.), followed by condensation of the product with H<sub>2</sub>SO<sub>4</sub> at 100° R. T.

**Acridine compounds and their antimalarial action.** I. O. J. MAGIDSON and A. M. GRIGOROVSKI (Ber., 1936, 69, [B], 396—412).—Compounds of the type 8-chloro-5-diethylamino-R-amino-3-methoxyacridine have a very powerful antimalarial action which attains a max. when R=[CH<sub>2</sub>]<sub>4</sub>. Introduction of OH into the side-chain diminishes the therapeutic action if Cl is present, but increases it in the presence of NO<sub>2</sub>. Compounds without a substituent at 7 or 8 are therapeutically inactive. Increase in the size of 3-OAlk diminishes the therapeutic activity,

which vanishes if a second OMe is present. Protracted treatment of compounds of the above type with boiling H<sub>2</sub>O causes elimination of the 5-N-chain and production of acridones. With conc. HCl at 120—125° the 5-aminoacridone is formed, demethylation also occurring to some extent. The condensation of 5-chloroacridines with primary amines occurs only in presence of PhOH, since the 9-OPh-compounds readily react with amines under similar conditions, they appear to be intermediates.

α-Diethylaminobutan-γ-one is converted into the oxime, b.p. 141—142°/15 mm., which is reduced by Na powder in BuOH to γ-amino-α-diethylaminobutane, b.p. 72—74°/12 mm. NH<sub>2</sub>·[CH<sub>2</sub>]<sub>2</sub>·NEt<sub>2</sub>, b.p. 145—149° atm. pressure, is obtained from *o*-C<sub>6</sub>H<sub>4</sub>(CO)<sub>2</sub>N·[CH<sub>2</sub>]<sub>2</sub>·Br and NEt<sub>2</sub> in boiling xylene followed by hydrolysis with 12*N*-HCl, and NH<sub>2</sub>·[CH<sub>2</sub>]<sub>3</sub>·NEt<sub>2</sub>, b.p. 55—58°/12 mm., is derived from *o*-C<sub>6</sub>H<sub>4</sub>(CO)<sub>2</sub>N·[CH<sub>2</sub>]<sub>3</sub>·Cl and NEt<sub>2</sub> or from *o*-C<sub>6</sub>H<sub>4</sub>(CO)<sub>2</sub>NK and NEt<sub>2</sub>·[CH<sub>2</sub>]<sub>3</sub>·Cl. ε-Diethylaminomethylamine, b.p. 205—208°, is obtained from NHBz·[CH<sub>2</sub>]<sub>5</sub>·Cl and NEt<sub>2</sub> at 100—120°, followed by hydrolysis with conc. HCl at 125°. NHBz·[CH<sub>2</sub>]<sub>5</sub>·Cl, PBr<sub>3</sub>, and Br give α-chloro-ε-bromopentane, b.p. 210—212°, transformed by the successive action of NaCN in MeOH and NEt<sub>2</sub> into ε-diethylaminohexonitrile, b.p. 92—97°/3.5 mm., reduced by powdered Na in abs. EtOH to α-amino-8-diethylaminohexane, b.p. 216—218° (aurichloride, m.p. 120—122°). *o*-C<sub>6</sub>H<sub>4</sub>Cl·CO<sub>2</sub>H, K<sub>2</sub>CO<sub>3</sub>, and *p*-OMe·C<sub>6</sub>H<sub>4</sub>·NH<sub>2</sub> in boiling amyl alcohol containing a trace of Cu powder give *N*-*p*-anisylanthranilic acid, m.p. 183—184°, transformed by boiling POCl<sub>3</sub> into 5-chloro-3-methoxyacridine, m.p. 152—153°. Nitration of *o*-C<sub>6</sub>H<sub>4</sub>Cl·CO<sub>2</sub>H and condensation of the product with *p*-OMe·C<sub>6</sub>H<sub>4</sub>·NH<sub>2</sub> affords 5-nitro-*N*-*p*-anisylanthranilic acid, m.p. 216—220°, transformed into 5-chloro-8-nitro-3-methoxyacridine, m.p. 220—221°. Aminoveratrole and 2:4-C<sub>6</sub>H<sub>3</sub>Cl<sub>2</sub>·CO<sub>2</sub>H afford 4-chloro-*N*-3':4'-dimethoxyphenylanthranilic acid, m.p. 190—191°, whence 5:7-dichloro-(?)2:3-dimethoxyacridine, m.p. 202—203°. Gradual addition of NH<sub>2</sub>·[CH<sub>2</sub>]<sub>2</sub>·NEt<sub>2</sub> to a mixture of 5-chloro-3-ethoxyacridine and PhOH at 70—80° affords 5-β-diethylaminoethylamino-3-ethoxyacridine, m.p. 242—244°. The following acridines are obtained by similar methods: 7-nitro-5-β-diethylaminoethylamino-3-ethoxy-, m.p. 246—252°; 8-nitro-5-β-diethylaminoethyl-3-ethoxy-, m.p. 172—175° [dihydrochloride, m.p. 243—246° (decomp.)]; 7-nitro-5-γ-diethylaminopropylamino-3-ethoxy- [dihydrochloride (+H<sub>2</sub>O), m.p. 226—228°]; 7-chloro-5-γ-diethylaminopropylamino-3-methoxy- [dihydrochloride (+3H<sub>2</sub>O), m.p. 249—250°]; 8-nitro-5-γ-diethylamino-β-hydroxypropylamino-3-methoxy-, m.p. 124° (dihydrochloride, m.p. 213—214°); 7-chloro-5-β-hydroxy-γ-diethylaminopropylamino-3-methoxy-, m.p. 105—107° (dihydrochloride, m.p. 237—239°); 7-chloro-5-8-diethylaminobutylamino-3-methoxy-, m.p. 76—78° (dihydrochloride, m.p. 246—248°); 7-chloro-5-8-diethylamino-α-methylbutylamino-3-methoxy-, m.p. 86—88° (dihydrochloride, m.p. 246—248°); 5-γ-diethylaminopropylamino-3-methoxy- (dihydrochloride, m.p. 240—241°); 8-nitro-5-γ-diethylaminopropylamino-3-methoxy-, m.p. 122—123.5° (dihydrochloride, m.p. 229—230°); 7-chloro-5-γ-diethylaminopropyl-

amino-(?)2:3-dimethoxy- [dihydrochloride (+2H<sub>2</sub>O), m.p. 227—228°]; 7-chloro-5-di-( $\gamma$ -diethylaminopropyl)-amino-3-methoxy- (very unstable hydrochloride); 7-chloro-5-8-diethylamino- $\alpha$ -methylbutylamino-(?)2:3-dimethoxy- [dihydrochloride (+2H<sub>2</sub>O), m.p. 217—218°]; 7-chloro-5- $\gamma$ -diethylaminopropylamino-3-ethoxy- [dihydrochloride (+1H<sub>2</sub>O), m.p. 246—247°]; 7-chloro-5-8-diethylaminobutylamino-3-ethoxy- [dihydrochloride (+2H<sub>2</sub>O), m.p. 254—255.5°]; 7-chloro-5- $\gamma$ -diethylaminopropylamino-3-methyl- [dihydrochloride (+2H<sub>2</sub>O), m.p. 239—241°]; 7-chloro-5- $\epsilon$ -diethylaminoamylamino-3-methoxy- [dihydrochloride (+H<sub>2</sub>O), m.p. 266—268°]; 7-chloro-5- $\beta$ -diethylaminoethylamino-3-methoxy- (dihydrochloride, m.p. 258—259°); 7-chloro-5- $\gamma$ -diethylamino- $\alpha$ -diethylamino- $\alpha$ -methylpropylamino-3-methoxy- [dihydrochloride (+1H<sub>2</sub>O), m.p. 253—254°]; 7-chloro-5- $\epsilon$ -diethylaminoheptylamino-3-methoxy- (dihydrochloride, m.p. 232—235°). H. W.

Manufacture of acridine derivatives.—See B., 1936, 299.

Water-soluble salt of 3:6-diamino-10-methyl-acridinium.—See B., 1936, 220.

Optical activity dependent on co-ordinated bivalent ruthenium. F. H. BURSTALL (J.C.S., 1936, 173—175).—2:2'-Dipyridyl with RuCl<sub>3</sub> at 250° gives tris-2:2'-dipyridylruthenous chloride, from which the corresponding base, tris-2:2'-dipyridylruthenous bromide octahydrate, [Ru dipy<sub>3</sub>](OH)<sub>2</sub>·8H<sub>2</sub>O, and the bromide, iodide, perchlorate, nitrate, carbonate, and tartrate have been prepared. All these salts form hexahydrates, the carbonate also forming a decahydrate; they are more stable than the corresponding Fe<sup>++</sup> and Ni<sup>++</sup> salts. Resolution of the *d*- and *l*-tartrates gave *d*-, [ $\alpha$ ]<sub>D</sub><sup>25</sup> +860°, [*M*] +7205°, and *l*-tris-2:2'-dipyridylruthenous bromide hexahydrate, [ $\alpha$ ]<sub>D</sub><sup>25</sup> -815°, [*M*] -6828°, respectively. L. J. J.

Preparation of NN'-disubstituted barbituric and thiobarbituric acids. N. V. KOSCHKIN (J. Gen. Chem. Russ., 1935, 5, 1460—1467).—Disubstituted barbituric acids cannot be obtained from sodiomalonic ester and substituted carbamides and thiocarbamides, under various temp. conditions. NN'-Diphenylbarbituric acid, m.p. 238.5—239°, was obtained by heating a mixture of CO(NHPh)<sub>2</sub> (I) and CH<sub>2</sub>(CO<sub>2</sub>H)<sub>2</sub> with AcCl in dry CHCl<sub>3</sub> at the b.p. for 4 hr.; NN'-di-*o*-tolylbarbituric acid, m.p. 176.5—177°, and NN'-di-*o*-tolyl-, m.p. 216.5—217°, NN'-di- $\alpha$ -, m.p. 250—250.5° (decomp.), and NN'-di- $\beta$ -naphthylthiobarbituric acid, m.p. 247.5—248°, were obtained analogously. (I) and CH<sub>2</sub>(CO<sub>2</sub>Et)<sub>2</sub> in xylene at the b.p. yield CH<sub>2</sub>(CO·NHPh)<sub>2</sub>. R. T.

[Glyoxalinecarboxylic esters.] W. JOHN (Ber., 1936, 69, [B], 484; cf. this vol., 211).—The ability of glyoxalinecarboxylic esters to lose CO<sub>2</sub> when heated is also shown by certain indazole- and pyrazolecarboxylic esters. H. W.

Synthesis of 1-phenyl-4- $\beta$ -hydroxyethylpiperazine. C. B. KREMER (J. Amer. Chem. Soc., 1936, 58, 379).—N(CH<sub>2</sub>·CH<sub>2</sub>·OH)<sub>3</sub>, NH<sub>2</sub>Ph, and conc. H<sub>2</sub>SO<sub>4</sub> give 1-phenyl-4- $\beta$ -hydroxyethylpiperazine, m.p. 84° (corr.) (lit. 83° and 91°). H. B.

Pyrimidines. CXLIX. Synthesis of aryl-substituted dihydrouacils and their conversion into uracils. T. B. JOHNSON and J. E. LIVAK (J. Amer. Chem. Soc., 1936, 58, 299—303).—Hydrobenzamide and CH<sub>2</sub>(CO<sub>2</sub>H)<sub>2</sub> in cold EtOH give  $\beta$ -amino- $\beta$ -phenylethane- $\alpha\alpha$ -dicarboxylic acid, m.p. 153°; in the hot,  $\beta$ -amino- $\beta$ -phenylpropionic acid (I) results (cf. Rodionov *et al.*, A., 1929, 557; 1933, 1307). (I) is also prepared from CH<sub>2</sub>(CO<sub>2</sub>H)<sub>2</sub>, PhCHO, and EtOH·NH<sub>3</sub> or -NH<sub>4</sub>OAc.  $\beta$ -Amino- $\beta$ -anisylpropionic acid (II), m.p. 232° (decomp.), is similarly prepared using anishydramide. (I) and (II) with ArNCO give the  $\beta$ -arylcarbamido-acids, which are converted (usually by Ac<sub>2</sub>O) into 4-phenyl-1-aryl- (A) and 4-anisyl-1-aryl- (B) 4:5-dihydrouacils, respectively; ArNCS leads to the 2-thion analogues. Bromination of (A) in AcOH at 75—105° gives the 5-Br-derivative when aryl=Ph or *o*-tolyl; when aryl =  $\beta$ -C<sub>10</sub>H<sub>7</sub> or *p*-NO<sub>2</sub>-C<sub>6</sub>H<sub>4</sub>, bromination is retarded or inhibited. With (B), introduction of Br into the 3 position of the anisyl group first occurs; the resulting compounds then behave as (A). The following are described:  $\beta$ -carbamido-, m.p. 192° [from (I) and HNCO],  $\beta$ -phenylcarbamido-, m.p. 174°,  $\beta$ -*o*-tolylcarbamido-, m.p. 172°,  $\beta$ -2-naphthylcarbamido-, m.p. 201°,  $\beta$ -*p*-nitrophenylcarbamido-, m.p. 202—203°,  $\beta$ -1-naphthylcarbamido-, m.p. 184—186°, and  $\beta$ -phenylthiocarbamido-, m.p. 158°,  $\beta$ -phenylpropionic acids;  $\beta$ -carbamido-, m.p. 193°,  $\beta$ -phenylcarbamido-, m.p. 167—168°,  $\beta$ -*o*-tolylcarbamido-, m.p. 180—181°,  $\beta$ -1- and -2-naphthylcarbamido-, m.p. 178° and 191°, respectively,  $\beta$ -*p*-nitrophenylcarbamido-, m.p. 171—172°,  $\beta$ -methylcarbamido-, m.p. 168—169° [from (II) and MeNCO],  $\beta$ -phenylthiocarbamido-, m.p. 146°, and  $\beta$ -*o*-tolylthiocarbamido-, m.p. 163°,  $\beta$ -anisylpropionic acids; 4-phenyl-, m.p. 217° (5-Br-derivative, m.p. 214°), 4-anisyl-, m.p. 228° [3'-Br-, m.p. 232°, and 5:3'-Br<sub>2</sub>- (III), m.p. 193—194°, derivatives], 1:4-diphenyl-, m.p. 226° (5-Br-derivative, m.p. 220—223°), 1-phenyl-4-anisyl- (IV), m.p. 210°, 4-anisyl-1-*o*-tolyl- (V), m.p. 181°, 4-phenyl-1- $\beta$ -naphthyl-, m.p. 240—241°, 4-anisyl-1- $\beta$ -naphthyl- (VI), m.p. 256—257°, 4-phenyl-1-*p*-nitrophenyl-, m.p. 253—254°, 1-*p*-nitrophenyl-4-anisyl- (VII), m.p. 268—269°, 4-phenyl-1- $\alpha$ -naphthyl-, m.p. 192—193°, 4-anisyl-1- $\alpha$ -naphthyl-, m.p. 218—219°, 4-phenyl-1-methyl-, m.p. 149—151°, and 4-anisyl-1-methyl-, m.p. 138°, 4:5-dihydrouacils; 6-keto-2-thion-4-phenyl-, m.p. 238° (S-Me derivative, m.p. 163.5°), 4-anisyl-, m.p. 228°, 1:4-diphenyl-, m.p. 243°, 4-phenyl-1-*o*-tolyl-, m.p. 188°, 1-phenyl-4-anisyl-, m.p. 231—232°, and 4-anisyl-1-*o*-tolyl-, m.p. 188°, hexahydropyrimidines; 4-phenyl-, m.p. 267°, and 1:4-diphenyl-, m.p. 292—294°, -uracils, obtained by elimination of HBr from the appropriate 5-Br-derivative with C<sub>6</sub>H<sub>5</sub>N (general procedure); 4-3'-bromo-4'-methoxyphenyluracil, m.p. 304—305° [from (III)]. Bromination of (IV) gives 1-phenyl-4-3'-bromo-4'-methoxyphenyl-4:5-dihydrouacil, m.p. 210°, and then the 5-Br-derivative, m.p. 242°, which yields 1-phenyl-4-3'-bromo-4'-methoxyphenyluracil, m.p. 326—328°. 1-*o*-Tolyl-4-3'-bromo-4'-methoxyphenyluracil, m.p. 312°, and 4:5-dihydrouacil, m.p. 178° (5-Br-derivative, m.p. 201°), are similarly obtained from (V). (VI) gives 4-3'-bromo-4'-methoxyphenyl-1- $\beta$ -naphthyl-4:5-dihydrouacil,

m.p. 238—239°, which could not be brominated further; similarly, (VII) affords 1-*p*-nitrophenyl-4-3'-bromo-4'-methoxyphenyl-4 : 5-dihydrouracil, m.p. 194—196°.

H. B.

**Synthesis of 2-amino-4-ethylpyrimidine.** W. T. CALDWELL and W. M. ZIEGLER (J. Amer. Chem. Soc., 1936, 58, 287—288).—6-Chloro-2-ethylthiol-4-ethylpyrimidine, b.p. 110—112°/4—5 mm. (from the 6-OH-derivative and POCl<sub>3</sub>), is reduced (Zn dust, aq. EtOH) to 2-ethylthiol-4-ethylpyrimidine, b.p. 105—107°/4 mm., hydrolysed (conc. HCl) to 2-hydroxy-4-ethylpyrimidine hydrochloride, m.p. 211—213° (decomp.) (sinters about 200°). This and POCl<sub>3</sub> give 2-chloro-4-ethylpyrimidine, b.p. 89—91°/7 mm., converted by EtOH-NH<sub>3</sub> at 120—130° into 2-amino-4-ethylpyrimidine (I), b.p. 229°, m.p. 140—141° (picrate, m.p. 194·5—195·5°; aurichloride, m.p. 98—99°). 2-Amino-6-hydroxy-4-ethylpyrimidine, m.p. 243—245° (decomp.) (from guanidine carbonate and EtCO·CH<sub>2</sub>·CO<sub>2</sub>Et in EtOH), and POCl<sub>3</sub> give the 6-Cl-derivative, m.p. 129—130°, reduced (Zn dust, aq. EtOH) to (I). (I) differs from 6-amino-4-ethylpyrimidine (this vol., 344); the structure of the latter is thus established.

H. B.

**Piria reaction. III. Mechanism.** W. M. LAUER, M. M. SPRUNG, and C. M. LANGKAMMERER (J. Amer. Chem. Soc., 1936, 58, 225—228).—The isolation of 1 : 5-dimethylbenziminazole [tartrate, m.p. 185·2—185·8° (decomp.)] in 18·3% yield from the NaHSO<sub>3</sub>-reduction products of 3-nitro-4-dimethylaminotoluene indicates the intermediate formation of the NO-derivative. If NO-compounds are formed in this way, then the Piria reaction (A., 1931, 720) should occur with either the NO<sub>2</sub>- or NO-derivative. In agreement with this view, reduction (Na<sub>2</sub>SO<sub>3</sub>, NaHSO<sub>3</sub>, or mixtures) of *p*-C<sub>6</sub>H<sub>4</sub>Me·NO gives *p*-C<sub>6</sub>H<sub>4</sub>Me·NH<sub>2</sub> (44—73%) and *p*-toluidine-3-sulphonic acid (I) (5·7—14·8%), i.e., the same products as are formed (*loc. cit.*) from *p*-C<sub>6</sub>H<sub>4</sub>Me·NO<sub>2</sub> (II). Details are given for the isolation of Na<sub>2</sub> 3-sulpho-4-methylphenylsulphamate (+H<sub>2</sub>O) (III), from the NaHSO<sub>3</sub>-reduction products of (II); (III) is hydrolysed (dil. HCl) to (I) in quant. yield. (III) is also prepared from (I) and 1-pyridiniumsulphonic acid (Baumgarten, A., 1926, 1130) in aq. Na<sub>2</sub>CO<sub>3</sub> at 10°; Na<sub>2</sub> *m*- and *p*-sulphophenyl-, 4-sulpho-2-methylphenyl- (+2H<sub>2</sub>O), and 4-sulpho-1-naphthyl- (+2H<sub>2</sub>O) -sulphamates are similarly prepared. Reduction (alkaline Na metabisulphite) of *p*-NO<sub>2</sub>·C<sub>6</sub>H<sub>4</sub>·OH gives *p*-NH<sub>2</sub>·C<sub>6</sub>H<sub>4</sub>·OH and 4-aminophenol-2-sulphonic acid [since deamination (diazo-method) and subsequent bromination affords *s*-C<sub>6</sub>H<sub>2</sub>Br<sub>3</sub>·OH]. 5-Nitrosalicylic acid similarly yields 5-amino- and 5-amino-3-sulphosalicylic acid (deamination and bromination gives *s*-C<sub>6</sub>H<sub>2</sub>Br<sub>3</sub>·OH). In these cases, SO<sub>3</sub>H is introduced *meta* to NH<sub>2</sub>, presumably owing to 1 : 4-addition of NaHSO<sub>3</sub> to the ·N·C·C·C· of the intermediate nitroso-phenol (as quinoneoxime). The Piria reaction on (II) thus involves the following reactions: (a)  $p\text{-C}_6\text{H}_4\text{Me}\cdot\text{NO}_2 \rightarrow p\text{-C}_6\text{H}_4\text{Me}\cdot\text{NO} \rightarrow p\text{-C}_6\text{H}_4\text{Me}\cdot\text{NH}\cdot\text{SO}_3\text{Na} \rightarrow p\text{-C}_6\text{H}_4\text{Me}\cdot\text{NH}_2$ ; (b)  $p\text{-C}_6\text{H}_4\text{Me}\cdot\text{NO} \rightarrow 2 : 4\text{-SO}_3\text{Na}\cdot\text{C}_6\text{H}_3\text{Me}\cdot\text{SO}_3\text{Na} \rightarrow \text{SO}_3\text{H}\cdot\text{C}_6\text{H}_3\text{Me}\cdot\text{NH}_2$ .

**Derivatives of quinazoline.** (Miss) T. M. REYNOLDS and R. ROBINSON (J.C.S., 1936, 196—199).—In part a reply to Späth (A., 1935, 873), and a detailed account of work already summarised (A., 1934, 1014). The following data are new: 3-allylquinazolinium iodide+0·33EtOH, m.p. 104—107° (picrate, m.p. 124°). When heated with MeNO<sub>2</sub> in EtOH, 4-hydroxy-3-allyl-3 : 4-dihydroquinazoline affords the 4-nitromethyl compound, isolated as its picrate, m.p. 152—153°, 4-nitromethyl-3-methyl-3 : 4-dihydroquinazoline, m.p. 137°, being obtained similarly. Passage of dry HCl into a mixture of HCO·NH<sub>2</sub>, 6-nitropiperonal, and C<sub>6</sub>H<sub>6</sub> at 60° affords 6-nitropiperonylidenediformamide, m.p. 248—250° (decomp.), converted by Zn dust-ice-AcOH into 6 : 7-methylenedioxyquinazoline, and, under certain conditions, into a non-diazotisable base, C<sub>9</sub>H<sub>6</sub>O<sub>3</sub>N<sub>2</sub>, m.p. 260—261°. (I) when refluxed with MeI in EtOAc gives 6 : 7-methylenedioxy-3-methylquinazolinium iodide, m.p. 239—240° (picrate, softens 183°, m.p. 185—186°), converted by AgCl into the chloride, hydrolysed by aq. KOH at 2—10° to 4-hydroxy-6 : 7-methylenedioxy-3-methyl-3 : 4-dihydroquinazoline, softens 154°, m.p. 158—159°, converted by MeNO<sub>2</sub> into the 4-nitromethyl, m.p. 159—160°, by COMe<sub>2</sub>-aq. Na<sub>2</sub>CO<sub>3</sub> into the 4-acetonyl compound (picrate, sinters 184°, m.p. 187°), and by boiling 2% NaOH into 6-aminopiperonal.

J. W. B.

**Reaction between benzoyl chloride and aromatic amines, and their products, compounds of the quinazoline series.** K. DZIEWONSKI and L. STERNBACH (Bull. Acad. Polonaise, 1935, A, 333—348).—*p*-C<sub>6</sub>H<sub>4</sub>Cl·NH<sub>2</sub> and BzCl with anhyd. ZnCl<sub>2</sub> at 180—200° afford 6-chloro-4-hydroxy-2 : 4-diphenyl-3-*p*-chlorophenyl-3 : 4-dihydro- (I), m.p. 159° (hydrochloride, m.p. 353°; picrate, m.p. 178°; Et ether, m.p. 225—226°), converted by heating at 250° into 6-chloro-2-hydroxy-2 : 4-diphenyl-3-*p*-chlorophenyl-2 : 3-dihydro-quinazoline (II), m.p. 199—201°. Hydrolysis of (I) or (II) with EtOH-HCl gives 5-chloro-2-benzamidobenzophenone (III), reconverted by SOCl<sub>2</sub> and *p*-C<sub>6</sub>H<sub>4</sub>Cl·NH<sub>2</sub> into (II). Diazotisation of 5-chloro-2-aminobenzophenone (IV) [by EtOH-H<sub>2</sub>SO<sub>4</sub> hydrolysis of (III)] and coupling with β-C<sub>10</sub>H<sub>7</sub>·OH gives 4-chloro-2-benzoylbenzeneazo-β-naphthol, m.p. 184—185°. With NH<sub>3</sub>-EtOH at 140° (I) gives 6-chloro-2 : 4-diphenylquinazoline, m.p. 190·5°. With NH<sub>2</sub>·OH·HCl in boiling EtOH (I) affords the oxime anhydride, C<sub>6</sub>H<sub>3</sub>Cl<CPh:N>O (V), m.p. 186—187°, but (II) gives the oxime, m.p. 163°, of (III). With HNO<sub>3</sub> (d 1·52) *p*-C<sub>6</sub>H<sub>4</sub>Cl·NHBz gives its 2-NO<sub>2</sub>-derivative, m.p. 132—133°, reduced by Zn-AcOH to 6-chloro-2-phenylbenziminazole (Fischer *et al.* A., 1906, i, 895), also obtained from (V) and EtOH-HCl at 150°. Diazotisation of (IV) and treatment with Na<sub>2</sub>SO<sub>3</sub>-NaOH at < 10° gives 5-chloro-2-hydroxy-3-phenylindazole, m.p. 113—114°, reduced (SnCl<sub>2</sub>-HCl) to 5-chloro-3-phenylindazole, m.p. 125—127°. By similar methods from the appropriate amine and BzCl are obtained 4-hydroxy-2 : 4-diphenyl-3-*p*-tolyl-6-methyl- +COMe<sub>2</sub>, m.p. 141°, and solvent-free, m.p. 148—149° (hydrochloride, m.p. 320°; picrate, m.p. 143°; Et ether, m.p. 161°), and -6 : 8-dimethyl-3 : 4-

*dihydro-* (VI), m.p. 163—164° (*picrate*, m.p. 204°), converted into *2-hydroxy-2:4-diphenyl-3-p-tolyl-6-methyl-2:3-dihydro-*, m.p. 194—195°, *2:4-diphenyl-6-methyl-*, m.p. 176°, and *-6:8-dimethyl-*, m.p. 152°, *-quinazoline*, and the *-6-methyl-*, m.p. 190°, and *-6:8-dimethyl-*, m.p. 180°, *-oximeanhydride* [both as (V)]. From (VI) are obtained *2-amino-3:5-dimethylbenzophenone*, m.p. 128.5°, and its *Bz* derivative, m.p. 162°, and *6-benzoyl-2:4-dimethylbenzenazo-β-naphthol*, m.p. 130.5°. J. W. B.

**Quinazolines. XLII. Synthesis of 3:4-dihydroquinazoline derivatives from *p*-aminobenzoic acid, formaldehyde, and hydrochloric acid.** S. E. CAIRNCROSS and M. T. BOGERT (Coll. Czech. Chem. Comm., 1936, 8, 57—65; cf. A., 1935, 1134).—*p*-NH<sub>2</sub>·C<sub>6</sub>H<sub>4</sub>·CO<sub>2</sub>Et, CH<sub>2</sub>O, and (a) HCl at 25° or (b) HCl-H<sub>2</sub>SO<sub>4</sub> at 70° give *Et*<sub>2</sub> *methylenebis-p-aminobenzoate*, m.p. 192—193°, converted by HCl-EtOH into *Et 3-p-carbethoxyphenyl-3:4-dihydroquinazoline-6-carboxylate* (I), m.p. 186—187°, also obtained in small amount in (b) above or in fair yield by condensation of *p*-NH<sub>2</sub>·C<sub>6</sub>H<sub>4</sub>·CO<sub>2</sub>H, CH<sub>2</sub>O, HCl, and H<sub>2</sub>SO<sub>4</sub> at 70° and subsequent esterification. (I) leads to the amorphous acid (*Na* salt), (CH<sub>2</sub>Cl·CH<sub>2</sub>)<sub>2</sub>, m.p. 173—174°, and *Me*<sub>3</sub> ester, m.p. 241—243°, which last with NEt<sub>2</sub>·CH<sub>2</sub>·CH<sub>2</sub>·ONa in C<sub>6</sub>H<sub>6</sub> affords the (NEt<sub>2</sub>·CH<sub>2</sub>·CH<sub>2</sub>)<sub>2</sub> ester, m.p. 114—115°, with anæsthetic properties. (I) and KMnO<sub>4</sub>-MgSO<sub>4</sub>-COMe<sub>2</sub> give *Et 3-p-carbethoxyphenyl-4-quinazoline-6-carboxylate*, m.p. 138.5—139.5°, also obtained from the 1-Et ester, m.p. 217—219° (lit. 216.5—218°), of 4:1:3-NH<sub>2</sub>·C<sub>6</sub>H<sub>3</sub>(CO<sub>2</sub>H)<sub>2</sub> and *Et formamidobenzoate* (prep. by 40% HCO<sub>2</sub>H at 80°), m.p. 147—148°, at 140—150°, a *product*, m.p. 182—183°, being also formed in the latter reaction. M.p. are corr. R. S. C.

**Bromo-derivatives of 4-hydroxy-2-thion-3-phenyl-1:2:3:4-tetrahydroquinazoline.** C. V. GHEORGHIU and (MLLE.) L. MANOLESCU (Bull. Soc. chim., 1936, [v], 3, 321—323).—5-Bromoisatin and PhNCS in NaOH-aq. EtOH give *6-bromo-4-hydroxy-2-thion-3-phenyl-1:2:3:4-tetrahydroquinazoline-4-carboxylic acid*, m.p. 156—161° (decomp. from 142°), giving with EtOH *6-bromo-2-thion-4-ethoxy-3-phenyl-1:2:3:4-tetrahydroquinazoline*, m.p. 197—204°, which in HClO<sub>4</sub> yields *6-bromo-4-hydroxy-2-thion-3-phenyl-1:2:3:4-tetrahydroquinazoline perchlorate* (formulated as 4-carbonium salt), *cryst.*, red. R. S. C.

**Phenazine series. III. Isomeric octahydrophenazines.** G. R. CLEMO and H. McILWAIN (J.C.S., 1936, 258—261).—Reduction of 1:2:3:4-tetrahydrophenazine (I) with Na-EtOH affords the (?) *trans-1:2:3:4:9:10:11:12-H<sub>8</sub>-derivative* (II), m.p. 156° (A., 1935, 991, gives m.p. 150°), but with H<sub>2</sub>-Pd-C at room temp./100 lb. per sq. in., the (?) *cis-1:2:3:4:9:10:11:12-H<sub>8</sub>-derivative* (III), m.p. 147°, is obtained. Reduction of (I) with H<sub>2</sub>-catalyst B [Ni from Ni(OH)<sub>2</sub> at 370—380° by Rupe's method] at 180° gives mainly (II) and a little (III), but with catalyst A [Ni from Ni(NO<sub>3</sub>)<sub>2</sub> at 300—310° by Gattermann's method] at 180°, the product is the 1:2:3:4:5:6:7:8-H<sub>8</sub>-derivative (IV), m.p. 109° (Wallach *et al.*, A., 1924, i, 862). The geometrical

isomerism of (II) and (III) is proved since both have the properties of an *o*-C<sub>6</sub>H<sub>4</sub>(NH<sub>2</sub>)<sub>2</sub> and both give (NO)<sub>2</sub>-derivatives with H<sub>2</sub>SO<sub>4</sub>-NaNO<sub>2</sub>, (II) giving a (NO)<sub>2</sub>-derivative, m.p. 126°, and (III) an (NO)<sub>2</sub>-derivative, m.p. 109°, whereas (IV) gives no NO-derivative. (I), (II), (III), and (IV) are all dehydrogenated, by Pd-C at 200°, to phenazine. (II) is unchanged by treatment with Na-EtOH, H<sub>2</sub>-Pd-AcOH, or when passed over catalyst-B at 180°, but with catalyst-A it is converted into (IV). (III) is unchanged by treatment with Na-EtOH or H<sub>2</sub>-Pd-AcOH, but passage of its vapour over catalyst-A at 180° converts it into (IV), and, over catalyst-B at 180°, partial conversion into (II) occurs.

J. W. B.

**Hydroxy-compounds of the anthrapyrimidine series.**—See B., 1936, 182.

**Alkylated iminazoles of high mol. wt.**—See B., 1936, 183.

**New cleavage product of guanine.** G. HUNTER (Nature, 1936, 137, 405).—When guanine is auto-cleaved with an acid, approx. 20% is converted into C<sub>4</sub>H<sub>7</sub>N<sub>5</sub>, probably 4- (or 5-)guanidinoglyoxaline. Reactions are described. L. S. T.

**Function of halogens in hæmin.** K. LINDENFELD (Rocz. Chem., 1935, 15, 516—542).—The reaction between hæmin (HmCl) and MX (M=a cation, X=Br, I, CNS, HCO<sub>2</sub>) in C<sub>5</sub>H<sub>5</sub>N-AcOH is HmCl+X'=HmX+Cl'; C<sub>5</sub>H<sub>5</sub>N (or quinine) merely acts as a solvent, since diethylhæmin in CHCl<sub>3</sub>-AcOH undergoes the same changes in absence of the bases, and HmCl may be recovered unchanged from C<sub>5</sub>H<sub>5</sub>N solutions. The prep. and properties of *formylhæmin* are described; *acetylhæmin* cannot be obtained by the above reaction. It is concluded that the Cl linking is heteropolar. R. T.

**Preparation of cryptoxanthine from paprika.** L. VON CHOLNOKY (Magyar chem. Fol., 1934, 40, 85—89; Chem. Zentr., 1935, ii, 230; cf. A., 1934, 657).—A chromatographic separation is described. H. N. R.

**Abnormal reactions of hydroxylamine.** P. DREYFUSS (Rend. Semin. Fac. Sci. Univ. Cagliari, 1934, 4, 55—58; Chem. Zentr., 1935, ii, 46).—Formulae are proposed for the compound obtained from NH<sub>2</sub>OH and dibenzylidencyclohexanone (Poggi and Saltini, A., 1934, 773) and that from phorone and NH<sub>2</sub>OH (Vorländer and Gästner, A., 1899, i, 259). 4:5:4':5'-Tetramethoxy-2:2'-dibenzoylbenzophenone yields a compound with NH<sub>2</sub>OH (formula suggested). H. N. R.

**Chemistry of the antineuritic vitamin.** K. MAKINO and I. IMAI (Z. physiol. Chem., 1936, 239, I—II).—The constitutions

for the antineuritic vitamin (I) and

$\text{CH} \begin{array}{c} \text{NH} \text{---} \text{CO} \\ \diagup \quad \diagdown \\ \text{N-CH(OH)} \end{array} \text{C}(\text{NO}_2) \cdot \text{CH}_2 \cdot \text{OEt}$  for the nitrate obtained therefrom (cf. Windaus *et al.*, this vol., 253) are suggested as alternative structures. The oxidation of (I) by K<sub>3</sub>Fe(CN)<sub>6</sub> and NaOH to thiochrome can then be explained by simple analogy. H. W.

**Carbocyanine dyes.**—See B., 1936, 184.

**Nornicotine.** A. WENUSCH (Pharm. Zentr., 1936, 77, 141—143).—There is relatively little nornicotine (I) in the smoke from tobacco rich therein; oxidation of (I) either by  $\text{KMnO}_4$  or during smoking gives an alkaloid (picrate, m.p. 217—218°) resembling myosmine. (I) is less toxic than nicotine. R. S. C.

**d-Nornicotine.** E. SPATH, C. S. HICKS, and E. ZAJIC (Ber., 1936, 69, [B], 250—251).—Partly racemised *d*-nornicotine (A., 1935, 1136) is purified by conversion into the perchlorate, which is crystallised from  $\text{MeOH-Et}_2\text{O}$ . The most active portion has  $[\alpha]_D^{20} +86.3^\circ$ , whereas the optically pure substance has  $[\alpha]_D^{25} +88.8^\circ$ . H. W.

**Tobacco bases. IV. Syntheses of l-nornicotine.** E. SPATH, L. MARION, and E. ZAJIC. V. **Constitution of myosmine.** E. SPATH, A. WENUSCH, and E. ZAJIC (Ber., 1936, 69, [B], 251—255, 393—396).—IV. *l*-Nicotine (I) is cautiously oxidised with  $\text{KMnO}_4$  and the more strongly basic portions are removed from the product by fractional extraction with HCl. They are then distilled with steam in vac., whereby (I) is volatilised. The residue is transformed into the dipicrate, from which, after repeated crystallisation, *l*-nornicotine (II),  $[\alpha]_D^{20} -76.1^\circ$ , raised to  $-83.2^\circ$  after further purification through the perchlorate, is isolated. Treatment of (I) with  $\text{Ag}_2\text{O}$  and of the product dissolved in  $\text{Et}_2\text{O}$  with aq. NaCl containing HCl gives a most strongly basic fraction from which (II),  $[\alpha]_D^{20} -88.8^\circ$ , is isolated.

V. Myosmine (III), after purification through the picrate, m.p. 182—183° (vac.), has m.p. 42—43° (vac.), and is optically inactive in MeOH ( $c=20$ ). It is dehydrogenated by Pd sponge at 200° to 2-3'-pyridylpyrrole. Its composition, optical inactivity (assuming that it is not a racemate and hence does not contain an asymmetric C atom), and conversion by  $\text{Bz}_2\text{O}$  in abs.  $\text{Et}_2\text{O}$  with opening of the ring into (?) 3- $\gamma$ -benzamido butyrylpyridine, m.p. 118°, suggest formula (III). H. W.

**Constitution of solanidine from Solanum sodomaeum.** G. ODDO and G. CARONNA (Ber., 1936, 69, [B], 283—287).—The action of  $\text{HNO}_2$  on solanidine-*s* (I) gives azosolanidine (II), m.p. 260° (decomp.), which decolorises  $\text{Br-H}_2\text{O}$  and does not give the Liebermann reaction, and a quinhydrone  $\text{C}_{18}\text{H}_{23}\text{O}_2\text{N} \cdot \text{C}_{18}\text{H}_{31}\text{ON}$ , m.p. 120°, decomposed by HCl into the hydrochloride of (I) and the quinone,  $\text{C}_{16}\text{H}_{25}\text{N}(\text{CO})_2$ . The reactions described by Oddo *et al.* (A., 1911, i, 671; 1914, i, 1174) are therefore interpreted thus:

$\text{C}_{16}\text{H}_{28} \cdot \text{CX}(\text{OH}) \cdot \text{CH}_2\text{Cl}$  (chlorohydroxysolanidane). The formation of (III) is established by the production of *tetra-acetylsolanidine*,  $\text{NAc}_2 \cdot \text{C}_{16}\text{H}_{26} \cdot \text{CHX} \cdot \text{CH}(\text{OAc})_2$ , m.p. 253° (acetate) by the action of  $\text{AcOH-Ac}_2\text{O-H}_2\text{SO}_4$  on (I). Attempts to remove Cl from (IV) by Zn and AcOH, Na and EtOH or amyl alcohol, or through the Mg compound were unsuccessful. (IV) is smoothly oxidised by  $\text{CrO}_3$  in AcOH or by  $\text{KMnO}_4$  in  $\text{COMe}_2$ ; with molten KOH it affords a monocarboxylic acid and a neutral substance, m.p. 145°. Since solanidine-*t* differs from (I) in the possession of  $\text{C}_7\text{H}_7$  and a *tert.* N, it is suggested that it may be *N*-benzylsolanidine-*s* and that (I) is therefore the parent of all the solanidines, which differ by the presence of alkyl or aryl attached to N or to the carbocyclic groups. H. W.

**Phenyl- $\psi$ -pelletierine.** B. K. BLOUNT (J.C.S., 1936, 287—288).—Dropwise addition of NaOMe-MeOH to a solution of  $\text{CH}_2\text{Ph} \cdot \text{CHO}$  and  $\text{CH}_3 \cdot \text{CH} \cdot \text{CHO}$  in MeOH at  $-18^\circ$  to  $0^\circ$  affords  $\text{CHO} \cdot [\text{CH}_2]_3 \cdot \text{CHPh} \cdot \text{CHO}$  in solution, condensed with  $\text{CO}(\text{CH}_2 \cdot \text{CO}_2\text{H})_2 \cdot \text{CaCO}_3$ -aq. MeOH-33%  $\text{NH}_2\text{Me}$  to give 6-phenylgranatan-3-one (phenyl- $\psi$ -pelletierine), isolated as its 2:4-dipiperonylidene derivative, m.p. 210°. J. W. B.

**Synthetic experiments on eserine. V. Synthesis of l-eserethole.** T. HOSHINO and T. KOBAYASHI (Proc. Imp. Acad. Tokyo, 1935, 11, 416—417; cf. A., 1935, 1256, 1378).—*dl*-Eserethole and *d*-tartaric acid in EtOH give the *d*-tartrate, m.p. 173—174°,  $[\alpha]_D^{15} +115^\circ$  in  $\text{H}_2\text{O}$ , of the *d*-base and the mother-liquors with the *l*-acid give the *l*-tartrate, m.p. 173—174°,  $[\alpha]_D^{15} -115^\circ$  in  $\text{H}_2\text{O}$ , of the *l*-base. The active picrates melt at 135—136°, the *dl*-picrate at 151—152°. R. S. C.

**Synthesis of bicuculline.** I. P. W. G. GROENEWOLD and R. ROBINSON (J.C.S., 1936, 199—202).—Bromonormeconin when heated with methylene sulphate in aq.  $\text{COMe}_2\text{-NaOH}$  ( $\text{N}_2$  atm.) affords 6-bromo-3:4-methylenedioxyphthalide, m.p. 196°, reduced (Al-Hg in boiling EtOH, Zn dust-aq. NaOH, or  $\text{N}_2\text{H}_4 \cdot \text{H}_2\text{O-Pd-SrCO}_3\text{-EtOH-KOH}$ ) to 3:4-methylenedioxyphthalide, converted by  $\text{HNO}_3$  ( $d$  1.42) at  $0^\circ$  into its 6- $\text{NO}_2$ -derivative (I), m.p. 222—223°, which with cotarnine in EtOH gives anhydrocotarnine-6-nitro-, m.p. 177—178°, reduced ( $\text{SnCl}_2\text{-HCl}$  at  $0^\circ$ ) to anhydrocotarnine-6-amino-3:4-methylenedioxyphthalide, m.p. 204—205° (decomp.). Local similarly condenses with (I) to give nitro-*x*-adlumine (anhydroloidal-6-nitro-3:4-methylenedioxyphthalide), m.p. 180—181° (decomp.), reduced to the  $\text{NH}_2$ -derivative, m.p. 218—219°. Hydrastinine and (I) afford nitro-*x*-bicuculline, sinters at 176°, blackens at 179°, reduced to the  $\text{NH}_2$ -compound, m.p. 203—204°. Diazotisation of this and treatment with aq. KI affords iodo-*x*-bicuculline, m.p. 208—209°, reduced (Al-Hg in boiling EtOH- $\text{C}_6\text{H}_6$ ) to *x*-bicuculline (anhydrohydrastinine-3:4-methylenedioxyphthalide), m.p. 215°, resolution of which gives the *d*-form, identical with the natural alkaloid (details later). J. W. B.

**Ergot alkaloids. Structure of lysergic acid.** W. A. JACOBS and L. C. CRAIG (Science, 1936, 83, 38—39).—The previous structure suggested for lysergic

acid (A., 1935, 1512) is revised to (I). The base,  $C_{11}H_{11}N$ , obtained by the alkali fusion of dihydrolysergic acid (II) is 1:5- $C_{10}H_6Me \cdot NH_2$ . The tribasic acid,  $C_{14}H_9O_8N$  (A., 1932, 1147), yields quinoline on distillation with soda-lime, and  $HNO_3$  oxidation of (I) yields picric acid. Catalytic hydrogenation of (I) produces (II) which, unlike (I), can no longer be titrated, indicating the proximity of the double linking and  $CO_2H$  in the ring containing NMe. Further hydrogenation appears to attack the indole ring system.

L. S. T.  
**Spectroscopic similarity between ergot (lysergic acid) and the yohimbine alkaloids.** M. S. KHARASCH, D. W. STANGER, M. A. BLOODGOOD, and R. R. LEGAULT (Science, 1936, 83, 36—38).—The marked similarity observed between the mol. absorption curves for ergotamine, ergotamine, and ergotocine (I) indicates a common structural skeleton, lysergic acid, responsible for their ultra-violet absorptions. Comparison of the curve for (I) with those of harmol, harmine, harmaline, and methyl- and tetrahydro-harmine indicates no structural relationship between (I) and the harmala alkaloids. The curve of yohimbine (II) is markedly similar to that of (I) in shape, but displaced toward shorter  $\lambda$ , whilst those of (II) and hydrogenated (I) are practically identical.

L. S. T.

**New ergot alkaloid.** M. S. KHARASCH, H. KING, A. STOLL, and M. R. THOMPSON (Nature, 1936, 137, 403, and Science, 1936, 83, 206—207).—Ergometrine, ergotocine, ergobasine, and ergostetrine are identical.

L. S. T.

**Peganine.** IX. Syntheses of  $\Delta^9$ -pegene and peganine. E. SPÄTH and N. PLATZER. X. *l*-Peganine (*l*-vasicine) from *Adhatoda vasica*, Nees. E. SPÄTH and F. KESZTLER. XI.  $\Delta^9$ -Pegen-1-one. E. SPÄTH and N. PLATZER (Ber., 1936, 69, [B], 255—257, 384—386, 387—393).—IX.  $o$ - $NH_2 \cdot C_6H_4 \cdot CH_2 \cdot NH_2$  and  $\gamma$ -butyrolactone (I) are heated at  $200^\circ$  in  $N_2$  with intermittent removal of the  $H_2O$  formed and the product is heated with  $POCl_3$ , whereby  $\Delta^9$ -pegene, m.p.  $99$ — $100^\circ$ , is obtained. It is transformed by the successive action of red P and Br and  $Ba(OH)_2$  into  $\alpha$ -hydroxybutyrolactone, b.p.  $128$ — $130^\circ/0.5$  mm., which affords peganine when heated with  $o$ - $NH_2 \cdot C_6H_4 \cdot CH_2 \cdot NH_2$  at  $200^\circ$ .

X. The dry leaves are extracted with EtOH at  $15$ — $20^\circ$ , the extracts are conc. in vac., acidified with 1% AcOH, freed from residual EtOH, rendered ammoniacal, and extracted with  $Et_2O$ . The crude base is treated with  $CHCl_3$ , in which peganine dissolves, leaving a small residue. Treatment of the alkaloid with AcOH followed by  $NH_3$  and crystallisation from  $Et_2O$  gives *l*-peganin (I) identical with the synthetic material. The natural alkaloid is therefore optically active, and its isolation in the inactive form is due to racemisation during extraction. (I) had  $[\alpha]_D^{25} -254^\circ$  in pure  $CHCl_3$ ,  $[\alpha]_D^{25} -61.5^\circ$  in abs. EtOH,  $[\alpha]_D^{25} +19.5^\circ$  as sulphate in  $H_2O$ . The optical activity in  $CHCl_3$  is strongly influenced by the presence of very small amounts of EtOH.

XI. Mainly corrections of the work of Juneja *et al.* (A., 1935, 765, 995).  $o$ - $NO_2 \cdot C_6H_4 \cdot CH_2 \cdot NH_2$  and  $(\cdot CH_2 \cdot CO)_2O$  in  $Et_2O$  and subsequently at  $100^\circ$  give succin-*o*-nitrobenzylamic acid (II), m.p.  $123$ — $124^\circ$ , which passes when distilled in a high vac. into succin-*o*-nitrobenzylimide (III), m.p.  $133^\circ$ . Reduction of (II) with  $FeSO_4 \cdot NH_3$  affords succin-*o*-amino-benzylamic acid, m.p.  $145^\circ$ , which passes when heated at  $180$ — $190^\circ/0.04$  mm., or with anhyd. NaOAc in  $H_2$  at  $140$ — $150^\circ$  into  $\Delta^9$ -pegen-1-one (IV), m.p.  $191^\circ$  (vac.). Alternatively, (III) is obtained from  $(\cdot CH_2 \cdot CO)_2NK$ ,  $o$ - $NO_2 \cdot C_6H_4 \cdot CH_2Cl$ , and NaCl at  $130^\circ$  and reduced by  $SnCl_2$  and HCl ( $d$  1.16) to (IV) and  $\beta$ -3:4-dihydro-2-quinazolypropionic acid, m.p.  $228$ — $230^\circ$ . Reduction of (III) with Zn turnings and 10%  $H_2SO_4$  at  $20$ — $25^\circ$  affords succin-*o*-aminobenzylimide, m.p.  $106$ — $107^\circ$ , which passes at  $230$ — $240^\circ/30$  mm. into (IV). Electrolytic reduction of (III) at a Pb cathode gives not pegane, but 1-*o*-aminobenzylpyrrolidine, m.p.  $30$ — $31^\circ$  (picrolonate, m.p.  $204$ — $206^\circ$ ). Pegane is obtained from (IV) by reduction with Na and boiling amyl alcohol.

H. W.

**Synthesis of papaverine derivatives.** II. **Synthesis of 1-(3':4':5'-trimethylphenyl)-6:7-diethoxyisoquinoline.** S. SUGASAWA (J. Pharm. Soc. Japan, 1935, 55, 224—233).—3:4-Dimethoxyhippuric acid and Cu chromite in quinoline afford  $\omega$ -benzamido-3:4-dimethoxystyrene, m.p.  $138^\circ$ , reduced catalytically to  $\beta$ -(3:4-dimethoxyphenyl)ethylbenzamide, m.p.  $90^\circ$  (also by benzoylation of 3:4-dimethoxy- $\beta$ -phenylethylamine). With  $POCl_3$ , this yields 6:7-dimethoxy-1-phenyl-3:4-dihydroisoquinoline, m.p.  $120$ — $121^\circ$ . Trimethylgalloyl chloride and aminoacetonitrile sulphate yield *Et* galloylglucynonitrile  $Me_3$  ether, m.p.  $186$ — $187^\circ$ , hydrolysed to galloylglucynonitrile  $Me_3$  ether, m.p.  $218^\circ$ . This with 3:4-diethoxybenzaldehyde gives 2-(3':4':5'-trimethoxyphenyl)-4-(3':4'-diethoxybenzylidene)oxazolone, m.p.  $163$ — $164^\circ$ . With NaOH this affords 3:4:5-trimethoxy-3':4'-diethoxybenzylidenehippuric acid, m.p.  $220$ — $221^\circ$ , which, with Cu chromite in quinoline, yields  $\omega$ -galloylamido-3:4-diethoxystyrene  $Me_3$  ether, m.p.  $157$ — $158^\circ$ , reduced catalytically to N-[ $\beta$ -(3:4-diethoxyphenyl)ethyl]galloylamine  $Me_3$  ether, m.p.  $130$ — $131^\circ$ . This, with  $POCl_3$ , affords 6:7-diethoxy-1-(3':4':5'-trimethoxyphenyl)-3:4-dihydroisoquinoline, m.p.  $163$ — $164^\circ$ , which, with Pd in xylene, yields 6:7-diethoxy-1-(3':4':5'-trimethoxyphenyl)isoquinoline, m.p.  $117$ — $118^\circ$ .

CH. ABS. (r)

**Synthesis of benzyltetrahydroisoquinoline bases under so-called physiological conditions.** E. SPÄTH, F. KUFFNER, and F. KESZTLER (Ber., 1936, 69, [B], 378—384).—Homopiperonylhomopiperonylamide is converted by successive treatment with  $POCl_3$  in PhMe and Zn and fuming HCl into 6:7:3':4'-dimethylenedioxybenzyl-1:2:3:4-tetrahydroisoquinoline (I), m.p.  $84$ — $85^\circ$  [hydrochloride, m.p.  $242$ — $243^\circ$  (vac.)], the presence of minute amounts of which can be detected by its transformation by  $CH_2O$  in MeOH into 2:3:12:13-dimethylenedioxyberbine (II), m.p.  $214^\circ$  (vac.). Homopiperonal (III) is obtained by the action of dry  $AgOBz$  and I in boiling  $C_6H_6$  on saffrole and treatment of the product with boiling NaOH-50% MeOH, whereby

safrole glycol is obtained, which is oxidised by  $\text{Pb}(\text{OAc})_4$ . When (III) is condensed with homopiperonylamine hydrochloride (Hahn *et al.*, A., 1935, 357) the products are: (I) homopiperonylamine, which cannot contain (I), since the compounds are readily separated from one another by distillation in a high vacuum, (2) 3':4'-methylenedioxybenzylidene- $\beta$ -3:4-phenylethylamine (IV), m.p. 115–117°, the formation of which is attributed to the presence of a trace of piperonal in (III), and (3) a non-cryst. material converted by  $\text{CH}_2\text{O}$  into norhydrohydrastinine unaccompanied by any trace of (II). It is therefore impossible that (I) is produced as reported by Hahn *et al.* (*loc. cit.*) and their product is very probably impure (IV). H. W.

**Hydrates of quinine.** G. MALQUORI and M. COVELLO (Annali Chim. Appl., 1935, 25, 647–654).—Neither the trihydrate nor the known higher hydrates can exist above 15°. Dehydration appears to be a discontinuous process, but definite hydrates do not result. Dehydration is complete at 50–60° and is "irreversible." A. M. P.

**Origin of  $\beta$ -isocupreidine.** R. LUDWICZAK and J. SUSZKO (Bull. Acad. Polonaise, 1935, A, 104–106).—A correction to previous work (A., 1935, 996) based on the observation that, when heated with  $\text{H}_2\text{SO}_4$ , hydrocupreidine is unchanged but cupreidine is partly converted (equilibrium) into  $\beta$ -isocupreidine. J. W. B.

**Hydriodoquinine and niquine.** J. REYMAN and J. SUSZKO (Bull. Acad. Polonaise, 1935, A, 360–373).—Hydriodoquinine-I (A)  $+\text{C}_6\text{H}_6$ , m.p. 93°, resolidifies and decomp. 130–140°,  $[\alpha]_D^{20} -18^\circ$  (Rosenmund *et al.*, A., 1924, i, 982) (methiodide, m.p. 112–114°,  $[\alpha]_D^{20} -82.5^\circ$ ), is decomposed in boiling  $\text{C}_6\text{H}_6$  to give  $\beta$ -isoquinine (B) (not isolated) and an insol. basic hydriodide,  $(\text{C}_{20}\text{H}_{25}\text{O}_2\text{N}_2\text{I})_2\text{HI}$  (C), m.p. 178–204° (decomp.), reconverted into (A) by  $\text{NH}_3$ ; but (A) is unaltered by hot P-HI (*d* 1.7) and, contrary to Skrap (ref., *loc. cit.*) is converted into (B) by  $\text{AgNO}_3$ . Hydriodoquinine-II (D), decomp. 125–150°,  $[\alpha]_D^{20} -217^\circ$ , is similarly decomposed in boiling  $\text{C}_6\text{H}_6$  to the insol. basic hydriodide (E)  $+\text{CHCl}_3$ , m.p. 76–80°, and solvent-free, m.p. 175–192° (decomp.),  $[\alpha]_D^{20} -87^\circ$  [reconverted into (D) by cold  $\text{NH}_3$ ] and (from the mother-liquor) niquine (F):  $3\text{C}_{20}\text{H}_{25}\text{O}_2\text{N}_2\text{I} \rightarrow (\text{C}_{20}\text{H}_{25}\text{O}_2\text{N}_2\text{I})_2\text{HI} + \text{C}_{20}\text{H}_{24}\text{O}_2\text{N}_2$ . (E) is also obtained from (D) (3 mols.) and its dihydriodide, m.p. 223° (decomp.) (1 mol.). Although it could not be prepared by admixture of (A) and (D), decomp. of the mixed hydriodides of (A) and (D) with  $\text{NH}_3$  in presence of  $\text{C}_6\text{H}_6$  affords a mol. compound, m.p. 93°,  $[\alpha]_D^{20} -118^\circ$  [methiodide, m.p. 191–195° (decomp.)]. Thus (A) and (D) are only stereoisomerides, but (B) and (F) are structural isomerides, both of composition  $\text{C}_{20}\text{H}_{24}\text{O}_2\text{N}_2$ . With  $\text{AcCl}-\text{C}_5\text{H}_5\text{N}$  (F) gives a  $\text{Ac}_5$  derivative, m.p. 142–143°  $[\alpha]_D^{20} +33^\circ$ , partly hydrolysed by 20% HCl at room temp. to the known  $\text{Ac}_1$  derivative: hence (F) contains a OH. Oxidation of (F) with  $\text{H}_2\text{O}_2$  at 100° gives quinic acid. All  $[\alpha]_D$  vals. are in 96% EtOH. J. W. B.

**Quinine-urethane solutions.** L. NOBILI (G. Farm. Chim., 1935, 84, 15–20; Chem. Zentr., 1935,

i, 3955).—The greenish-yellow colour is said to be due to the presence of a  $\text{CH}_2\text{OH}$  in quinine.

H. N. R.

**Niquidine.** T. DOMAŃSKI and J. SUSZKO (Bull. Acad. Polonaise, 1935, A, 457–464).—Quinidine with conc. HCl or HBr (cf. A., 1935, 874, 1137) gives an unsaturated alkaloid, *niquidine* (I),  $\text{C}_{19}\text{H}_{24}\text{N}_2\text{O}_2$ , m.p. 161°,  $[\alpha]_D^{20} +171^\circ$  in EtOH [dioxalate, m.p. 206–207° (decomp.),  $[\alpha]_D^{20} +189^\circ$  in  $\text{H}_2\text{O}$ ; dihydrobromide, m.p. 250° (decomp.); N-NO-derivative, m.p. 80–130°, decomp. 160–170°,  $[\alpha]_D^{20} -73^\circ$  in EtOH; dibromide, m.p. 170–171° (decomp.),  $[\alpha]_D^{20} +142^\circ$  in MeOH [dihydrobromide, m.p. 238° (decomp.),  $[\alpha]_D^{20} +152^\circ$  in MeOH and  $\text{H}_2\text{O}$ ; dinitrate, m.p. 186–187° (decomp.)]; N-Ac, m.p. 206–207°,  $[\alpha]_D^{20} +25^\circ$  in EtOH; and N-Ac<sub>2</sub>, m.p. 80–90°,  $[\alpha]_D^{20} -28^\circ$  in EtOH, derivatives. (I) with 25% AcOH in a sealed tube gives *nichotoxin* (*nichicin*) (II), m.p. 70°,  $[\alpha]_D^{20} -5^\circ$  (p-nitrophenylhydrazone, m.p. about 60°), and with  $\text{H}_2\text{O}_2$  yields quinic acid. (I) may be as shown

$$\begin{array}{c} \text{CH}_2\text{CH}(\text{CH}_2\text{CH}(\text{CH}_2)_2\text{CH}(\text{OH})\text{C}_5\text{H}_5\text{N}\cdot\text{OMe}) \\ | \\ \text{CH}_2\text{N}(\text{CH}_2)_2\text{CH}(\text{CH}_2\text{NH}_2)(\text{CH}_2\text{CO}\cdot\text{C}_5\text{H}_5\text{N}\cdot\text{OMe}) \end{array}$$

and (II)  $\text{C}_7\text{H}_{10}(\text{CH}_2\cdot\text{NH}_2)(\text{CH}_2\cdot\text{CO}\cdot\text{C}_5\text{H}_5\text{N}\cdot\text{OMe})$ .

F. R. G.

**Transformations of isoquinidines.** T. DOMAŃSKI and J. SUSZKO (Bull. Acad. Polonaise, 1935, A, 465–473).—Quinidine,  $\alpha$ -,  $\beta$ -, and  $\gamma$ -isoquinidine, nichidine, and the corresponding toxins (cf. preceding abstract) are interconvertible in presence of acids.

F. R. G.

**Addition of organomagnesium halides to  $\psi$ -codeine types.** I. Deoxycodine-C. L. SMALL and K. C. YUEN (J. Amer. Chem. Soc., 1936, 58, 192–196).—Deoxycodine-C (I) (*salicylate*, m.p. 195–196°) (A., 1931, 1077) and  $\text{MgMeI}$  give the phenolic methyl-dihydrodeoxycodine (II), m.p. 145–146°,  $[\alpha]_D^{20} +69.7^\circ$  in EtOH or  $\text{CHCl}_3$  (hydrobromide, m.p. 245–246°; hydriodide, m.p. 155–158°; methiodide, m.p. 239°), presumably formed by 1:2- or 1:4-addition involving the  $\cdot\text{O}$  linking. Zn dust distillation of (II) gives a hydrocarbon,  $\text{C}_{15}\text{H}_{12}$ , m.p. 103° (not sharp; sinters from 95°) [picrate, m.p. 95–98° (sinters from about 85°)], and oily hydrocarbon(s) (picrates, m.p. 118–119° and 138–141°, not identical with 2- and 4-methylphenanthrene picrates). Hydrogenation of (II) affords methyl-tetrahydrodeoxycodine, m.p. 128–129°,  $[\alpha]_D^{20} -47.8^\circ$  in EtOH [hydrochloride, m.p. 240.5°; hydrobromide, m.p. 248–249°; methiodide (+EtOH), m.p. 254–255°]. (I) and  $\text{MgEtI}$  give  $\alpha$ -ethyl-dihydrodeoxycodine (III), m.p. 156–164°,  $[\alpha]_D^{20} -184.2^\circ$  in  $\text{CHCl}_3$  (hydriodide, m.p. 205–210°; perchlorate, m.p. 187–200°; methiodide, m.p. 210–215°), and an oily product (A). (III) and (A) are reduced ( $\text{H}_2$ ,  $\text{PtO}_2$ , aq. MeOH, N-HCl) to  $\alpha$ -, m.p. 168.5–169°,  $[\alpha]_D^{20} -54.8^\circ$  in  $\text{CHCl}_3$  (hydriodide, m.p. 234°), and  $\beta$ -, m.p. 148–153°,  $[\alpha]_D^{20} -37.6^\circ$  in  $\text{CHCl}_3$ , -ethyl-tetrahydrodeoxycodines, respectively; (A) also gives an unidentified substance, m.p. 215–216°. The isomerism may be configurational or positional. (I) and  $\text{MgPhBr}$  afford  $\approx 83\%$  of phenyl-dihydrodeoxycodine (IV), m.p. 184.5–185.5°,  $[\alpha]_D^{20} +129.3^\circ$  in  $\text{CHCl}_3$  [picrate (+ $\text{H}_2\text{O}$ ), m.p. (anhyd.) 129–132°; benzoate, m.p. 203–204°; methiodide, m.p. 257.5–258°], and a little of an oil (B).

(IV) could not be reduced catalytically except with  $\text{PtO}_2$  in aq.  $\text{MeOH-HCl}$ ; a *hexahydrophenylltetrahydrodeoxycodeine* (V), m.p. 132—134°,  $[\alpha]_D^{24} -48.4^\circ$  in  $\text{CHCl}_3$  (perchlorate, m.p. 255—256°; *methiodide*, m.p. 250°), results. (B) is reduced to a *phenylltetrahydrodeoxycodeine*, m.p. 218—220°,  $[\alpha]_D^{26} +16.1^\circ$  in  $\text{CHCl}_3$ . *cyclohexyldihydrodeoxycodeine*, m.p. 131.5—132.5°,  $[\alpha]_D^{25} -51^\circ$  in  $\text{CHCl}_3$  (perchlorate, m.p. 250—251°), prepared from (I) and  $\text{Mg}$  cyclohexyl chloride in isoamyl ether (not obtained in  $\text{Et}_2\text{O}$ ) at 100°, is reduced [as for (IV)] to *cyclohexylltetrahydrodeoxycodeine*, m.p. 193—193.5°,  $[\alpha]_D^{25} -14.2^\circ$  in  $\text{CHCl}_3$  (*hydriodide*, m.p. 235—236°), which differs from (V).

H. B.

#### Alkaloids of *Sinomenium* and *Cocculus*. XL. Alkaloids of *Stephania cepharantha*, Hayata.

III. H. KONDO and I. KEMATSU (J. Pharm. Soc. Japan, 1935, 55, 234—241).—*isoTetrandrine* (I),  $\text{C}_{38}\text{H}_{42}\text{O}_6\text{N}_2$ , m.p. 181—182°,  $[\alpha]_D^{17} +146^\circ$  in  $\text{CHCl}_3$ , isolated from the above, yields a *methiodide*, decomp. 242°, an  $\alpha$ -, m.p. 171—172° [*methiodide* (II), decomp. 255°], and a  $\beta$ -, m.p. about 110°, *methine*. (II) with  $\text{MeOH-KOH}$  affords *de-N-isotetrandrine*, m.p. 220°, not depressed on admixture with *de-N-tetrandrine* or *de-N-berbamine* methylate.  $\text{KMnO}_4$  oxidises (II) to a *substance*, m.p. 305°, not depressed on admixture with  $\text{Et}_2$  6-methoxydiphenyl-3:4'-dicarboxylate. The partial formula  $\text{C}_{32}\text{H}_{24}(\text{O})_2(\text{OMe})_4(\text{NMe})_2$  is proposed for (I).

CH. ABS. (r)

#### Alkaloids of *Sinomenium* and *Cocculus*. XLV. Stereochemical and biogenetic relationships of biscoclaurine alkaloids.

H. KONDO and M. TOMITA (Arch. Pharm., 1936, 274, 65—82).—The following alkaloids are considered to be derived from 2 mols. of coclaurine [7-hydroxy-6-methoxy-1-*p*-hydroxybenzyl-1:2:3:4-tetrahydroisoquinoline]: (a) oxidised to 2-methoxydiphenyl ether-5:4'-dicarboxylic acid (I): dauricine (II); oxyacanthine (III); berbamine; tetrandrine (IV) [optical isomeride of methylberbamine (=isotetrandrine)]; phæanthine [optical antipode of (IV)]; trilobamine; trilobine (V); isotrilobine (VI); menisarine (VII); normenisarine; cepharanthine; (b) not oxidised to (I): isochondodendrine (VIII); *l*-curine and its optical antipode *d*-bebeerine; insularine, probably  $\text{C}_{32}\text{H}_{23}(\text{O})_3(\text{OMe})_3(\text{NMe})_2$ , and not  $\text{C}_{19}\text{H}_{21}\text{O}_3\text{N}$  as previously suggested (J. Pharm. Soc. Japan, 1927, 47, 815). Constitutional formulæ (and, in some cases, models) are given; those previously suggested (A., 1932, 1048) for (V) and (VI) are modified. Possible biological syntheses of (II), (III), (V), (VII), and (VIII) are discussed. The botanical sources of the alkaloids are given.

H. B.

**Constitution of matrine.** XVIII. K. TSUDA (Ber., 1936, 69, [B], 429—434; cf. A., 1935, 1514).—The constitutions assigned (*loc. cit.*) to dihydro-(I) and dehydro- $\alpha$ -matrinidine (II) lead to the conclusion that acetyl- $\alpha$ -matrinidine is a  $\delta$ -NHAc-ketone; this is confirmed by the isolation of its *semicarbazone*,  $\text{C}_{15}\text{H}_{27}\text{O}_2\text{N}_5$ , decomp. 203°. Treatment of (II) in  $\text{C}_6\text{H}_6$  with LiBu followed by EtBr gives *decarboxydehydromatrinane* (III), b.p. 200—210°/4 mm. (*hydriodide*, m.p. 193—194.5°), identical

with one of the products of the dehydrogenation of matrine by Pd-asbestos (A., 1935, 766). The chemical

behaviour of (I) and its relationship to the known leguminous alkaloids indicate for it the constitution (I). Against this view, (II) is not converted into its  $\text{NH}_2$ -derivative by  $\text{NaNH}_2$ , and its Bu compound is not formed from (III) and LiBu in  $\text{C}_6\text{H}_6$  at 100°. (Conyryne and LiBu in  $\text{C}_6\text{H}_6$  afford 2-propyl-6-butylpyridine, b.p. 228—230°.) Successive treatment of Me methylmatrate methiodide with  $\text{Ag}_2\text{O}$  and  $\text{KMnO}_4$  gives  $\text{H}_2\text{C}_2\text{O}_4$ ,  $(\text{CH}_2\text{CO}_2\text{H})_2$ , and glutaric acid but no  $\text{AcCO}_2\text{H}$ . A 3-methylpyrrolidone ring cannot therefore be present in matrine, and the only remaining possibility is a pyrrolidone ring, thus leading to a choice of constitutions (A) or (B) for the alkaloid.

H. W.

**South American curare.**—See this vol., 534.

**Alkaloids.** R. ROBINSON (Ann. Rev. Biochem., 1935, 4, 497—518).—A review of the lit. for 1933—1934.

CH. ABS. (r)

**Decomposition of aromatic arsines in the Friedel and Crafts reaction.** M. S. MALINOVSKI (J. Gen. Chem. Russ., 1935, 5, 1355—1358).—Aromatic arsines yield  $\text{AsCl}_3$  and  $\text{COPhMe}$  or its derivatives when treated with  $\text{AcCl}$  or  $\text{CH}_2\text{Cl}\cdot\text{COCl}$  in presence of  $\text{AlCl}_3$ . The reaction is useful in the identification and elucidation of the structure of arsines.

R. T.

**Arsenic-containing azo-dyes from 4-aminodiphenyl-4'-arsinic acid.** G. I. GERSCHON and R. P. LASTOVSKI (J. Appl. Chem. Russ., 1935, 8, 1435—1438).—4-Acetamido-4'-diazodiphenyl sulphate in aq. EtOH and  $\text{AsCl}_3$  at 100° in presence of  $\text{CuCl}$  yield 4-aminodiphenyl-4'-arsinic acid, the diazo-derivative of which yields a red-brown product with  $\beta$ - $\text{C}_{10}\text{H}_7\cdot\text{OH}$ , and a violet dye with  $\text{H-acid}$ .

R. T.

**Phenylarsinic acid.** R. H. BULLARD and J. B. DICKEY (Org. Syntheses, 1935, 15, 59—61).—An improved prep. from  $\text{PhN}_2\text{Cl}$ ,  $\text{Na}_3\text{AsO}_3$ , and  $\text{CuSO}_4$  is described.

CH. ABS. (r)

**Mol. wts. of organoboric acids.** C. R. KINNEY and D. F. PONTZ (J. Amer. Chem. Soc., 1936, 58, 196).— $\text{ArB(OH)}_2$  ( $\text{Ar}=\text{Ph}$ , *p*- $\text{C}_6\text{H}_4\text{Me}$ , *m*- and *p*- $\text{C}_6\text{H}_4\text{Cl}$ , *p*- $\text{C}_6\text{H}_4\text{Br}$ , *o*- $\text{OEt-C}_6\text{H}_4$ , *p*- $\text{OPh-C}_6\text{H}_4$ , and  $\alpha$ - $\text{C}_{10}\text{H}_7$ ) are unimol. in  $\text{PhNO}_2$  (f.p. method).

H. B.

**Structure of organoboron oxides.** C. R. KINNEY and D. F. PONTZ (J. Amer. Chem. Soc., 1936, 58, 197).—The mol. wts. of phenyl-, *p*-tolyl-, *m*- and *p*-chlorophenyl-, *p*-bromophenyl-, and  $\alpha$ -naphthyl-boric oxides show considerable variation

in  $\text{PhNO}_2$  (f.-p. method) and indicate that the oxides are probably mixtures of  $\text{ArB} \begin{smallmatrix} \text{O} \\ \diagup \quad \diagdown \end{smallmatrix} \text{O} \text{Ar}$  and  $\text{O} \begin{smallmatrix} \text{Ar-O} \\ \diagup \quad \diagdown \end{smallmatrix} \text{O} \text{Ar}$ .

H. B.

**Relative reactivities of organometallic compounds. VI. Boron.** H. GILMAN and K. E. MARPLE. **VII. Calcium.** H. GILMAN, R. H. KIRBY, M. LICHTENWALTER, and R. V. YOUNG (Rec. trav. chim., 1936, 55, 76—79, 79—81).—VI. B has the function of a metal in organoboron compounds, but these are less reactive than true organometallic compounds.  $\text{BPh}_3$  with  $\text{PhCHO}$  and  $\text{PhNCO}$  yields respectively  $\text{CHPh}_2\text{OH}$  and  $\text{NHBzPh}$ . The colour test (cf. A., 1925, ii, 1011) is given more rapidly by  $\text{BPr}_3$  than by  $\text{BPh}_3$ , but less rapidly than by organoaluminium compounds.

**VII.** Contrary to Gilman and Schulze (A., 1926, 1130)  $\text{CaPhI}$  is more reactive than  $\text{MgPhI}$ , as it converts  $\text{PhCN}$  into  $\text{COPh}_2$  5 times as rapidly, converts diphenylene oxide into its -1-carboxylic acid ( $\text{MgPhI}$  does not), and converts  $\text{NPh:CPh}_2$  into  $\text{NHPPh:CPh}_2$  (analogy with  $\text{LiPh}$ ). F. R. G.

**Mercuration of nipasol, a propyl ester of p-hydroxybenzoic acid.** A. M. SAMSON and A. C. SANTOS (Univ. Philippines Nat. Appl. Sci. Bull., 1935, 4, 149—154).— $p\text{-OH}\cdot\text{C}_6\text{H}_4\cdot\text{CO}_2\text{Pr}$  with  $\text{Hg}(\text{OAc})_2$  in  $\text{AcOH-EtOH}$  affords a mixture (I) of  $\text{Pr } 3:5\text{-bis}(\text{acetoxymercuri})\text{-}$  and  $3\text{-(acetoxymercuri)-}4\text{-hydroxybenzoates}$ . (I) with  $\text{I-KI}$  yields a product of indefinite m.p., which affords  $3:5\text{-di-iodo-}$ , m.p. 236—237° (Me ester, m.p. 166—167°; Et ester, m.p. 123—124°), and  $3\text{-iodo-}$ , m.p. 190—200° (Me ester, m.p. 156—157°),  $4\text{-hydroxybenzoic acids}$  on hydrolysis with  $\text{EtOH-KOH}$ ; with  $\text{Br}$  (I) similarly affords  $3:5\text{-dibromo-}$ , m.p. 266—267° (Me ester, m.p. 125—126°), and  $3\text{-bromo-}$  (Me ester, m.p. 106—107°),  $4\text{-hydroxybenzoic acids}$ . CH. ABS. (r)

**Stereochemistry of some new complex thio-salts of mercury, cadmium, and zinc.** W. H. MILLS and R. E. D. CLARK (J.C.S., 1936, 175—181).— $1:3:4\text{-C}_6\text{H}_3\text{Me}(\text{SO}_2\text{Cl})_2$  is reduced ( $\text{Sn-HCl}$ ) to the  $3:4\text{-dithiol}$  (I), b.p.  $174^\circ/41\text{ mm.}$ , m.p.  $35^\circ$ .  $p\text{-C}_6\text{H}_4\text{Cl-NHAc}$  heated with conc.  $\text{H}_2\text{SO}_4$  affords  $p\text{-chloroanilinesulphonic acid}$ , converted through the diazonium xanthate and oxidation ( $\text{HNO}_3$ ,  $d$  1.4) into the  $3:4\text{-disulphonic acid}$  (Ba and Na salts), the sulphonyl chloride, m.p.  $82\text{--}83^\circ$ , of which is reduced to  $1\text{-chlorobenzene-}3:4\text{-dithiol}$  (II), b.p.  $165^\circ/32.5\text{ mm.}$ , m.p.  $31^\circ$ . When refluxed with yellow  $\text{HgO}$ , (I) in  $\text{KOEt-EtOH}$  affords  $\text{K}_2\text{ bis}(\text{toluene-}3:4\text{-dithiol})\text{-mercury}$ , +  $\text{EtOH}$  and solvent-free, of type  $[\text{Ar} \begin{smallmatrix} \text{S} \\ \diagup \quad \diagdown \end{smallmatrix} \text{M}' \begin{smallmatrix} \text{S} \\ \diagup \quad \diagdown \end{smallmatrix} \text{Ar}] \text{M}'_2$  (III) ( $\text{M}' = \text{Hg}$ ,  $\text{M}' = \text{K}$ ); similar complexes are obtained with Cd and Zn. The corresponding alkaloid salts ( $\text{M}' = \text{alkaloid}$ , H) are obtained (i) from the  $\text{K}_2$  salt and the base sulphate or hydrochloride in  $\text{EtOH}$ , or (ii) by the action of  $\text{HgO}$  on a solution of the base and thiol in  $\text{CHCl}_3$ . Thus, from (II) is obtained *diquinine*  $\text{H}_2\text{ bis}(\text{1-chlorobenzene-}3:4\text{-dithiol})\text{mercury}$  as its  $\alpha\text{-form}$ , m.p.  $142^\circ$ ,  $[\alpha]_{\text{D}}^{20} +182^\circ$  in  $\text{COMe}_2$ ,  $[\alpha]_{\text{D}}^{20} -191^\circ$  in  $1:1\text{ CHCl}_3\text{-COMe}_2$ , which dissolves readily in  $\text{COMe}_2$ , the solution depositing crystals of the  $\beta\text{-form}$ , m.p.  $138^\circ$ ,  $[\alpha]_{\text{D}}^{17} -240^\circ$

in  $\text{CHCl}_3$ ,  $[\alpha]_{\text{D}}^{20} -188^\circ$  in  $1:1\text{ CHCl}_3\text{-COMe}_2$ . The solution of the  $\beta\text{-form}$  in cold  $\text{CHCl}_3$  sets to a jelly which slowly crystallises at  $40\text{--}60^\circ$  to the  $\alpha\text{-form}$ . Interconversion of  $\alpha\text{-}$  and  $\beta\text{-forms}$  can be repeated indefinitely by such methods, using various solvents. Assuming a tetrahedral arrangement of the 4 S in the complex anion, resolution should be possible, but, probably owing to very rapid autoracemisation, the  $\text{Na}_2$  salts were inactive and showed no mutarotation even at  $-35^\circ$ . One form is probably of type (III) and the other is assigned a 3 co-ordinated Hg structure. By similar methods are obtained the  $\alpha\text{-}$ , + $\alpha\text{CHCl}_3$  (effloresces), and  $\beta\text{-}$ , m.p.  $157^\circ$ , forms of *diquinine*  $\text{H}_2\text{ bis}(\text{1-chlorobenzene-}3:4\text{-dithiol})\text{cadmium}$  and, from (I), the  $\alpha\text{-}$ , m.p.  $155^\circ$ , and  $\beta\text{-}$ , sinters  $128^\circ$ , m.p.  $145^\circ$ , forms of *diquinine*  $\text{H}_2\text{ bis}(\text{toluene-}3:4\text{-dithiol})\text{zinc}$ , similarly interconvertible. An apparatus for rapid low-temp. polarimetry is described. J. W. B.

**Organic thallium compounds. III. Synthesis of organic thallium compounds with simple substituents in the aromatic radical.** S. S. NAMETKIN, N. N. MELNIKOV, and G. P. GRATSHEV (J. Gen. Chem. Russ., 1935, 5, 1455—1459).—The following substituted aryl Tl halides have been prepared by the reactions:  $\text{RB(OH)}_2$  (I) +  $\text{TlX}_3 + \text{H}_2\text{O} \rightarrow \text{RTlX}_2$  (II) +  $\text{HX} + \text{H}_3\text{BO}_3$ ; (I) + (II) +  $\text{H}_2\text{O} \rightarrow \text{R}_2\text{TlX} + \text{HX} + \text{H}_3\text{BO}_3$ :  $p\text{-C}_6\text{H}_4\text{Br-TlCl}_2$ , m.p.  $262^\circ$  (decomp.);  $p\text{-C}_6\text{H}_4\text{Br-TlBr}_2$ , decomp. at  $190\text{--}200^\circ$ ;  $p\text{-C}_6\text{H}_4\text{Cl-TlCl}_2$ , m.p.  $>250^\circ$ ;  $p\text{-C}_6\text{H}_4\text{Cl-TlBr}_2$ , m.p.  $>250^\circ$ ;  $\text{CH}_2\text{Ph-TlBr}_2$ , m.p.  $205^\circ$  (decomp.);  $(p\text{-C}_6\text{H}_4\text{Br})_2\text{TlCl}$ , m.p.  $>250^\circ$ ;  $(p\text{-C}_6\text{H}_4\text{Br})_2\text{TlBr}$ , m.p.  $>250^\circ$ ;  $(p\text{-OMe-C}_6\text{H}_4)_2\text{TlBr}$ , m.p.  $>250^\circ$ ;  $(p\text{-C}_6\text{H}_4\text{Cl})_2\text{TlCl}$ , m.p. not given;  $(p\text{-C}_6\text{H}_4\text{Cl})_2\text{TlBr}$ , decomp. at  $240^\circ$ . R. T.

**Proteins in liquid ammonia. III. Reaction of sodium in liquid ammonia with proteins and related substances.** R. G. ROBERTS and C. O. MILLER (J. Amer. Chem. Soc., 1936, 58, 309—310; cf. A., 1934, 638).—Dry proteins react with Na in liquid  $\text{NH}_3$  as acids,  $\text{H}_2$  being evolved; reaction is much slower than with  $\text{NH}_2\text{-acids}$  or dipeptides. Using a slight excess of Na, the vals. of the ratio mols.  $\text{H}_2$  evolved to g.-atoms N present for caseinogen, edestin, gelatin, and zein are 0.215, 0.285, 0.35, and 0.09, respectively; these vals. are generally  $>$  those calc. from the glutamic, aspartic, and hydroxyglutamic acid content. H. B.

**Physical chemistry of zein.** C. C. WATSON, S. ARRHENIUS, and J. W. WILLIAMS (Nature, 1936, 137, 322—323).—By the addition of  $\text{H}_2\text{O}$  to the  $\text{EtOH}$  solution, purified zein can be divided into 3 practically homogeneous fractions, which are now characterised by their sedimentation, diffusion, and dielectric consts., and by their electrophoretic mobilities. L. S. T.

**Crystalline ovalbumin. III. Fractionation of peptic hydrolysis products by dialysis.** H. O. CALVERY and E. D. SCHOCK. **IV. Rate of liberation of amino-nitrogen and cystine, tyrosine, and tryptophan.** Colorigenic values during peptic, acid, and alkaline hydrolysis of ovalbumin. H. O. CALVERY, W. D. BLOCK, and E. D. SCHOCK (J. Biol. Chem., 1936, 113, 15—19, 21—25).—III. Dialysis can be used to separate

peptic hydrolysis products into fractions of different composition. Free tyrosine has been isolated from a peptic hydrolysate of cryst. ovalbumin, thus supporting the view that free  $\text{NH}_2$ -acids are liberated when pepsin acts on protein.

IV. Uncoagulated cryst. ovalbumin is readily hydrolysed when the pepsin to protein ratio is 1:10 and the acid concn. is approx. 0.3%. During the digestion the  $\text{NH}_2\text{-N}$  val. rises gradually to a max. of 25.1% in 36 days whilst the chromogenic val. obtained by the Folin-Marenzi method for cystine increases gradually to a max. of 2.1% within 12 hr. and then falls to a const. val. between 1.6 and 1.7% during the next 35 days. This is much > the highest val. (1.3%) obtained by acid hydrolysis. The acid peak was reached after a gradual rise and did not follow the same curve as that obtained by Jones *et al.* (A., 1933, 1081) for the cystine content of caseinogen. The tyrosine and tryptophan colorogenic vals. rose gradually until they reached a max. during peptic and alkaline hydrolysis; the max. are not coincident.

H. W.

Dilatometric investigations on the heat-denaturation of proteins. I. E. HEYMANN (Biochem. J., 1936, 30, 127—131).—Solutions of serum-albumin and -globulin, ovalbumin, and zein all showed an increase in total vol. on heat-denaturation; when the latter was not accompanied by coagulation the vol. changes were smaller. The vol. increases were only 3—4% of the vol. decreases on dissolving in  $\text{H}_2\text{O}$ . A sensitive dilatometer is described.

H. D.

Chemistry of heat-denaturation of proteins. A. KIESEL and S. KUSMIN (Z. physiol. Chem., 1936, 238, 145—148).—The denaturation by heat ( $60^\circ$ ) of edestin (I) is accompanied by increases in the tyrosine and histidine (II) contents. Possibly ring-closure is the cause of the (II) increase. Elimination of  $\text{H}_2\text{O}$  occurs on methylation of (I), but not in denaturation by heat.

W. McC.

Ultrafiltration of proteins. II.—See this vol., 500.

Relation of protein coagulation to oxidation-reduction potential.—See this vol., 360.

Ionic structure solubility, and coagulation of proteins.—See this vol., 426.

Nitrogen determination by ter Meulen's method. P. MAES (Bull. Assoc. anc. Elèves Gand, 1935, 36, 39—41; Chem. Zentr., 1935, i, 3821).—A modified method is described.

H. N. R.

Determination of small amounts of arsenic in organic compounds. K. WINTERFELD, E. DÖRLE, and C. RAUCH (Arch. Pharm., 1936, 274, 214).—A correction (cf. this vol., 90).

Determination of methoxyl and ethoxyl groups. C. L. PALFRAY (Documentat. sci., 1935, 4, 1—3; Chem. Zentr., 1935, i, 3821).—A volumetric Zeisel method is described.

H. N. R.

Determination of semicarbazide and semicarbazones. V. HARLAY (J. Pharm. Chim., 1936,

L L

[viii], 23, 199—204).—Passage of steam for 8—10 hr. through a solution of semicarbazones in 20%  $\text{H}_2\text{SO}_4$  liberates semicarbazide which is decomposed to  $\text{N}_2\text{H}_4$ ; this is determined by I in AcOH solution. The method is applicable to semicarbazide and semicarbazones of aldehydes and ketones, but not to those of ketonic acids.

R. S. C.

Determination of carotene and xanthophyll by a single distribution between liquid phases. S. W. CLAUSEN and A. B. MCCOORD (J. Biol. Chem., 1936, 113, 89—104).—A general colorimetric method for the determination of two substances of the same colour by a single distribution between two immiscible liquids is described, and applied to mixtures of carotene and xanthophyll using hexane and aq. diacetone alcohol. The method is applicable to pigments in plasma and serum.

J. N. A.

Ehrlich diazo-reaction with urine.—See this vol., 502.

Decomposition of salts of acetylsalicylic acid. V. GERVAY (Magyar gyóg. Társ. Ért., 1935, 11, 241—245; Chem. Zentr., 1935, ii, 250).—Owing to this decomp. the determination of free salicylic acid can only be approx.

H. N. R.

Colour reaction of ammonia and glycine with hypobromite and phenolic substances. O. FÜRTH and F. GÖTZL (Biochem. Z., 1936, 283, 358—363).—The elementary compositions of a series of blue pigments obtained by interaction of  $\text{NaOBr}$  with  $\text{PhOH}$  (or thymol) and  $\text{NH}_2$ -acids (or  $\text{NH}_4$  salts) are summarised in the formula  $\text{C}_{15-84}\text{H}_{45-113}\text{NBr}_{1-5-3}$ .

P. W. C.

Determination of phytic acid.—See this vol., 535.

Gross and Smith colorimetric method for determination of rotenone and deguelin. L. D. GOODHUE (J. Assoc. Off. Agric. Chem., 1936, 19, 118—120; cf. A., 1934, 1017).— $\text{H}_2\text{SO}_4$  is substituted for  $\text{HNO}_3$ , the  $\text{KOH}$  in  $\text{EtOH}$  is diluted with  $\text{H}_2\text{O}$ , and the necessary  $\text{NO}_2$  added as  $\text{NaNO}_2$  to this solution. Fading is eliminated and the sensitivity increased 20-fold.

E. C. S.

Identification of alkaloids as picrates. A. IONESCO-MATIU and E. ILIESCO (J. Pharm. Chim., 1936, [viii], 23, 117—141).—Microchemical identification of alkaloids as picrates using (a) a cold saturated solution of picric acid (I) in 96%  $\text{EtOH}$  containing 5% of glycerol, or (b) picramic acid obtained by reduction of a 5% aq. solution of (I) with  $\text{Na}_2\text{CO}_3$ -glucose, is described. Using one drop of the alkaloid solution the picrates of the following are described, the sensitivity of the reaction, in mg. unless otherwise stated, being given in parentheses: atropine, m.p.  $165\text{—}166^\circ$  (b,  $10^{-2}$ ), hyoscyamine, m.p.  $162\text{—}163^\circ$  (a, 0.5), nicotine, darkens  $200^\circ$ , m.p.  $208^\circ$  (a,  $10^{-3}$ ), strychnine, decomp.  $200^\circ$  (a,  $2 \times 10^{-3}$ ; b,  $2 \times 10^{-4}$ ), brucine (a,  $5 \times 10^{-2}$ ), morphine (a, 0.5% solution), codeine (a, 0.2% solution), dionine (a, 0.1% solution), heroin (a, 0.01% solution), papaverine, shrinks  $150^\circ$ , m.p.  $154^\circ$  (a,  $10^{-2}$ ), sparteine, darkens  $195\text{—}196^\circ$ , m.p.  $199^\circ$  (a, 0.05), hydrastinine (a, 0.08% solution), cocaine, m.p.  $154\text{—}155^\circ$  (b,  $2 \times 10^{-3}$ ), ephedrine (a, > 0.8% solution), novo-

caine, reddens  $140^{\circ}$ , m.p.  $146-147^{\circ}$  ( $\alpha$ , 0.4% solution), stovaine, m.p.  $110-112^{\circ}$  ( $\alpha$ , 0.02%), antipyrine, m.p.  $180-182^{\circ}$  ( $\alpha$ ,  $10^{-2}$ ), and pyramidone, m.p.  $168-170^{\circ}$  ( $\alpha$ , 0.04% solution). Photomicrographs are given in each case. J. W. B.

**Recognition of papaverines by a colour reaction with acetic anhydride and sulphuric acid.** W. AWE (Pharm. Zentr., 1936, 77, 157-160; cf. A., 1923, i, 701).—Papaverine (5 mg.) in  $\text{Ac}_2\text{O}$  (3 c.c.) containing  $\text{H}_2\text{SO}_4$  (5 drops) at  $80^{\circ}$  affords a solution with a yellowish-green fluorescence in daylight. 0.05 mg. can be recognised by observing the fluorescence in ultra-violet light. When  $\text{AcCl-ZnCl}_2$  is used as condensing agent, the fluorescence in daylight is

obscured by the colour of the solution. Cryptopine (A., 1910, i, 502) does not interfere. J. L. D.

**Use of Zimmermann's reagent for detection of glycine and for determining its position in polypeptides.** E. ABDERHALDEN and A. NEUMANN (Z. physiol. Chem., 1936, 238, 177-182; cf. A., 1930, 897).—When free glycine (I) is present a ppt. is always produced. Of the other  $\text{NH}_2$ -acids (not mentioned by Zimmermann) of the protein mol. only tryptophan (which gives a brown ppt. and green solution) interferes. With polypeptides containing the (I) residue the reaction is positive only when this residue carries the  $\text{NH}_2$  (negative with silk fibroin, positive with silk peptone). W. McC.

## Biochemistry.

**Biochemistry and biophysics.** P. L. DU NOÛY (Bull. Soc. Chim. biol., 1936, 18, 138-156).—A lecture.

**Response of the chemical receptors of the carotid sinuses to the tension of carbon dioxide in the arterial blood in the cat.** A. SAMAAH and G. STELLA (J. Physiol., 1935, 85, 309-319).

R. N. C.

**Retention of carbonic acid in the dormouse (*Myoxus glis*) in course of carbon dioxide narcosis and rôle of the tissues in the maintenance of the alkaline reserve.** L. DONTCHEFF and C. KAYSER (Compt. rend. Soc. Biol., 1936, 121, 447-449).—The anaesthetised animal retains considerable quantities of  $\text{CO}_2$ , suggesting the presence of an "alkaline reserve" in the tissues equiv. to that of the blood.

R. N. C.

**Nitrogen solubility in blood at increased air pressures.** J. A. HAWKINS and C. W. SHILLING (J. Biol. Chem., 1936, 113, 273-278).—The solubility coeff. of  $\text{N}_2$  (at atm. pressure) in dog's and ox blood is 0.0138-0.0148 and 0.0135-0.0140, respectively. With pressures of  $\text{N}_2$  of 1-6 atm., the val. follows Henry's law.

H. G. R.

**Regulation of the oxygen output of erythrocytes.** I. F. HIMMERICH. II. **Blood-glycolysis.** F. HIMMERICH and R. S. FEINBERG (Biochem. Z., 1936, 284, 146-151, 152-162).—I. An apparatus for measuring the output is described.

II. The glycolysis resulting from addition of glucose to human erythrocytes increases (up to 200%) their  $\text{O}_2$  output. Similarly, in defibrinated human and rabbits' blood the increased glycolysis due to an increase of 0.25-0.3 in  $p_{\text{H}}$  results in increases (up to > 300%) in the  $\text{O}_2$  output. Apparently all factors which stimulate glycolysis increase  $\text{O}_2$  output. Probably the glycolysis occurs at the surface of the erythrocytes and the accompanying production of acid and liberation of heat may play important parts in the process.

W. McC.

**Determination of colloid-osmotic pressure.** H. NAGAOKA (J. Biochem. Japan, 1935, 22, 351-366).—The colloid-osmotic pressure of horse serum, measured by a collodion membrane with a standard

membrane potential of 2-5 mv., attains equilibrium after 24 hr.; comparative measurements can be taken after 3-24 hr. Relationships between the pressure and concn. of colloid and temp. are determined.

F. O. H.

**Electrodialysis of serum.** A. V. MARKOVITSCH (J. Appl. Chem. Russ., 1935, 8, 1444-1451).—The  $p_{\text{H}}$  of serum falls during electrodialysis (parchment cathode and bakelite-paper anode membranes) from the original val. to 5.2. Max. pptn. of globulins takes place at  $p_{\text{H}}$  5.6-5.7, at low concn. of electrolytes.

R. T.

**Effect of continued passage of current through the external medium on the composition of blood in *Scyllium canicula*, the bronchial region being near the cathode.** E. A. PORA (Compt. rend. Soc. Biol., 1936, 121, 411-413).—The osmotic pressure and corpuscular vol. increase with the intensity of the current. Ca and proteins also increase, whilst K and alkaline reserve decrease progressively. Vals. afterwards tend to return to normal. Serum- $\text{H}_2\text{O}$  falls, but inorg. salts and org. substances both increase at the expense of the muscles, which take up  $\text{H}_2\text{O}$ .

R. N. C.

**Modifications of the blood of *Perca fluviatilis*, consecutive to deep-sea fishing.** L. BAUDIN (Compt. rend. Soc. Biol., 1936, 121, 437-439).

R. N. C.

**Determination of the alkaline reserve in small mammals.** L. DONTCHEFF and C. KAYSER (Compt. rend. Soc. Biol., 1936, 121, 446-447).—The Van Slyke const.-vol. apparatus is used. Local anaesthetisation during the drawing of blood is necessary.

R. N. C.

**Effect of physical training on blood-volume, hæmoglobin, alkaline reserve, and osmotic resistance of erythrocytes.** J. E. DAVIS and N. BREWER (Amer. J. Physiol., 1935, 113, 586-591).—Blood-vol. and hæmoglobin per unit vol. (I) in the dog fall during the first week of training, and later rise, but (I) is never > normal. The alkaline reserve is increased. Erythrocyte osmotic resistance rises in swimming but falls in running animals.

R. N. C.

**Analysis of the constituents of suspensions of erythrocytes by the method of neutralisation**

curves. G. ACHARD (Compt. rend. Soc. Biol., 1936, 121, 478—481).—The buffering effect of erythrocyte suspensions, their excipients, and laked erythrocyte solutions is due to factors other than the inorg. salts present. R. N. C.

Alteration, with time, of the buffering power of suspensions of erythrocytes. G. ACHARD (Compt. rend. Soc. Biol., 1936, 121, 481—484).—After prolonged action of acids or alkalis on erythrocyte suspensions the neutralisation curves resemble those obtained in suspensions laked with  $H_2O$ . R. N. C.

Reduction of oxyhæmoglobin in the human skin. L. NICOLAI (Pflüger's Archiv, 1932, 230, 238—245; cf. A., 1932, 1270).—Reduction of oxyhæmoglobin in the skin follows the equation  $c=c_0e^{-kt}$ . The rate of reduction is unchanged in hyperæmia following anoxæmia. R. N. C.

Fate of hæmoglobin in the organism. K. BINGOLD (Klin. Woch., 1934, 13, 1451—1452).—A pigment (I) with a band at 535  $m\mu$  is formed by the action of alkaline  $Na_2S_2O_4$  on bilirubin-rich urine. It is found in old pleural exudates, but not in serum; its appearance in the urine is unaltered if the liver is choked. (I) is considered to be free from Fe and not bound to proteins, the colour being due to formation of a S derivative. Pigeons' blood or hæmin decolorised with  $H_2O_2$  and boiled with KOH gives a band at 535  $m\mu$ ;  $Na_2S_2O_4$  is often necessary for production of the spectrum. Cultures of *Pneumococci* on catalase-free blood-agar break down the blood to (I). R. N. C.

Effect of diet on the hæmoglobin concentration of the blood. L. N. ELLIS and O. A. BESSEY (Amer. J. Physiol., 1935, 113, 582—585).—Hæmoglobin in the rat at 1 month  $\propto$  the Fe content of the diet, but is independent at 1 year, when it falls into one of two ranges of vals., according to the sp. diet given. R. N. C.

Occurrence of several kinds of hæmoglobin in human blood. R. BRINKMAN and J. H. P. JONXIS (J. Physiol., 1935, 85, 117—127).—Fœtal hæmoglobin is replaced by a "less resistant" adult hæmoglobin after 7 months, and this in turn is replaced after 3 years by a hæmoglobin more resistant to alkaline denaturation. The three hæmoglobins differ in rate of alkaline denaturation and in isoelectric point, and so far have been detected only in human blood. R. N. C.

Relationship between specific gravity and protein content in plasma, serum, and transudate from dogs. A. A. WEECH, E. B. REEVES, and E. GOETTSCH (J. Biol. Chem., 1936, 113, 167—174).—The  $d$  of blood-plasma, -serum, or -transudate  $\propto$  the protein concn. H. D.

Serum electrolytes. X. Water of serum and factors for calculation of molality of a solute in serum from measurement of specific gravity. F. W. SUNDERMAN (J. Biol. Chem., 1936, 113, 111—115).—The  $d$  of serum bears to the total solids a linear relation (consts. given) from which concns. of a solid related to  $[H_2O]$  may be obtained. F. A. A.

Conductometric method for investigation of colloidal suspensions. A. SLAVINSKI (Bull. Soc. Chim. biol., 1936, 18, 195—202).—The author's method (A., 1934, 860) for determining the vol. of colloidal particles is applied to blood-plasma. Human and horse plasma contain about 9% of albumin associated with 4.5% of liquid, the tonicity of the plasma being that of 0.85% aq. NaCl. Measurements with hæmolyzed blood indicate that the corpuscles contain "hæmoglobules" occupying 55% of the vol. of the corpuscles and containing 52% of hæmoglobin and 48% of liquid. A. L.

Effect of hæmorrhage of varying degree on blood and plasma volume, on blood-sugar, and on arterial blood pressure. J. D. ROBERTSON (J. Physiol., 1935, 84, 393—409). R. N. C.

Effect of splenic extracts on the blood picture. T. IMAI (Tohoku J. Exp. Med., 1933, 22, 293—313). CH. ABS. (p)

Cyclic variations in the composition of fish blood. L. BAUDIN (Compt. rend. Soc. Biol., 1936, 121, 501—502). R. N. C.

Ultrafiltration studies with normal horse serum. W. J. ELFORD, P. GRABAR, and W. FISCHER (Biochem. J., 1936, 30, 92—99).—Analysis of the state of aggregation of horse serum-proteins by ultrafiltration through graded collodion membranes shows that the simplest protein units correspond in particle size with mol. serum-albumin (I) and pseudoglobulin in dil. solutions, and that a second fraction is present which is more readily retained by membranes and in particle size about twice that of (I). This fraction is essentially a globulin (II) aggregate and may correspond with the euglobulin of serum. The antibody of an aged sample of type I pneumococcus antiserum was retained by membranes simultaneously with the more complex (II) fraction. P. W. C.

Activity of the globulins of blood as alexins. M. DOLADILHE (Compt. rend., 1935, 201, 689—690).—The globulins (I) pptd. from diluted serum with  $CO_2$  are sol. in saline and are then separated by  $CO_2$  into an insol. (0.2036% P) and a sol. (0.0782% P) fraction, which may be components of a sol. complex. The sol. fraction exhibits the central-group properties of alexin, of the same intensity as does the saline solution of (I). J. L. D.

Total plasma-protein in normal and fasting rats. W. C. CUTTING and R. D. CUTTER (Amer. J. Physiol., 1935, 113, 150—158).—Total plasma-protein (I) is measured by determination of the blood vol. (for which a method is described) and protein concn. Decrease of (I) during fasting  $\propto$  time. Lymph- and plasma-proteins resemble each other in composition and participation in body functions. R. N. C.

Tyramine as a pressor substance in pallid hypertension. H. A. HEINSEN and H. J. WOLF (Klin. Woch., 1934, 13, 1688).—Blood fractions obtained by extraction of the deproteinised blood with  $C_2H_5OH$  and  $H_2SO_4$  give the color reaction with 1:2- $NO \cdot C_{10}H_6 \cdot OH$  and  $HNO_3$ , suggesting that tyramine is a cause of pallid hypertension. R. N. C.

**Pharmacological determination of adenosine and histamine in blood.** G. S. BARSOUM and J. H. GADDUM (*J. Physiol.*, 1935, 85, 1—14).—Tests described can detect  $2 \times 10^{-8}$  g. of histamine (I) and  $0.5 \times 10^{-6}$  g. of adenosine (II). (I) is present in normal human, rabbit's, guinea-pig's, dog's, and probably cat's blood. Corpuscular (I) and (II) are  $>$  plasma-(I) and -(II), respectively. Clotting of blood or shaking of citrated blood increases (II) without affecting (I). R. N. C.

**Appearance of histamine in venous blood during muscular contraction.** G. V. ANREP and G. S. BARSOUM (*J. Physiol.*, 1935, 85, 409—420).—The histamine (I) contents of the arterial and venous blood to and from resting muscle are the same. Venous (I) is increased by diminution of the blood supply and by muscular contraction. R. N. C.

**Presence of creatinine in blood.** I. S. DANIELSON (*J. Biol. Chem.*, 1936, 113, 181—195).—The major part of the chromogenic substance (in the Folin-Wu determination; A., 1919, ii, 308) in blood  $H_2WO_4$  filtrates and plasma ultra-filtrates is adsorbed by kaolin. The colour developed in a kaolin-treated filtrate heated with aq. NaOH is approx. the same as that obtained with an ordinary filtrate, whereas pure solutions of creatinine (I), or the material eluted from the kaolin, on treatment with NaOH give no colour with alkaline picrate. It is concluded that the chromogenic material in blood filtrates is (I). H. D.

**Variations of concentration of conjugated phenols in blood in passing different organs.** A. D. MARENZI (*An. Farm. Biochim.*, 1933, 4, 36—38; *Chem. Zentr.*, 1935, i, 3562).—The conjugated phenol content of portal blood is  $>$  that of the carotid and vena cava inferior. R. N. C.

**Lipochromes of human blood-serum.** E. VON DANIEL and T. BÉRES (*Z. physiol. Chem.*, 1936, 238, 160—162).—The material obtained from 3 litres of the serum by chromatographic adsorption on  $Ca(OH)_2$  (after pptg. with  $EtOH$ , etc.) consisted of 0.33 mg. of a yellowish-brown pigment (absorption max. at 502.5 and 472  $m\mu$ ), 0.15 mg. of lycopen, 0.08 mg. of a light yellow pigment (max. at 455 and 425  $m\mu$ ), and 0.28 mg. of carotene. The unidentified pigments may be biologically active. The proportions in which the pigments occur in the serum and the amounts of the individual pigments vary greatly. W. McC.

**Determination of fat in 0.1 c.c. of blood or serum.** J. SURÁNYI and P. VÉGHÉLYI (*Biochem. Z.*, 1936, 283, 415—421).—Blood (0.05 c.c. in each case) was extracted with  $EtOH$  and  $COMe_2$  at 100° and 75° and the filtered extracts were treated with  $HCl-H_2O-BuOH$ . The resulting turbidities were measured by the step-photometer. The total fat was thus obtained in the  $EtOH$  extract whilst lecithin was absent from the  $COMe_2$  extract. P. W. C.

**Spectrophotometric determination of blood-cholesterol by means of silica.** H. FOY and A. KONDI (*Brit. J. Exp. Path.*, 1935, 16, 349—357).—Variations in the state of hydration of plaster of Paris render the Myers and Wardell method unsatis-

factory. A modified method replacing this by  $SiO_2$  and using a photometer is described.

NUTR. ABS. (m)

**Effect of glucose ingestion on the cholesterol fractions of blood.** F. FITZ and M. BRUGER (*J. Biol. Chem.*, 1936, 113, 297—302).—The increase in total cholesterol when glucose is fed to fasting subjects is located in the cholesteryl ester fraction. H. G. R.

**Physiology of blood-glycogen.** I. G. GOLANDAS. II. H. STAUB and G. GOLANDAS (*Pflüger's Archiv*, 1935, 236, 230—238, 355—360).—I. The mean val. for fasting blood-glycogen (I) in the dog is slightly  $>$  that in man or rabbits. Plasma- and serum-glycogen are the same for all three; the greater part of (I) is contained in the corpuscles. (I) does not vary in the same subject; it diminishes in sterile blood stored at 37°, is scarcely altered at —8°, and is increased in unsterilised blood at 37° by bacterial action.

II. (I) rises in dogs and rabbits after fasting for 144—170 hr. Overcharging with carbohydrate generally increases (I) in man (mainly in the corpuscles) and rabbits. R. N. C.

**Mechanism of the origin of alimentary hyperglycaemia.** Y. HUKUI (*J. Biochem. Japan*, 1935, 22, 447—496).—Direct application of glucose (I) to the duodenum of rabbits produces no significant hyperglycaemia. Direct administration of (I), galactose, or fructose to the stomach or duodenum does not change the sugar content curves of blood from the portal, hepatic, or ear veins. Splanchnicotomy and/or vagotomy lower the alimentary hyperglycaemic curve. Administration of ergotamine or atropine also lowers the curve. Oral administration of fructose produces a hyperglycaemia due to blood-(I) and reduced by splanchnicotomy. The data support the absorption rather than the reflex-mechanism theory. F. O. H.

**True blood-sugar level in insulin shock and convulsions.** L. B. DOTTI and M. C. HRUBETZ (*J. Biol. Chem.*, 1936, 113, 141—143; cf. A., 1934, 565).—In rats, the true blood-sugar level falls during the course of insulin shock, and at the onset of convulsions is zero. F. A. A.

**Variations of blood-sugar in rabbits following subcutaneous injections of phenylhydrazine hydrochloride.** P. DERVILLÉE, L. LANSAC-FATTE, and R. CASTAGNOU (*Compt. rend. Soc. Biol.*, 1936, 121, 549—552).—Hyperglycaemia occurs in varying degree, but no hypoglycaemia. R. N. C.

**Lactacidæmia in fowls with avitaminosis-B.** I. I. NITZESCU and I. GONTZEA (*Compt. rend. Soc. Biol.*, 1936, 121, 562—563). R. N. C.

**Influence of preliminary training on the lactic acid content of blood after intense work.** A. V. PALLADIN and B. M. KOLDAEV (*Ukrain Biochem. J.*, 1934, 7, No. 1, 30—39).—Intense work causes accumulation of lactic acid in blood. Preliminary training lowers the rate of accumulation. CH. ABS. (p)

**Mendel and Goldscheider's method for determining lactic acid in blood.** R. MILTON (*Analyst*,

1936, 61, 91—96; cf. A., 1926, 212).—The effect of temp., time of heating, and concn. of  $\text{H}_2\text{SO}_4$  and veratrole on the intensity of the colour produced is investigated and modifications are suggested. The results obtained are slightly lower, but more consistent, than those given by Friedemann and Kendall's method (A., 1929, 677).  
E. C. S.

**Determination of sodium formaldehyde-sulphoxylate in blood-plasma.** E. HUG (Compt. rend. Soc. Biol., 1936, 121, 577—579).—Plasma is deproteinised with  $\text{UO}_2(\text{OAc})_2$ , and  $\text{NaHSO}_2\cdot\text{CH}_2\text{O}$  determined with I.  
R. N. C.

**Partition of calcium and inorganic phosphorus in equine serum.** P. B. PEARSON and H. R. CATCHPOLE (Proc. Amer. Soc. Animal Prod., 1935, Jan., 84—86).—Average vals. for total Ca and P in horses on a diet with adequate Ca and P were  $13.13 \pm 1.03$  and  $3.37 \pm 0.29$  mg. per 100 ml., respectively, and on a low-P diet vals. were  $13.60 \pm 0.70$  and  $2.61 \pm 0.21$  mg. The vals. for diffusible Ca and P were  $7.15 \pm 0.87$  and  $3.02 \pm 0.32$  mg. for the former and  $8.09 \pm 0.84$  and  $2.47 \pm 0.29$  mg. for the latter.  
NUTR. ABS. (m)

**Composition of the blood of dairy cattle. I. Effect of age and phosphorus intake on calcium and inorganic phosphorus content of whole blood of dairy heifers.** A. H. VAN LANDINGHAM, H. O. HENDERSON, and G. A. BOWLING (J. Dairy Sci., 1935, 18, 557—572).—Feeding of P-deficient rations lowers the blood-inorg. P to extents approx.  $\propto$  the deficiency. The P requirement of growing animals is not  $\propto$  the increase in body-wt. but depends on skeletal development as measured by the height of the withers. The requirement in proportion to body-wt. decreases as the animal approaches maturity. Age and level of P intake were without effect on blood-Ca.  
A. G. P.

**Blood-calcium in newborn infants.** N. P. COSTA, F. ESCARDO, and S. SCHERE (Rev. Soc. Argentina biol., 1934, 10, 273—279).—In newborn infants blood-Ca was slightly  $<$  that of the mother.  
CH. ABS. (p)

**Blood-magnesium in pregnant women.** N. ZAHARESCO-KARAMAN, M. ALEXIU, and I. URSU (Compt. rend. Soc. Biol., 1936, 121, 559—561).—Blood-Mg rises steadily to a max. in the 5th month, falls sharply in the 6th, rises again to the approx. val. of the first max. in the 7th, and then falls slightly until the end of pregnancy.  
R. N. C.

**Iodometric determination of iron in blood.** LASAUSSE and L. FROCRAIN (J. Pharm. Chim., 1936, [viii], 23, 82—84).—Aq.  $\text{NH}_3$  and milk of  $\text{MgO}$  are added and, after evaporating to dryness, incinerating at low temp., and igniting, the residue is freed from  $\text{HNO}_3$  by  $\text{HCl}$ , dissolved in  $\text{HCl}$ , and mixed with aq.  $\text{KI}$ . After 3 min. 3 drops of amidone solution are added and liberated I is titrated with 0.005N- $\text{Na}_2\text{S}_2\text{O}_3$ .  
W. McC.

**Effect of adrenalectomy on blood-chloride and -sodium.** C. I. URECHIA, G. BENETATO, and RETEZEANU (Bull. Acad. Méd. Roumanie, 1936, 1, 141—144).—Adrenalectomy in cats produces

a rise or fall in blood-Cl, but generally a fall in -Na.  
F. O. H.

**Blood-bromine.** C. I. URECHIA and RETEZEANU (Presse méd., 1935, 43, 701—703).—Low blood-Br was found only in manic-depressive psychoses. Injection of drugs and therapeutic preps. did not reduce it.  
NUTR. ABS. (m)

**Blood-iodine. V. Blood-iodine after total thyroidectomy in man.** G. M. CURTIS, L. E. BARRON, and F. J. PHILLIPS (J. Lab. Clin. Med., 1935, 20, 813—816; cf. A., 1934, 1024).—Thyroidectomy is followed by a rapid transient increase and a subsequent decline in blood-I to  $<$  normal. I then present in blood is probably absorbed from the alimentary tract.  
CH. ABS. (p)

**Polysaccharide hydrogen sulphates with heparin-like action.**—See this vol., 453.

**Effects of sodium citrate on the alkaline reserve and coagulability of the blood.** D. DE SOUZA and F. D. M. HOCKING (J. Physiol., 1935, 85, 168—172).—Alkaline reserve is increased; coagulability is increased with small, and reduced by larger, doses.  
R. N. C.

**Changes in the coagulability of the blood produced by citric acid and some of its decomposition products.** D. DE SOUZA and F. D. M. HOCKING (J. Physiol., 1935, 85, 173—178).—Citric acid or  $\text{NH}_4$  citrate (intramuscular) increases alkaline reserve and coagulability of cats' blood. Acetonedicarboxylic and aconitic acids may increase or diminish coagulability without affecting alkaline reserve, but their Na salts increase both;  $\text{COMe}_2$  affects neither.  
R. N. C.

**Blood coagulation.** H. DYCKERHOFF and H. F. KÜRZEN (Biochem. Z., 1936, 284, 111—132).—Thrombin (I) contains a very small amount of firmly bound Ca. The Ca-free material has no coagulating power, but very rapidly unites with Ca to produce active (I). Circulating blood contains  $>$  sufficient Ca to meet the requirements of (I). Under normal conditions  $\text{Ca}^{++}$  has no effect on coagulation. Pre-formed (I) probably occurs in circulating blood. Thrombokinase (II) activates (I) by removing inhibitors, in the absence of which (I) causes coagulation when  $\text{Ca}^{++}$  and (II) are not present.  
W. McC.

**Influence of novocaine anaesthesia on the fibrinogen content of the plasma and its coagulation.** W. L. DULIÈRE, A. HUSTIN, and P. BOSSAERT (Bull. Soc. Chim. biol., 1936, 18, 234—236).—Lumbar injection of novocaine causes a decrease in hæmatocrit, time of coagulation, and concn. of fibrinogen, followed by gradual return to normal.  
A. L.

**Technique for determination of fibrinogen in human blood: rate of coagulation of plasma.** W. L. DULIÈRE (Bull. Soc. Chim. biol., 1936, 18, 231—233)

**Test for coprosterol in plasma.**—See this vol., 467.

**Effect of spleen extract on the time of coagulation, thrombocytes, and erythrocytes of the**

blood. E. HAENLEIN and E. SCHLIEPHAKE (Klin. Woch., 1935, 14, 79—83). R. N. C.

Preparation of cobra-toxin for clinical purposes, particularly for alleviation of cancer pain. L. W. VAN ESVELD (Biochem. Z., 1936, 283, 343—357).—A method is described for separating from cobra-toxin the hæmolysin, hæmorrhagin, and non-toxic albumin contents without any considerable loss of the sp. neurotoxin. The purified prep., kept in the dark at  $p_H$  5.2, remained completely active for months while in clinical use. P. W. C.

Chemistry of immunity reactions. IV. Distribution of chemically distinguished antigens in the organism of normal and sensitised animals. F. HAUROWITZ and F. KRAUS (Z. physiol. Chem., 1936, 239, 76—82; cf. A., 1932, 542; 1933, 411).—Injection of arsanilazoprotein (I) into normal guinea-pigs is followed by accumulation of As in the organs of the reticulo-endothelial system, particularly in the liver. Similar results are obtained after injection of a suitable antiserum (*loc. cit.*). The gradual degradation of (I) in the organism has been studied. After injection of iodoglobulin the main portion of the antigen is found in the liver. H. W.

Recovery and stabilisation of the antibacterial agglutinin and anti-sheep hæmolysin of serum. H. GOLDIE (Compt. rend. Soc. Biol., 1936, 121, 761—764).—The agglutinin of *B. coli* and anti-sheep hæmolysin are recovered from their respective complexes by stabilisation with  $CH_2O$  and pptn. with 1:4:6:8- $NH_2 \cdot C_{10}H_4(SO_3Na)_3$  and citric acid. Both show the variation of  $p_H$  and isoelectric point and increase of thermostability on storage, exhibited by antitoxin recovered by flocculation with the toxin, and are not affected by heating to 85°, which denatures the associated globulins and reduces their anaphylactic activity. R. N. C.

Favourable effect of some lipins on the immunising action of antigens. G. RAMON (Compt. rend., 1935, 201, 687—689).—Tetanus toxin in oil containing cholesterol (I) when injected subcutaneously into horses is at least 7500 times as active in producing antibodies as when (I) is omitted. J. L. D.

Specific antigen and antibody in the urine of pregnant women. L. GRIMARD (Compt. rend. Soc. Biol., 1936, 121, 743—746). R. N. C.

Keten, a new reagent for detoxification of vaccine. J. T. TAMURA and M. J. BOYD (Science, 1936, 83, 61—62).—Acetylation of *B. dysenteriae*, Shiga, with keten for 30 min. detoxifies the antigen. L. S. T.

Characters of antitoxins purified by flocculation, stabilised by formaldehyde, and recovered with sodium naphthylaminetrisulphonate. H. GOLDIE (Compt. rend. Soc. Biol., 1936, 121, 649—652).—The recovered antitoxins become progressively acid during the first 2—3 months of storage, the isoelectric point is shifted, and the thermo-resistance increases. The antigenic power is not affected, but the anaphylactic action is reduced by heating to 80—85° to denature the attacked globulins; the antitoxin is unaffected by such heating. R. N. C.

Chemical specificity of heart muscle. B. KISCH (Klin. Woch., 1935, 14, 145—146).—A review. R. N. C.

Specific gravity and water content of the brains of vertebrate animals. I. Birds. L. P. KING and M. C. HSUNG (Bull. Nat. Acad. Peiping, 1935, 6, No. 1, 1—47). CH. ABS. (p)

Embryochemistry of *Hynobius*. M. TAKAMATSU (J. Biochem. Japan, 1935, 22, 203—211).—Data are given for the ash constituents and N distribution of the components of the eggs of *H. nebulosus* incubated for varying periods. The principal enzymes present are esterase, nucleinase, glycogenase, and glycerophosphatase. F. O. H.

Chemistry of blow-fly larvæ. M. TOMITA and T. KUMON (Z. physiol. Chem., 1936, 238, 101—104).—The amounts of various inorg. ions (mostly Na and  $PO_4$ ) and the nature of the proteins and enzymes in the larvæ are recorded. R. S. C.

Distribution of lead in human bones. S. L. TOMPSETT (Biochem. J., 1936, 30, 345—346; cf. A., 1935, 1160).—In bones from persons having had no special exposure to Pb the amounts of Pb per kg. of fresh material were: rib 4.0—17.5, vertebra 3.4—16.5, femur 18.2—108.3, and tibia 15.3—96.5 mg. W. McC.

Organic constituents of bone. T. INOUE (Tohoku J. Exp. Med., 1935, 26, 433—440).—Total C of the substantia compacta of the shaft of the rabbit femur, excluding preformed  $CO_2$ , ranged from 8910.5 to 11596.6 mg. (average 9744.6) and total N from 3119.6 to 3387.8 mg. (average 3269.4) per 100 g. of dry substance. The ratio total C: total N suggests that ossein forms the principal part of the org. ground substance. Residual C was 333.1—568.3 mg. (average 443.2) and the residual N 94.9—171.1 mg. (average 132.1). There was no definite sex difference. Calc. on org. ground substance, bones are richer in residual C and N than is blood. The results indicate that carbohydrates and fats are the most important substances metabolised in bone. NUTR. ABS. (m)

Copper content of some human and animal tissues. P. F. HAHN and E. FAIRMAN (J. Biol. Chem., 1936, 113, 161—165).—In the liver and spleen of dogs suffering from experimental anæmia, Cu tends to rise to high levels as Fe falls towards zero. In man, no marked change in Cu is found in various pathological conditions. Fœtal and infant livers are comparatively rich in Cu, so are the livers of patients with Mediterranean anæmia, although Fe (hæmosiderin) is high. F. A. A.

Phosphorus compounds in the nymph and butterfly of *Deilephilia euphorbiae*. J. HELLER (Compt. rend. Soc. Biol., 1936, 121, 414—416).—Analytical vals. for the butterflies and for the whole nymph and its organs are given. HCl-hydrolysable P (adenosinetriphosphoric acid) is high in the butterflies, especially in the male, but very low in the nymph. Intestinal P in the nymph is entirely inorg.; total P in the adipose tissue is as high as in the hæmolymph, muscles, and intestine. R. N. C.

**Calcium and magnesium content of the flesh of various animals.** M. TAKAMATSU (*Z. physiol. Chem.*, 1936, 238, 99—100).—Ca and Mg were determined in the muscle of 20 animals. Unusually high vals. are: adder, Ca 1.2524, Mg 2.5268; snail, Ca 1.3202, Mg 2.7673; clam, Ca 0.7819; crab, Ca 0.8424% (as oxides) of the dried muscle. R. S. C.

**Sodium content of mammalian muscle.** F. PODOLSKY and G. MALORNY (*Pflüger's Archiv*, 1935, 236, 339—347).—Na of the ash of mammalian muscle is slightly > that of the equiv. Cl, the excess representing Na of the fibres. The excess is of the same order of magnitude as in muscle of cold-blooded animals. Red and white muscles exhibit no important differences in Na content, but in heart-Na is slightly > that in skeletal muscle, particularly in pigs, rabbits, and man. R. N. C.

**am-Glucose in the animal organism.** H. K. BARRENSCHEEN and H. FANTA (*Biochem. Z.*, 1936, 283, 382—389).—When O<sub>2</sub> is bubbled through warm dil. glucose solutions, no oxidation occurs. On adding these solutions to blood, liver, or muscle the filtrates obtained by pptn. with EtOH-COMe<sub>2</sub> and treatment with colloidal Fe(OH)<sub>3</sub> show a decrease in total reducing power of 20—50%, according to the duration of the experiment and the organ used. This decrease is not due to oxidation, but concerns the fermentable portion of the sugar, 60—78% of which is now oxidisable with animal C. This oxidisable portion may be am-glucose. P. W. C.

**Comparative determination of hepatic glycogen by the cupric and iodometric methods.** H. BERRY, B. GOUZON, and C. MAGNAN (*Compt. rend. Soc. Biol.*, 1936, 121, 616—619).—The Cu method gives identical results whether or not the glycogen has previously been pptd. with EtOH; the results are also identical with those by the I method. The Cu-reducing power after Hg deproteinisation is due solely to an aldose. R. N. C.

**Micro-determination of liver-glycogen.** H. BERRY, B. GOUZON, and C. MAGNAN (*Compt. rend. Soc. Biol.*, 1936, 121, 614—616).—The liver is autoclaved with 30% KOH, and again after acidification with HCl. After deproteinising with Hg(NO<sub>3</sub>)<sub>2</sub>, and removing excess of Hg, the liberated glucose is determined by the micro-modification of Bertrand's method. R. N. C.

**Mixed glycerides of salicylic acid, and fatty acids.**—See this vol., 453.

**Fatty acids of phrenosin and kersin.**—See this vol., 454.

**Halibut-liver oils. Vitamin-A content of pilchard oil.**—See B., 1936, 242.

**Polyethenoid acids of the n-octadecane (C<sub>18</sub>) series in aquatic animal oils.**—See B., 1936, 204.

**Lipochromes of the frog (*Rana esculenta*).** L. ZECHMEISTER and P. TUZSON (*Z. physiol. Chem.*, 1936, 238, 197—203; cf. this vol., 97).—The liver contains carotene (I) ( $\alpha$ - and  $\beta$ -) (25% of total pigment), lutein (II), zeaxanthin (III), free and esterified xanthophyll (IV), and small amounts of other lipochromes; the skin and fat glands, chiefly esterified (IV) with

(I), (II), and (III); and the ovaries, (I), (II), and (III). W. McC.

**Colorimetric determination of cholesterol in liver oil.** K. HOTTA and M. KAWAJI (*Nagoya J. Med. Sci.*, 1935, 9, 23—24).—Volatile acids are removed by heating the oil with 0.9% aq. NaCl in a stream of air; after saponification with 25% aq. KOH at 150° for 30 min. cholesterol (0.34—0.54%) is determined by the Embden-Miyamori method.

NUTR. ABS. (m)

**Fate of carotene in the animal organism.** O. BAILLY (*Bull. Acad. méd.*, 1932, 108, 932—935).—The adrenal glands are by far the richest organs of the body in carotene (I), which is localised in the cortex in concns. of the same order as that in carrots. The (I) of bovine adrenals is  $\beta$ -carotene, similar to that found in the ovary. R. N. C.

**Carotenoid pigments in fishes. II. Effects of coloured backgrounds and of ingested carotenoids on the xanthophyll content of *Girella nigricans*.** F. B. SUMNER and D. L. FOX (*J. Exp. Zool.*, 1935, 71, 101—123).

NUTR. ABS. (m)

**Anti-anæmic principle of liver.** J. F. WILKINSON (*Lancet*, 1936, 230, 354—356).—The claim (A., 1935, 885) that Reinecke acid can be used further to purify and increase the potency of the anti-anæmic principle has been confirmed. L. S. T.

**Alleged occurrence of "Krampfstoffe" in acetone extracts of the mammalian brain.** E. HOLMES (*J. Physiol.*, 1935, 85, 400—408).—COMe<sub>2</sub> extracts of the brain contain no substances affecting the central nervous system, but a cardiac depressor.

R. N. C.

**Nitrogenous constituents of the stomach wall of dogs.** K. IKEYAMA (*J. Biochem. Japan*, 1935, 22, 397—407).—Total N and constituent NH<sub>2</sub>-acids (most of which were isolated) were determined in the mucosa and muscle layers of the fundus, cardiac, and pyloric regions. F. O. H.

**Significance of carnitine in muscle.** E. STRACK, P. WÖRDEHOFF, and H. SCHWANEBERG (*Z. physiol. Chem.*, 1936, 238, 183—196).—A simple process for isolating carnitine (I) (1.8% calc. as betaine) from meat extract is described. (I) and acetyl-carnitine (II) have little biological activity, but (I) is accompanied by very small amounts of a substance which persistently adheres to the Au salt of (I) and yields an active Ac derivative. Atropine counteracts the activity of this substance and phytostygmine increases it. (II) yields a sparingly sol. compound with AuCl<sub>3</sub>. W. McC.

**Part played by carnosine in muscles.** E. SAVRON (*Ukrain. Biochem. J.*, 1934, 7, No. 1, 53—61).—The carnosine content of muscle varies in different animals. Vals. for white are > those for red muscle. None occurs in pigeons, rats, guinea-pigs, or dogs. CH. ABS. (p)

**Micro-determination of creatine in muscle.** A. V. PALLADIN (*Ukrain. Biochem. J.*, 1934, 7, No. 1, 163—171).—Muscle is mixed with sand and boiled with aq. NaCl and AcOH. The filtered residue is re-extracted 8—10 times with H<sub>2</sub>O. The combined

extract is boiled with picric acid and the creatinine produced is determined colorimetrically.

CH. ABS. (p)

**Relation between functional requirements, acetylcholine reaction, and glutathione content of bird muscles.** L. CASSEL (Pflüger's Archiv, 1935, 236, 30—35).—The glutathione content of the wing muscles of flying birds is highest in birds that make long flights. Male birds contain > females. Ascorbic acid in the breast muscles is the same in good and bad flyers.

R. N. C.

**Muscle extractives of hibernating giant salamander (*Megalobatrachus japonicus*).** T. IWA-SAKI (J. Biochem. Japan, 1935, 22, 233—242).—From aq. extracts of the muscles were isolated creatine, creatinine, adenine, xanthine, hypoxanthine, histidine, methylguanidine, lysine, choline, and *D*-lactic acid.

F. O. H.

**Acetylcholine and choline in organ extracts.** F. PLATTNER and H. TSUDZIMURA (Pflüger's Archiv, 1935, 236, 175—180).—There is no evidence of a correlation between acetylcholine, choline, and esterase in the organs of the cat. Acetylcholine-like substances are not affected by thyroidectomy or adrenalectomy.

R. N. C.

**Composition of the protamines of sturgeon.** M. A. LISSITZIN and N. S. ALEXANDROVSKAJA (Z. physiol. Chem., 1936, 238, 54—58).—The protamines of the milt of *Acipenser huso*, *guldensstädtii*, and *stellatus* are probably identical, the sulphate being  $C_{35}H_{74}O_7N_{18} \cdot 3H_2SO_4$  (amount of  $H_2SO_4$  varies with method of prep.),  $[\alpha]$  about  $-55^\circ$  in  $H_2O$ , and  $NH_2$ -, arginine-, histidine-, and lysine-N being about 8, 72, 10.5, and 6% of the total N, respectively.

R. S. C.

**Preparation of *b*-thymonucleic acid by nucleogelase.** F. FEULGEN (Z. physiol. Chem., 1936, 238, 105—110).—*b*-Thymonucleic acid (free from *a*-isomeride) is prepared (a) from cell nuclei (e.g., heads of herring sperm) by digestion with slightly alkaline ( $Na_2CO_3$ ) 0.5% pancreatin solution, pptn. from alkaline (NaOH) solution by EtOH, acidification with AcOH, dehydration with EtOH, and desiccation, or (b) from natural organs (e.g., thymus glands) by liquefaction with about 5.5% NaOH (15 min. at  $65^\circ$ ), addition of  $NH_4Cl$ , pptn. with EtOH, and enzymic degradation of the ppt. as in (a) (cf. A., 1914, i, 888).

R. S. C.

**Form of proteins in blood-plasma and bone-marrow in the normal organism.** H. KEILHACK (Arch. exp. Path. Pharm., 1936, 180, 440—457).—Data are given for the contents of the various proteins in rabbit's plasma [7.0% total protein; approx. 0.30% fibrinogen (I)] and bone-marrow [average 3.2% total protein; 1.095% (I)]. The relation between the high (I) content of bone-marrow and the blood constituents is discussed.

F. O. H.

**Chemical constitution of liver-proteins.** F. F. URBAN (Biochem. Z., 1936, 283, 435—453).—The protein of cat's liver washed free from blood is investigated. About half of the protein is extractable by salt solutions, the globulin (I) : albumin (II) ratio in the extract being 7:3. The (II) fraction is P-free. The (I) fraction after repeated pptn. with

$(NH_4)_2SO_4$  contained 0.7% P. After pptn. also with urea, the P content fell to 0.3% and the purine-N to zero. The differences in total N, tyrosine, tryptophan, histidine, phenylalanine, cystine, arginine, lysine, etc. contents of the (I) and (II) fractions are small and considerably < the differences with serum-proteins.

P. W. C.

**Thiol and disulphide groups of proteins. II, III. Reducing groups of proteins.**—See this vol., 352.

**Ultrafiltration of proteins through graded collodion membranes. II. Haemocyanin (*Helix*), edestin, and ovalbumin.** W. J. ELFDON and J. D. FERRY (Biochem. J., 1936, 30, 84—91).—The influence of medium, of  $p_H$ , and of concn. of neutral salts on the filterability of the above proteins is investigated, the best results being obtained in Hartley's broth at  $p_H$  7—8. The filtration end-points for haemocyanin (*Helix*) of 55 m $\mu$  and for edestin of 18 m $\mu$  are established, indicating particle sizes of 18—28 m $\mu$  and 6—9 m $\mu$ , respectively. The results confirm the val. of the factor employed for deducing particle size from porosity of the membrane which just completely retains the disperse phase.

P. W. C.

**Action of radioactive substances on proteins.**—See this vol., 301.

**Electrical orientation of wool cells.**—See this vol., 414.

**Proteins of body-fluids. I. Quantitative and qualitative aspects. II. Application of physical data.** C. ACHARD (Bull. Acad. Méd. Roumanie, 1936, 1, 15—25, 26—30).—I. The nature and content of proteins in body-fluids in health and disease are discussed.

II. The Tyndall effect,  $\sigma$ , adsorption on C, fluorescence, and effect of dilution and flocculation with  $Fe(OH)_3$  of normal and pathological body-fluids are discussed.

F. O. H.

**Influence of high environmental temperature on the secretion and composition of milk.** S. BARTLETT (J. Dairy Res., 1935, 6, 283—288).—High temp. caused a lowering of the % of fat and solids-not-fat in milk. The depression in total yield was small.

A. G. P.

**Factors affecting milk and butter-fat secretion.**

I. Variations in fat weight, fat percentage, and the amount of fat in milk required to make a given weight of butter. II. Colour of the butter-fat. E. O. WHETHAM and J. HAMMOND (J. Dairy Res., 1935, 6, 320—339, 340—352).—I. The size of the fat globule is probably controlled by the rate of formation of fat in the cell and the rate of milk secretion. The influence of age, stage of lactation, and breed are examined. The ratio of the wt. of fat in milk required to make 1 lb. of butter is a measure of variations in the size of the fat globules.

II. Effects of genetic and dietary factors are examined.

A. G. P.

**Daily variations in butter-fat content of milk.** Z. CZUKÁS (Mezőg. kutat., 1935, 8, 270—278).—The daily average butter-fat % of cows' milk varied greatly,

(2.4–5.5). Morning milk contained 40% < evening milk and 30% < noon milk. These differences could not be eliminated by regulating the milking periods. NUTR. ABS. (m)

**Component fatty acids of goat milk fat.** R. W. RIEMENSCHNEIDER and N. R. ELLIS (J. Biol. Chem., 1936, 113, 219–233).—The fat of the milk of goats fed on a regulated diet contained undecolic, pentadecolic, palmitoleic, oleic, hexoic, octoic, decolic, myristic, palmitic, stearic, and arachidonic acid, and a mixture of saturated acids containing tetracosanoic and cerotic acids. H. D.

**Effect of type of feed on the solids-not-fat content of milk.** L. L. ROUX, G. N. MURRAY, and D. J. SCHUTTE (Onderstepoort J. Vet. Sci., 1935, 4, 167–197).—Rations containing identical amounts of protein and total digestible nutrients were fed to 3 groups of cows; group (1) received a high concentrate ration, group (2) high dry roughage, and group (3) high succulent rations. In group (1) solids-not-fat rose normally with advance of lactation, whilst groups (2) and (3) showed a fall. The milk production of group (1) did not decrease as rapidly as that of groups (2) and (3). NUTR. ABS. (m)

**Yield and composition of ewe's milk.** W. GODDEN and C. A. PUDDY (J. Dairy Res., 1935, 6, 307–312).—Analytical data are recorded. No appreciable difference in milk composition resulted from wide variations of Ca in the ration. A. G. P.

**Milk of a typical herd of Shorthorn cows.** III. Nitrogen distribution, chloride, lactose, copper, and iron contents over a period of two years. W. L. DAVIES (J. Dairy Res., 1935, 6, 362–368).—Analyses are recorded and discussed. A. G. P.

**Free lactic acid in fresh milk.** B. GROSS and C. OLIVEIRA (Rev. Quim. Farm., 1935, 1, 117–120).—Fresh milk, or its serum, had  $p_H$  6.65–6.85, whereas the val. calc. on the assumption that its acidity is due to lactic acid is about 2.8. Experiments described indicate that no free lactic acid or lactates are present. L. A. O'N.

**So-called normal lead of human milk.** M. KASAHARA and S. I. NOSU (Jahrb. Kinderheilk., 1935, 145, 78–80).—52 out of 87 samples of milk from women living in an area having a service  $H_2O$  supply contained Pb (trace to 0.18 mg. per litre). Out of 15 samples from women in rural districts only 3 contained Pb (0.04–0.11 mg. per litre). NUTR. ABS. (m)

**Excretion of drugs in milk.** N. T. KWIT and R. A. HATCHER (Amer. J. Dis. Children, 1935, 49, 900–904).—Morphine, codeine, and phenolphthalein are not secreted in human milk. Salicylic acid, I', and Br' appear in milk after administration. CH. ABS. (p)

**Plasma-protein determinations in lactating women.** S. C. PEACOCK and W. F. HINMAN (Amer. J. Physiol., 1935, 113, 235–237).—The excretion of caseinogen in the milk has no recognisable effect on the blood-proteins. R. N. C.

**Crystallisation of [sodium] chloride in presence of cerebrospinal fluid.** P. TOMESCO,

I. COSMULESCO, and F. SERBAN (Bull. Acad. Méd. Roumanie, 1936, 1, 133–140).—NaCl in presence of cerebrospinal fluid crystallises in various abnormal forms dependent on the composition of the fluid; the phenomenon is probably of diagnostic val.

F. O. H.

**Lymph-sugar.** J. W. HEIM, R. S. THOMSON, and F. C. BARTTER (Amer. J. Physiol., 1935, 113, 548–554).—Lymph- and plasma-sugar in the dog are almost identical under certain conditions; the glucose-tolerance curves are similar. Sugar administered *per os* or intravenously enters the lymphatic system readily, and is removed at about the same rate as from blood. R. N. C.

**Salivary secretion.** W. FELDBERG and J. A. GUIMARAIS (J. Physiol., 1935, 85, 15–36). R. N. C.

$p_H$  of normal resting saliva. I. Variations with age and sex. R. E. BRAWLEY (J. Dent. Res., 1935, 15, 55–77).—The average  $p_H$  was 6.75, there being no significant difference between the two sexes. NUTR. ABS. (m)

**Bile pigment metabolism.** I. Breakdown of blood pigments to protoporphyrin by the liver and other organs. Demonstration of a fermenting action. H. T. SCHREUS and C. CARRIÉ (Klin. Woch., 1934, 13, 1670–1673).—The liver is able to form protoporphyrin from hæmoglobin or hæmatin; the process is not associated with life or survival of the cells, but probably with the action of a hæmase. Within certain limits the amounts of fermented substances and of the products of reaction are proportional. Optimum conditions are 37–60° and  $p_H$  3–5; the action of the enzyme is restrained by EtOH, Et<sub>2</sub>O, CHCl<sub>3</sub>, CMe<sub>2</sub>, and glycerol, inhibited by cooling to 0°, and destroyed by boiling. R. N. C.

**Determination of bile salts in human bile.** R. GOIFFON, F. NEPVEUX, and CHALEIL (Compt. rend. Soc. Biol., 1936, 121, 425–427).—Proteins are pptd. from bile with the Folin-Wu reagent, and pigments with FeCl<sub>3</sub> and NH<sub>3</sub>. The bile salts are dissolved in aq. EtOH, evaporated alone and with AcOH, extracted with C<sub>6</sub>H<sub>6</sub> to remove fats, dissolved in 0.1N-NaOH, and pptd. with 0.1N-HCl saturated with (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>, the homogeneous suspension being examined photometrically. R. N. C.

**Determination of free and combined cholesterol in bile.** C. RIEGEL and H. J. ROSE (J. Biol. Chem., 1936, 113, 117–124).—A modification of the Schoenheimer-Sperry (A., 1934, 1240) procedure for the determination of cholesterol in blood is used. F. A. A.

**Rabbits bile.** I.—See this vol., 469.

**Toad bile.** III, IV.—See this vol., 469.

**Bilifuscin.** E. WEINBERGER (Z. physiol. Chem., 1936, 238, 124–128).—Bilifuscin is C<sub>12</sub>H<sub>18</sub>O<sub>3</sub>N. It is isolated impure from human biliary calculi (cf. A., 1901, i, 283). R. S. C.

**Effect of peptones and certain extracts of small intestine on the secretion of succus entericus.** E. S. NASSET and H. B. PIERCE (Amer. J. Physiol., 1935, 113, 568–577).—Witte's peptone contains a secretagogue which stimulates the jejunal glands when

administered *per os* or intravenously. It is extracted, free from depressor, by 70% EtOH, and is thermostable, but destroyed by erepsin or trypsin. It is not present in other peptones. Another secretagogue, which resists the digestive enzymes, but is destroyed by boiling in alkali, is extracted from the small intestines of pigs or dogs by acidified 70% EtOH.

R. N. C.

**Acidity of gastric juice and the diluting secretion of the stomach.** T. ENGSTRÖM (Acta med. scand., 1935, Suppl. 66, 73 pp.).—Gastric secretion in cats following administration of histamine (I) or EtOH is used to study regulation of gastric acidity. Intraglandular regulation by a diluting, HCl-free secretion is of primary importance. True hyperacidity,  $\approx$  about 170 millimol., exists. There was no parallel between blood-(I) and intensity of secretion. With continuous intravenous injection of (I), intensity of secretion increased steadily and appeared to tend towards a max. NUTR. ABS. (m)

**Histamine-like substance in the gastric juice.** C. L. BROWN and R. G. SMITH (Amer. J. Physiol., 1935, 113, 455—463).

R. N. C.

**Some physiological and physical aspects of the surface tension of urine.** P. W. PERRYMAN and C. F. SELOUS (J. Physiol., 1935, 85, 128—144).—A modification of the max. bubble pressure apparatus for determination of  $\sigma$  is described; it can be used to follow changes of  $\sigma$  with temp. and with time up to 2 hr. The  $\sigma$ -time curves for urine are logarithmic, in both normal and pathological urines; the changes are not due to proteins or absorption of CO<sub>2</sub>, but probably to slow adsorption of capillary-active substances. The  $\sigma$ -temp. curve is linear up to 54°, after which the decrease becomes more rapid. Variations of  $\sigma$  are not related to ingestion of food or liquid, but in females  $\sigma$  shows a cyclical variation corresponding with the menstrual cycle.  $\sigma$  is not related to *d*, or the presence of pathological constituents in the urine, and is not correlated with any sp. disease or group of diseases.

R. N. C.

**Chemical basis of the Ehrlich diazo-reaction with urine.** I. P. SACHS. II. P. SACHS and H. KLOSS (Z. klin. Med., 119, 381—402, 551—563; Chem. Zentr., 1935, i, 3019—3020).—I. A cryst. dichloroazobenzene dye, C<sub>31</sub>H<sub>24</sub>O<sub>7</sub>N<sub>6</sub>Cl<sub>4</sub> (Bz<sub>6</sub> and Bz<sub>7</sub> derivatives), is isolated.

II. By-products of high mol. wt. are formed in the reaction, the pathological significance of which is discussed.

H. N. R.

**Detection of histidine in urine as a reaction for pregnancy.** N. C. LOUROS (Klin. Woch., 1934, 13, 1156; Chem. Zentr., 1935, i, 3961).—The Kapeller-Adler reaction (A., 1933, 1094) is unsuitable, both for detecting histidine and as a reaction for pregnancy.

H. N. R.

**Elimination of xylose, creatinine, and urea by the perfused mammalian kidney.** A. HEMINGWAY (J. Physiol., 1935, 84, 458—468).—The average creatinine (I)/xylose (II) and urea/(II) clearance ratios in the isolated perfused kidney are 1.72 and 0.85, respectively, and are within the range of the vals. obtained from normal animals. Plasma concn.

decreases (I) elimination without affecting (II) and urea; (II) elimination  $\propto$  the glomerular filtration rate.

R. N. C.

**Excretion of inulin, creatinine, xylose, and urea in the normal rabbit.** B. I. KAPLAN and H. W. SMITH (Amer. J. Physiol., 1935, 113, 354—360).—Excretion of inulin (I), creatinine (II), xylose (III), and urea increases with urine flow. Simultaneous excretions of (I) and (II) are equal, regardless of urine flow or plasma-(II) level, and are  $>$  those of (III) and urea.

R. N. C.

**Excretion of kynurenic acid by the mammalian organism. Identification of small amounts of kynurenic acid.** W. G. GORDON, R. E. KAUFMAN, and R. W. JACKSON (J. Biol. Chem., 1936, 113, 125—134).—50—100 mg. of kynurenic acid (I) may be identified and determined as the Me ester. The rat, guinea-pig, and Dalmatian dog excrete (I) after administration of tryptophan. The cat does not excrete (I) under these conditions, but ingested (I) is excreted unchanged.

F. A. A.

**Properties of reducing material in certain fractions of normal urines. I. Nature of the free fermentable sugars and the fermentable sugars produced on hydrolysis in fasting urines.** V. J. HARDING, T. F. NICHOLSON, and R. M. ARCHIBALD. II. Effect of diet on hydrolysable sugar in urine. Nature of this sugar. V. J. HARDING, T. F. NICHOLSON, and S. H. JACKSON (Biochem. J., 1936, 30, 326—334, 335—341).—I. Conc. solutions of carbohydrate are obtained from human urine by successive treatment with basic Pb acetate (I), HgSO<sub>4</sub>-BaCO<sub>3</sub>, and CuSO<sub>4</sub>-Ca(OH)<sub>2</sub>. Differential fermentation of the solutions (e.g., with *Saccharomyces Marxianus*) shows the presence, before and after dil. acid hydrolysis, of glucose (II) and galactose (III) and, in some cases, of very small amounts of fructose and mannose. Probably most, if not all, of the fermentable sugar produced on hydrolysis is derived from the non-fermentable reducing fraction, not from a non-reducing precursor. Almost all the sugar of urine is N-free.

II (cf. A., 1931, 1443). Meals consisting chiefly of fat, fruit, and starch, respectively (but not those consisting chiefly of protein), cause increase in the amounts of substances giving rise to fermentable sugar on hydrolysis, excreted in the urine during 4 subsequent hr., the increase being almost entirely due to (II)-producing substances. A small amount of (II)-producing material, pptd. by (I) and HgSO<sub>4</sub>-BaCO<sub>3</sub> but not by Lloyd's reagent, occurs in fasting and non-fasting urines, but not after fat and fruit meals. About 33% of the hydrolysable material has reducing power, the reducing group being in the (II) mol. All (III) produced on hydrolysis exists combined through its reducing group, possibly as lactose.

W. McC.

**Reducing power of urine. II.** H. K. BARRENSCHEEN and H. PRINZ (Biochem. Z., 1936, 284, 99—107; cf. A., 1930, 806).—The reducing material is separated (60%) by adsorption on Al<sub>2</sub>O<sub>3</sub> (optimal at *p*<sub>H</sub> 7.73) and kaolin (optimal at *p*<sub>H</sub> 1.17). The part of the material which loses its reducing power on treatment with CH<sub>2</sub>O is preferentially adsorbed (max.

at  $p_H$  6.24 and 7.73) on kaolin, and is not removed by successive elution with aq.  $NH_3$  and dil.  $AcOH$ , which removes the other part. This part appears to consist of substances related to homogentisic acid.

W. McC.

**Isolation and identification of combined oestriol in human pregnancy urine.** S. L. COHEN and G. F. MARRIAN (Biochem. J., 1936, 30, 57—65).—A method is described for isolation from human pregnancy urine of a  $H_2O$ -sol.,  $Et_2O$ -insol., non-cryst. substance, m.p. 193—197° (decomp.), containing approx. 50 wt.-% of oestriol. The composition and the Ba content of the Ba salt agree with those required for an oestriolglycuronic acid,  $C_{24}H_{32}O_9$ . The substance gives strong naphthoresorcinol and Millon tests, but does not reduce Benedict's solution until after hydrolysis.

P. W. C.

**Excretion of oestrin by the kidneys of the pregnant mare.** S. KOBER (Acta Brev. neerl. Physiol., 1935, 5, 34—35; Chem. Zentr., 1935, ii, 238).—The folliculin content of mare's urine rises suddenly during the 5th and 6th months of pregnancy, and falls again during the last two months.

G. H. F.

**Bence-Jones protein.** H. TSUTSUI (J. Biochem. Japan, 1935, 22, 343—350).—Reactions for urine containing the protein (I) are given. The N distribution of isolated (I)  $\{[\alpha]_D - 95.78^\circ$  (1.305% solution in 0.1N-NaOH), isoelectric point  $p_H$  4.72} is tabulated. (I) is hydrolysed by gastric juice or trypsin. Its pathogenesis is discussed.

F. O. H.

**Colorimetric determination of urinary protein, plasma-protein, urinary and plasma-albumin. Salting out of these proteins.** H. BERGLUND and W. DE M. SCRIVER (Acta med. scand., 1935, 86, 82—87).—Methods with an accuracy of 3—5% are described.  $Na_2SO_4$ , essentially in the concns. used by Howe, is used for fractionation. N is determined by nesslerisation. The acid digestion of protein requires more heat than is required for determination of non-protein-N of blood.

NUTR. ABS. (m)

**Determination of sulphate in urine.**—See this vol., 442.

**Determination in series of the oxalic acid content of urine.** K. KOCH (Biochem. Z., 1936, 283, 422—432).—A method which requires 40 c.c. of urine and determines 0.04—0.1 mg. of  $H_2C_2O_4$  is described. 15—30 double determinations can be carried out per day.

P. W. C.

**Spectrographic determination of phenol added to urine.** G. BARAC (Compt. rend., 1935, 201, 1433).—The urine is treated successively with basic Pb acetate,  $Na_2HPO_4$ , and HCl, extracted with  $Et_2O$ , and the extract is examined (this vol., 126).

F. O. H.

**Determination of *p*-bromophenylmercapturic acid in the urine of the dog.** J. A. STEKOL (J. Biol. Chem., 1936, 113, 279—288).—A gravimetric (using the  $HgCl_2$  complex) and an iodometric titration method are described.

H. G. R.

**Strychnine and barbituric acids.** M. E. KER-GONOV (Bull. Trav. Soc. Pharm. Bordeaux, 1935, 73, 53—61; Chem. Zentr., 1935, i, 3822).—Extraction

methods for the determination of these substances in urine are described.

H. N. R.

**Spectrochemical study of aplysiopurpurin.** M. FONTAINE and A. RAFFY (Compt. rend. Soc. Biol., 1936, 121, 735—736).—Aplysiopurpurin in acid  $Zn(OAc)_2$  solution (cf. A., 1931, 1443) shows absorption bands at 501, 552, and 601  $m\mu$  and fluorescence bands at 518, 568, 617, and 644  $m\mu$ . When obtained in the solid state by pptn. with  $(NH_4)_2SO_4$ , it does not fluoresce; it is therefore related to mesobiliviolin, and is probably a breakdown product of chlorophyll and phycocchromoproteins absorbed by *Aplysia*.

R. N. C.

**Uroporphyrin in acute hæmatoporphyrinuria.** E. MERTENS (Z. physiol. Chem., 1936, 238, I—II).—The urine contained, in addition to a little coproporphyrin, a uroporphyrin (I) [ $Me_8$  ester (II), m.p. 258° (Cu compound, m.p. 304°)]. Decarboxylation of (I) with HCl under pressure gives coproporphyrin III and hence (I) is uroporphyrin III. The mother-liquor from (II) contained a  $MeOH$ -sol. ester, m.p. 240°.

W. McC.

**Urinary porphyrins in disease.** K. DOBRINER (J. Biol. Chem., 1936, 113, 1—10).—A method for separating and identifying porphyrins in urine is described. An increased excretion of coproporphyrin I is characteristic of most diseases, but pigment cirrhosis and liver tumour lead to excretion of coproporphyrin III. In two cases uroporphyrin I was isolated, and an unknown porphyrin ( $Me$  ester, m.p. 222°) was obtained. The formation of these porphyrins is discussed.

J. N. A.

**Acriflavine as a urinary antiseptic.** E. W. ASSINDER (Lancet, 1936, 230, 304—305).—Acriflavine is strongly antiseptic towards the gonococcus.

L. S. T.

**Phosphatase of the plasma and its variations in disease.** C. JIMÉNEZ DÍAZ, E. BASSADONE, and S. CLARIANA (Rev. españ. Enferm. Aparat. digest. Nutric., 1935, 1, 5—20).—Average vals. found were 0.142 Kay unit in adults and 0.26 in children. Increases in rickets, osteomalacia, bone diseases, degenerative rheumatism, and liver disease are noted.

NUTR. ABS. (m)

**Scurvy in Addison's disease and the value of the catalase index in adrenal insufficiency.** L. NORRHO (Deut. Arch. klin. Med., 1935, 177, 499—508; Chem. Zentr., 1935, ii, 245).—The blood-catalase index has no diagnostic significance in Addison's disease.

G. H. F.

**Adrenal disease in relation to hypoglycæmia and death.** J. C. NORRIS (Amer. J. Clin. Path., 1935, 5, 120—130).—Hypoglycæmia under these conditions indicates a relationship between liver and adrenals in glucose metabolism.

CH. ABS. (p)

**Correlation of hypertrophy of the adrenal cortex with bodily work and the vitamin-B content of the diet.** A. VON BEZNÁK and J. PERJÉS (Pflüger's Archiv, 1935, 236, 181—189).

R. N. C.

**Amidopyrine and granulopænia.** Reappearance of granulocytosis in a case of recurring agranulocytosis after large doses of amido-

pyrine. L. R. LIMARZI and I. G. MURPHY (J. Lab. Clin. Med., 1935, 20, 616—622). CH. ABS. (p)

Goat's milk anæmia. G. O. KOHLER, C. A. ELVEHJEM, and E. B. HART (Amer. J. Physiol., 1935, 113, 279—284). R. N. C.

Comparison of the anæmia produced by feeding young rats on human, cow's, and goat's milk. H. H. BEARD and T. S. BOGGESS (Amer. J. Physiol., 1935, 113, 642—646). R. N. C.

Blood regeneration in severe anæmia: fractions of kidney, spleen, and heart compared with standard fractions. F. S. ROBSCHT-ROBBINS, G. B. WALDEN, and G. H. WHIPPLE (Amer. J. Physiol., 1935, 113, 467—475). R. N. C.

Chlorophyll and regeneration of blood. Administration of chlorophyll derivatives in chronic hypochromic anæmia. A. J. PATEK, jun. (Arch. Int. Med., 1936, 57, 73—84).—Chlorophyll products when administered either parenterally or orally with comparable amounts of Fe produce blood regeneration. H. G. R.

Liver principle active in pernicious anæmia. C. C. UNGLEY (Nature, 1936, 137, 210—213).—A review. L. S. T.

Treatment of pernicious anæmia with Dakin and West's liver fraction (anahæmin). C. C. UNGLEY, L. S. P. DAVIDSON, and E. J. WAYNE (Lancet, 1936, 230, 349—354).—The prep. is highly active for blood regeneration in pernicious anæmia. L. S. T.

Pathological calcium deposits. D. R. MEEKER and H. D. KESTEN (J. Biol. Chem., 1936, 113, 289—296).—The average composition of calcified deposits in arterial sclerosis is: CaO 49.5, P<sub>2</sub>O<sub>5</sub> 36.1, MgO 0.90%. Calcification of implanted colloid material is increased by toxic doses of vitamin-D preps. and the deposit has the average composition: CaO 46.8, P<sub>2</sub>O<sub>5</sub> 32.7%. H. G. R.

Urinary sulphur in non-specific arthritis. B. D. SENTURIA (J. Lab. Clin. Med., 1935, 20, 855—861).—The total S excreted and the S partition in urine of affected patients are approx. normal. The N/S ratio is lowered in only a few cases. CH. ABS. (p)

Blood-urea in botulism of cattle. P. ROSSI (Compt. rend. Soc. Biol., 1936, 121, 526—527).—Botulism is accompanied by a rise of blood-urea and a fall in renal excretion of urea, both returning to normal on recovery. R. N. C.

Blood-urea and *Brucella* infection in horses. P. ROSSI (Compt. rend. Soc. Biol., 1936, 121, 611—612).—Blood-urea is not appreciably affected. R. N. C.

Carcinogenic chemical compounds. H. A. WEIDLICH (Chem.-Ztg., 1936, 60, 185—187).—A review.

Carcinogenic action of thorium dioxide in the white rat. G. ROUSSY, C. OBERLING, and M. GUÉRIN (Bull. Acad. méd., 1934, 112, 809—816). R. N. C.

Experimental production by œstrin of pituitary tumours with hypopituitarism and of mammary

cancer. W. CRAMER and E. S. HORNING (Lancet, 1936, 230, 247—249). L. S. T.

Cholesterol as a constituent of malignant cells. I. A. BRONSTEIN and D. V. WOLKENSOHN (Acta Cancerologica, 1935, 1, 205—214).—The cholesterol (I) content of the necrotic centre of the Jensen rat sarcoma is 2—2.5 times that of the developing periphery. X-Irradiation *in vivo* does not alter the (I) of the periphery. The (I) of culture media is not changed by growth of sarcoma cells. CH. ABS. (p)

Action of pituitary secretion on tumours. H. DRUCKREY (Arch. exp. Path. Pharm., 1936, 180, 367—380).—Following castration in female rats, the gonadotropic hormone (I) content of the pituitary increases 15—20-fold and, after approx. 7 months, decreases; the thyrotropic hormone content is unchanged. During the period of increased level of (I), development and growth of tumour implants are inhibited, the initially increased respiration decreasing to zero vals.; such non-respiring tumours are not re-implantable. Relations between hormonal influence and tumour growth are discussed. F. O. H.

Effect of cystine disulphoxide on spontaneous tumours of the mouse. F.S.H. FOR THE STAFF OF THE RESEARCH INSTITUTE OF THE LANKENAU HOSPITAL, PHILADELPHIA (Science, 1936, 83, 108—109).—Tumour growth and cell proliferation are retarded. L. S. T.

Variations of polypeptidæmia in cancerous patients treated by intravenous injections of complex salts derived from vitamin-C (ferri-scorbones). F. ARLOING, A. MOREL, A. JOSSERAND, M. CHAMBON, and S. CELLIÈRE (Compt. rend. Soc. Biol., 1936, 121, 683—685).—Polypeptides are increased. R. N. C.

Effect of hæmatoxylin on respiration and glycolysis of cancerous tissue and spleen of cancerous rats. R. IWATSURU and M. KAWAGUCHI (Biochem. Z., 1936, 284, 163—168).—The R.Q. is increased, in presence or absence of glucose, by addition of hæmatoxylin whereas that of spleen and liver of healthy rats is unchanged or slightly diminished; glycolysis in the diseased tissue and spleen is practically unchanged. W. McC.

Genetics, thiol, and cancer. F. S. HAMMETT (Science, 1936, 83, 57).—A discussion. L. S. T.

Cerebroside-containing cerebral cyst. C. TROPP and B. ECKARDT (Z. physiol. Chem., 1936, 238, 31—34).—The liquid from a cerebral cyst contained no inorg. Fe, cholesterol, or P, very little fat and hæmoglobin products, but mainly cerebrin and kerasin and some albumin. A small amount of solid deposit contained Fe and fat. R. S. C.

Gastric secretion in cœliac disease. J. W. OGILVIE (Arch. Dis. Childhood, 1935, 10, 93—98).—The disease is accompanied by lowered [HCl] in gastric juice without true achlorhydria. The increase in total Cl<sup>-</sup> probably results from the higher [Cl<sup>-</sup>] in blood. CH. ABS. (p)

Sulphur metabolism in cystinuria. J. C. ANDREWS and A. RANDALL (Amer. J. Med. Sci., 1935, 189, 301—302).—In a case described, the out-

put of cystine (I) was unaffected by doses of  $\text{NaHCO}_3$  and Na citrate sufficient to maintain urinary  $p_H$  at 7.0–7.5 and to keep (I) in solution, by equimol. proportions of glycine and glutamic acid, or by a high-egg diet. Orally administered (I) is completely oxidised to  $\text{SO}_4^{--}$ . 60–80% of *dl*-methionine is oxidised to  $\text{SO}_4^{--}$ , the remainder being excreted as unoxidised S without change in urinary (I). Cysteine (II) is excreted unoxidised. The (II) content of cystinuric urine increases 25–50% on keeping 24 hr.

CH. ABS. (p)

Sugar and glutathione contents of blood and skin in dermatitis produced by croton oil and by sunburn. C. MONCORPS, R. M. BOHNSTEDT, and R. SCHMID (Arch. Dermatol. Syphilis, 1933, 169, 67–75).—The changes are functions of the intensity of skin inflammation and time.

CH. ABS. (p)

"Soya water-bread" and the use of soya meal in the treatment of diabetes and corpulence. F. SCHELONG (Klin. Woch., 1935, 14, 487–490).—The composition of a comparatively carbohydrate-free "water-bread" prep. from oil-free soya-meal is given, and its therapeutic use is indicated. R. N. C.

Neuropathy in diabetes. Lipin constituents of the nerves correlated with the clinical data. W. R. JORDAN and L. O. RANDALL (Arch. Int. Med., 1936, 57, 414–421).—The phospholipins, cholesterol, and cerebroside of the nerves are reduced in diabetes, the greatest effect occurring in those from the lower part of the leg.

H. G. R.

Inorganic phosphorus in diphtheria. I. NATIN and C. DA RIN (Semana méd., 1935, I, 1148–1149).—Blood-inorg. P is not appreciably abnormal.

CH. ABS. (p)

Hyperglycæmia in diphtheria, carbohydrate metabolism, and treatment with glucose and insulin. I. NATIN and C. DA RIN (Semana méd., 1935, I, 1055–1058).—In diphtheria, deviation of glycæmia is small, but glucose tolerance is frequently disturbed by factors of hepatic origin.

CH. ABS. (p)

Experimental epilepsy. III. Alteration in the protective quality of serum in epileptiform convulsions produced by camphor. V. NEKLUDOV (Kolloid-Z., 1936, 74, 218–221).—During and between the convulsions produced in cats and dogs by injection of camphorated oil, the quantity of blood-serum needed to stabilise a sol of Congo-rubin is increased in severe attacks which end fatally, but is diminished in less severe, non-fatal attacks.

F. L. U.

Lipin diseases. IV. Lipin content of tissues in status epilepticus, toxic encephalopathy, and chronic leptomeningitis. D. M. COWIE and M. C. MAGEE (Amer. J. Dis. Children, 1935, 49, 884–893).—The ratio of phospholipins to cholesterol in liver, spleen, and skeletal muscle in status epilepticus is > in other diseases examined (cf. A., 1934, 550).

CH. ABS. (p)

Rôle of uric acid in gout. H. LUCKE (Deut. med. Woch., 1934, 60, 1783–1786).

R. N. C.

Serum-calcium, -inorganic phosphorus, and -phosphatase activity in hyperparathyroidism,

Paget's disease, multiple myeloma, and neoplastic disease of the bones. A. B. GUTMAN, T. L. TYSON, and E. B. GUTMAN (Arch. Int. Med., 1936, 57, 379–413).—Serum-phosphatase is augmented in the diseases studied. In hyperparathyroidism, multiple myeloma, and neoplastic disease of the bones hypercalcaemia is observed, inorg. P being low in hyperparathyroidism, but normal in other cases. In Paget's disease both serum-Ca and -inorg. P are normal.

H. G. R.

Blood-cholesterol in hypothyroidism. LESNÉ, BRISKAS, and LARDÉ (Bull. Soc. Pédiat. Paris, 1935, 33, 60–62).—The finding of high blood-cholesterol in hypothyroidism is confirmed. In infants, the val. is 2–4 and in children above 15 years 1.3–1.6 g. per litre.

NUTR. ABS. (m)

Blood-cholesterol in arterial hypertension. A. H. ELLIOT and F. R. NUZUM (Arch. Int. Med., 1936, 57, 63–72).—Hypercholesterolaemia was not observed in uncomplicated hypertension or in hypertension associated with vascular degeneration or renal impairment or a low metabolic rate unaccompanied by hypothyroidism. High vals. were generally associated with subnormal body-wt.

H. G. R.

Treatment of hyperinsulinism with insulin. H. J. JOHN (Endocrinol., 1935, 19, 689–694).

R. N. C.

Hypoglycæmic headache. P. A. GRAY and H. I. BURTNESS (Endocrinol., 1935, 19, 549–560).—Migraine and other headache conditions are often associated with low blood-sugar (I). The glucose tolerance curve is of the flat type. Reactivity to insulin (II) is measured by the (II) tolerance test; the fall of (I) below fasting level  $\propto$  the height above the fasting level before injection of (II).

R. N. C.

Van der Bergh reaction (ring test technique) and hæmoglobin-bilirubin interrelation in icterus neonatorum. N. W. ELTON (J. Lab. Clin. Med., 1935, 20, 817–826).—No relationship was apparent between the bilirubin content and changes in hæmoglobin content and no. of erythrocytes.

CH. ABS. (p)

Variations of oxalæmia in liver diseases. A. RODRIGUEZ-OLLEROS (Rev. españ. Enferm. Aparat. digest. Nutric., 1935, 1, 323–332).—Blood- $\text{H}_2\text{C}_2\text{O}_4$  in hepatic disease is > normal. No correlation was found between extent of bilirubinæmia and oxalæmia. Ingestion of 1 g. of  $\text{H}_2\text{C}_2\text{O}_4$  produces in liver patients in 2 hr. a 10–30% increase in oxalæmia, whereas there is no increase in non-hepatic patients. Diets poor or rich in  $\text{H}_2\text{C}_2\text{O}_4$  produce no const. variation in oxalæmia on the day following the diet.

NUTR. ABS. (m)

Carbohydrate exchange after carbohydrate charging and its disturbance in liver diseases. I. Insulin-glucose-water charging. R. MEIER and E. SCHMIEDT (Z. ges. exp. Med., 1935, 95, 277–287; Chem. Zentr., 1935, i, 3950–3951).—Injection of excess of insulin followed by ingestion of excess of glucose and  $\text{H}_2\text{O}$  by healthy man does not generally result in increased carbohydrate combustion, the R.Q. and  $\text{O}_2$  consumption showing little change. In cirrhosis of the liver, combustion is retarded and

continues longer than normally. Lactic acid formation is increased in jaundice. In normal rabbits glycogen is first synthesised, but is later oxidised; it disappears from the liver 3 hr. after ingestion, and is not deposited in the muscles. R. N. C.

**Glucose exchange in liver diseases. II.** E. SCHMIEDT (Z. ges. exp. Med., 1935, 95, 288—294; Chem. Zentr., 1935, i, 3951).—Charging with glucose is not suitable for the diagnosis of liver functional disturbance in man.  $O_2$  consumption shows no characteristic change, but R.Q. exhibits a late rise in cirrhotics. R. N. C.

**Biochemistry of blood of normal and malaria-infected monkeys.** R. C. WATS and B. M. DAS GUPTA (Indian J. Med. Res., 1934, 21, 475—481).—Blood-sugar, -non-protein-N, and -Ca were unchanged by infection, whilst the plasma-cholesterol decreased. Treatment with atebirin, quinine, etc. caused an unexplained increase in inorg.  $PO_4'''$ . CH. ABS. (p)

**Bromide content of blood determined by the method of Leipert and Watzlawek, in mental disease.** M. NAGY and J. STRAUB (Orvosi Hetilap., 1935, 79, 895—897).—In 70% of cases of recurrent psychosis blood-Br' was subnormal (normal 0.9—1.4 mg. per 100 ml.). In the remaining cases and in other mental diseases it was normal or high. NUTR. ABS. (m)

**Mineral metabolism in osteogenesis imperfecta.** W. W. SWANSON and L. V. IOB (Amer. J. Dis. Children, 1935, 49, 958—963).—In affected cases, retention of Na differs more from normal than that of other minerals. Vals. for Ca and P are < normal, and those for S, K, Cl, and N are in the normal range. The Ca and P of bones increase. Viosterol improves retention of Ca and P without affecting that of other minerals. CH. ABS. (p)

**Diagnostic value of pigmentation in paludism. Concentration [of pigment] in blood and urine.** M. CANCIULESCO and R. HIRSCH (Bull. Acad. Méd. Roumanie, 1936, 1, 31—34). F. O. H.

**Poikiloderma atrophicans vasculare (Jacobi).** A. MARCHIONINI and F. BÖHNING (Arch. Dermatol. Syphilis, 1934, 170, 112—122).—Changes in blood-sugar, serum-protein, -alkali reserve, -lactic acid, -cholesterol, -K, and -Ca during a sweat bath with a normal patient and with one almost devoid of sweat glands are examined. CH. ABS. (p)

**Rapid flocculation method for diagnosis of syphilis.** P. RYTZ (Amer. J. Clin. Path., 1935, 5, 159—161).—The reaction is made more rapid by coagulation of blood by heating for 2—3 min. at  $60^\circ$ , sensitisation of serum by  $(NH_4)_2SO_4$ , and use of a stable stock antigen. CH. ABS. (p)

**Calcium therapy in "staggers" in the bullock.** (A) J. R. SHEEHY. (B) J. R. GREIG (Vet. Rec., 1936, 16, 147—148; 202). R. N. C.

**Fistulous withers and poll-evil: calcium therapy.** W. W. LANG (Vet. Rec., 1936, 16, 238). R. N. C.

**Tetany in calves.** B. SJOLLEMA (Vet. J., 1935, 91, 133—137).—In tetany the mineral and, probably, the carbohydrate metabolism are disturbed. Blood-

Ca and -Mg vary irregularly. Tetany is not due to Mg deficiency but probably results from overfeeding with protein. CH. ABS. (p)

**Concentrated diet in childhood tuberculosis and malnutrition.** G. E. PRATT (Arch. Pediatr., 1934, 51, 529—533).—Supplementary milk feeding to increase the calorific val. of the diet and the intake of fat, protein, carbohydrate, Ca, P, vitamin-A and -B<sub>2</sub> increased the gain in wt. and general condition of tuberculous children. CH. ABS. (p)

**Effect of irradiated ergosterol on the phospholipins of the blood in pulmonary tuberculosis.** J. H. REICHART (Diss., Amsterdam, 1935, 64 pp.).—A photo-electric method of determining lipid P was found most accurate. The lipid P content of the blood in 34 normal subjects varied as much as 12% in 6—7 days. The vals. in tuberculous patients, treated with irradiated ergosterol or untreated, were not significantly different from one another or from normal vals. NUTR. ABS. (m)

**Blood-calcium in tuberculosis.** F. MEERSSE-MANN and H. SÉGUIN (Rev. Tuberc. Paris, 1935, [v], 1, 514—528).—Blood-C tends to be low. NUTR. ABS. (m)

**Variations in living matter controlled by chemical laws.** O. RAHN (Biochem. Z., 1936, 284, 40—62).—Vital processes (e.g., heat-inactivation of enzymes, fission processes in the cell, velocity of cell division, biological variation, death of cells) are considered from certain mathematical aspects. F. O. H.

**Basal heat production of the rhesus monkey (*Macaca mulatta*).** N. RAKIETEN (J. Nutrition, 1935, 10, 357—362).—The average basal heat production, 608 kg.-cal. per sq. m. per 24 hr., is the same for both sexes and is not affected by administration of Na amytal. A. G. P.

**Basal metabolism and iodine excretion during pregnancy.** L. ENRIGHT, V. V. COLE, and F. A. HITCHCOCK (Amer. J. Physiol., 1935, 113, 221—228).—Growth of the foetus and supplementary tissues is largely responsible for the increased metabolism accompanying pregnancy, but in adolescent girls there is another stimulatory factor absent in mature women. The increase is smaller if iodised salt is used during pregnancy. I excretion increases 3 weeks before birth, suggesting a possible change in thyroid function. R. N. C.

**Basal metabolism and urinary nitrogen excretion of Oriental women.** A. H. TURNER and F. G. BENEDICT (Amer. J. Physiol., 1935, 113, 291—295).—Basal metabolism is < the prediction standard and that of American women in the same environment. The urinary N excretion shows that proteins in the diet are not abnormally low, and that the fall of basal metabolism is not due to decreased protein metabolism. R. N. C.

**Interpretation of lowered basal metabolic level.** D. L. SEXTON (Endocrinol., 1935, 19, 579—586). R. N. C.

**Heat production in man. II. Output of carbon dioxide as a measure of heat production in basal metabolism.** T. W. ADAMS and E. P.

POULTON (Guy's Hosp. Rep., 1935, 85, 56—75).—Calculations and deductions support the view that, under basal conditions, carbohydrate and fat are burnt in a fixed ratio.  $\text{CO}_2$  production is a direct measure of the amount of combustion.

#### NUTR. ABS. (m)

Increase of the contents of reducing substances (glutathione and ascorbic acid) in the organs in training. K. WACHHOLDER and K. UHLENBROCK (Pflüger's Archiv, 1935, 236, 20—29).—I-reducing substances (I) are increased in the skeletal, heart, and stomach muscles, liver, lungs, and brain of the dog and the rabbit by regulated exercise, the increases being due to glutathione in the first instance, but in many cases to ascorbic acid as well. (I) are decreased in many organs in over-exerted rabbits. In a well-trained dog (I) are decreased in the thyroid and adrenals.

R. N. C.

Effect of muscular exercise on biological processes. E. TAKEDA (Japan. J. Exp. Med., 1935, 13, 471—509, 511—520, 521—527, 529—534, 535—541).—The following changes were observed in dogs as the result of work for 1 hr. on the treadmill: increases in no. of leucocytes and lymphocytes, blood-fat, and residual N, decreases in blood-sugar, no. of erythrocytes, haemoglobin content of the blood,  $\text{CO}_2$ -combining capacity of the plasma, and total urinary N. In dogs fed from infancy on meat diets all these changes were > in dogs fed on vegetable diets.

#### NUTR. ABS. (m)

Changes of volume of muscle as an expression of chemical processes. O. MEYERHOF and W. MOHLE (Biochem. Z., 1936, 284, 1—11).—The changes in vol. which occur in normal and poisoned [with  $\text{CH}_3\text{I}\cdot\text{CO}_2\text{H}$  (I)] muscle on stimulation and in muscle with heat- or (I)-rigor are accompanied by an unexplained contraction, in Ringer's solution somewhat > that in paraffin oil, and especially pronounced during production of lactic acid (II). The dilations are only 40% (Ringer) and 50% (paraffin) of those observed during enzymic (II) production, and the contraction of muscle poisoned with (I) is > the expected val. When valeric acid penetrates muscle, slight contraction occurs.

W. McC.

Is the work of the kidney (due to excretion of urea) a factor in specific dynamic action? A. G. EATON, S. C. CORDILL, and J. L. GOUAUX [with V. CLAY] (J. Nutrition, 1935, 10, 429—436).—The work done by kidneys in the concn. of urine during rapid excretion of urea is not a material factor in the sp. dynamic action of proteins.

A. G. P.

Coefficient *K* of Nicloux in the gudgeon (A) living 24 hours in glucose solutions of increasing concentrations, (B) living in glucose solutions as a function of time. G. FONTÈS, J. BRUNER, and A. LINDENBERG (Compt. rend. Soc. Biol., 1936, 121, 452—455, 456—458).—(A) *K* diminishes as the concn. of glucose increases, the curve being linear. *K* becomes zero when the osmotic pressure becomes double the isotonic val.

(B) *K* shows little variation in a 1.25% solution of glucose, and becomes normal in 5 days. It falls rapidly in 5% solution, rises in 3 days, and then falls again.

R. N. C.

Behaviour of heavy water towards light water in the organism. F. BREUSCH and E. HOFER (Klin. Woch., 1934, 13, 1815—1816; Chem. Zentr., 1935, i, 3882—3883).—From determinations of *d* to  $\pm 5 \times 10^{-7}$  for  $\text{H}_2\text{O}$  mechanically and chemically held in various organs, no fractionation of  $\text{H}_2\text{O}$  and  $\text{D}_2\text{O}$  in the organism could be detected in normal cases, in sarcoma of the lung, in cirrhosis of the liver, or in blood from tuberculous or cancerous cases.

J. S. A.

Effect of ingestion of saline waters on the  $p_{\text{H}}$  of the intestinal tract, the nitrogen balance, and the coefficient of digestibility. V. G. HELLER, J. R. OWEN, and L. PORTWOOD (J. Nutrition, 1935, 10, 645—651).—Assimilation and digestibility of foods, if affected at all, are improved by dissolved salts provided serious disturbance of growth or reproduction does not occur. The  $p_{\text{H}}$  of the intestinal tract is not appreciably altered, but that of the stomach is somewhat affected.

A. G. P.

Respective variations of weight, water, and the constituents of the dry weight in the gudgeon as functions of the external glucose concentration. G. FONTÈS, J. BRUNER, and A. LINDENBERG (Compt. rend. Soc. Biol., 1936, 121, 459—462).— $\text{H}_2\text{O}$  and " $\text{H}_2\text{O}$  impermeable to EtOH" decrease, and non-protein substances increase, as the glucose (I) concn. increases. The dry wt. decreases, the curve being linear. In a 1.25% (I) solution conditions tend to return to normal after 5 days.

R. N. C.

Immediate effects of reduced cooling powers on the water balance and related effects in the human subject. D. H. K. LEE and A. G. MULDER (J. Physiol., 1935, 84, 410—432).

R. N. C.

Permeability and ion concentration in muscle excitation. V. S. ILJIN (Pflüger's Archiv, 1935, 236, 148).—A reply to Ernst and Fricker (cf. A., 1935, 239).

R. N. C.

Absorption of water from common salt and sugar solutions. E. J. McDOUGALL and F. VERZAR (Pflüger's Archiv, 1935, 236, 321—338).— $\text{H}_2\text{O}$  and hypotonic NaCl solutions are rapidly absorbed in the rat and cat; isotonic NaCl is absorbed well in the rat, but in the cat an increase in vol. of the solution sometimes occurs, as in the case of isotonic xylose (I) solutions in both species. The increase in vol. is not accompanied by a change of osmotic pressure, so that blood-crystalloids (II) diffuse into the intestine. Glucose (III) is absorbed from isotonic solution by the rat intestine after 15 min.; the absorption depends on the amount of (II) diffusing in, and is generally so intensive that the solution becomes hypotonic and  $\text{H}_2\text{O}$  is absorbed. Absorption is slower in the cat, no  $\text{H}_2\text{O}$  being resorbed from 5.4% (III). If (III) absorption in the rat is depressed by  $\text{CH}_3\text{I}\cdot\text{CO}_2\text{H}$ ,  $\text{H}_2\text{O}$  behaves as in the case of (I), and the solution becomes hypertonic through diffusion of (II) into the intestine. Increase of the hydrostatic pressure of the small intestine causes an increase in rate of absorption of isotonic NaCl  $\propto$  the increase in pressure.

R. N. C.

Relative significance of electrolyte concentration and tissue reaction in water meta-

**bolism.** H. A. DAVIS and L. R. DRAGSTEDT (Amer. J. Physiol., 1935, 113, 193—199).—Dogs dehydrated by simple H<sub>2</sub>O deprivation retain 0.9% NaCl and 5% glucose better than do normal dogs. Animals with gastric fistulae and consequent alkalosis retain H<sub>2</sub>O slightly better than those with pancreatic fistulae; the latter are extensively depleted of base, chiefly Na, through loss of pancreatic juice, but still cannot retain NaCl. R. N. C.

**Changes in the laid egg.** P. ULRIK and D. DAVIDSEN (Proc. 5th World's Poultry Congr. Rome, 1933, 2, 462—474).—The  $p_H$  of the egg increases from 8.2 when new laid to 9.2 after 12 hr., and to 9.8 in 9 days. Subsequent changes are insignificant. Titration with CH<sub>2</sub>O serves as an approx. index of egg age. CH. ABS. (p)

**Relation between metabolic processes and the ventricular electrogram.** A. S. DALE (J. Physiol., 1935, 84, 433—453). R. N. C.

**Mechanism of intracellular respiration.** D. KEILIN (Bull. Soc. Chim. biol., 1936, 18, 96—130).—A lecture.

**Accuracy of the Barcroft differential manometer in respiration studies.** A. S. CORBET and W. R. WOOLDRIDGE (Biochem. J., 1936, 30, 132—140).—The standard error in the determination of O<sub>2</sub> by the Barcroft technique depends on the duration and replication of the experiments. A statistical method for determining the significance of the difference between means is recommended. H. D.

**Effect of viosterol on oxygen consumption of frog's muscle.** S. GELFAN (Amer. J. Physiol., 1935, 113, 464—466).—O<sub>2</sub> consumption in isolated frog muscle is increased by daily injections of viosterol. R. N. C.

**Effect of thyroxine on tissue oxidation.** G. N. MARKOFF (Beitr. path. Anat., 1935, 94, 377—388; Chem. Zentr., 1935, i, 3561).—Thyroxine (I) augments tissue oxidation in the liver of the rat, but not in the spleen or brain. The increase does not occur until the regular effects of (I) are established. The increase in O<sub>2</sub> consumption in the liver is noticeable 3 days after the last injection of (I), whilst the increase of cellular oxidases is evident immediately after the last injection. R. N. C.

**Effect of liver feeding in relation to oxygen want.** H. B. PARRY (J. Physiol., 1935, 84, 454—457).—Exposure of rabbits to low O<sub>2</sub> tensions does not cause formation in the liver of any factor hæmopoietic to rats. R. N. C.

**Choline and liver respiration.** O. A. TROWELL (J. Physiol., 1935, 85, 356—374).—Choline (I) in concns. > 0.12% increases O<sub>2</sub> consumption by rat's liver- or kidney-tissue, decreases that of cardiac muscle and spleen, and does not affect that of brain. Added fatty acid or glucose does not affect the action of (I). Washed liver-pulp oxidises (I) with uptake of 1 atom of O per mol. (I) does not affect O<sub>2</sub> consumption by aq. liver extract, but in concns. > 0.01% it inhibits CH<sub>3</sub>Ac-CO<sub>2</sub>H production to a degree  $\propto$  the concn., inhibition being complete at 1%; fatty acid increases the inhibition. The effect of (I) on O<sub>2</sub> consumption by liver-tissue is probably the algebraic

sum of (I) oxidation by the liver and inhibition of normal fat oxidation; the increase in O<sub>2</sub> consumption due to the first process is > the decrease due to the second, at all (I) concns. R. N. C.

**Embryochemistry of amphibia. VIII. Oxidative processes in giant salamander's eggs.** F. YAMASAKI. IX. Urea and uric acid in incubated eggs of giant salamander. M. TAKAMATSU and T. KAMACHI (J. Biochem. Japan, 1935, 22, 181—184, 185—187).—VIII. Development of the eggs produces an increase in -SH and in indophenol-oxidase.

IX. The incubated eggs contain 0.0030—0.0047% of urea, but only traces of uric acid. F. O. H.

**Effect of frequency of contraction of the isolated mammalian heart on the consumption of oxygen.** A. E. COHN and J. M. STEELE (Amer. J. Physiol., 1935, 113, 654—658). R. N. C.

**Influence of muscular work on oxidative processes in the animal organism.** L. PAL-LADINA (Ukrain. Biochem. J., 1934, 7, No. 1, 23—30).—The oxidation of PhOH, injected into rabbits, diminishes after muscular work. CH. ABS. (p)

**Comparison of the rates of metabolic activity in the solitary and migratory phases of *Locusta migratoria*.** C. G. BUTLER and J. M. INNES (Proc. Roy. Soc., 1936, B, 119, 296—304).—*L. migratoria* may, according to the conditions, assume either a migratory or a solitary phase. The rate of O<sub>2</sub> uptake per unit area of body surface is higher for locusts in the migratory phase, in all instars after the first. The rate is higher for males than for females in all instars and both phases. The rate diminishes from the first to the third instars, and increases again from the fourth instar to the adult stage. F. A. A.

**Mechanical activity of gut muscle under anaërobic conditions.** B. N. PRASAD (J. Physiol., 1935, 85, 249—266).—The mechanical activity of gut muscle is arrested by asphyxia through exhaustion of its labile carbohydrates. Max. activity is maintained when both glucose and O<sub>2</sub> are supplied to the muscle. CH<sub>2</sub>I-CO<sub>2</sub>H limits considerably the anaërobic activity of the muscle, suggesting a low phosphagen content. R. N. C.

**Relation of rate of growth to diet. III. Comparison of stock rations.** L. B. MENDEL and R. B. HUBBELL [with F. FRANCIS] (J. Nutrition, 1935, 10, 557—563). A. G. P.

**Effect of cereal diets on the composition of body-fat of rats.** H. S. OLCOTT, W. E. ANDERSON, and L. B. MENDEL (J. Nutrition, 1935, 10, 517—523).—The I val. of the body-fat varied with the cereal food given. A. G. P.

**Alimentary value of (A) old, (B) new, maize.** G. NICHITA, N. TUSCHAK, and G. IFTIMESCO (Compt. rend. Soc. Biol., 1936, 121, 563—566, 567—570). R. N. C.

**Effect of differently de-fatted soya-bean meals on the blood picture of domestic animals.** I. ENVER (Diss., Tierärztl. Hochsch., Berlin, 1933; Bied. Zentr., 1935, 6, A, 1).—Effects of extraction with C<sub>2</sub>HCl<sub>3</sub> and with CCl<sub>4</sub> are compared by means

of rabbits and guinea-pigs. The blood picture is not appreciably altered by the use of these solvents.

A. G. P.

Are potato- and maize-starch nutritionally equivalent? F. FISCHLER (Münch. med. Woch., 1935, 82, 57—58; Chem. Zentr., 1935, ii, 243).—Equivalence is established.

G. H. F.

Comparative rachitogenic property of oats and maize. L. L. LACHAT and L. S. PALMER (J. Nutrition, 1935, 10, 565—577).—HCl extracts of oats when purified and freed from excess of NaCl showed rachitogenic properties when fed to rats receiving a mildly rachitogenic diet. With a severely rachitogenic diet the extracts produced no additional effect. Rolled oats and yellow maize are rachitogenic to rats and especially to chickens.

A. G. P.

Influence of diet on the glucose tolerance of the dog. E. M. GREISHEIMER and F. W. HOFFBAUER (J. Nutrition, 1935, 10, 525—534).—With low-carbohydrate diets an increase in the proportion of fat or protein lowers the glucose tolerance. Effects of other dietary variations are recorded.

A. G. P.

Effect of 1% of cod-liver oil on the rat with particular reference to the thyroid gland. C. B. FREUDENBERGER and F. W. CLAUSEN (J. Nutrition, 1935, 10, 549—555).

A. G. P.

Effect of choline on the weight of young rats. E. W. MCHENRY (J. Physiol., 1935, 85, 343—349).—Choline (I) and vitamin- $B_1$  exhibit a complementary effect on the gain in wt. of young rats. Rats not receiving (I) exhibit symptoms resembling those of vitamin- $B_1$  deficiency.

R. N. C.

Effect of deficient diets on the total ash, calcium, and phosphorus contents of bones. R. YEAGER and J. C. WINTERS (J. Nutrition, 1935, 10, 389—397).—In animals stunted (to maintain the same body-wt.) by calorie, protein, and lysine deficiency, the ash, Ca, and P of bones were > those of normal animals of the same wt. but < those of normal animals of the same age. Stunting by means of a low-salt diet caused very much lower bone vals. than in normal animals of the same wt. or age.

A. G. P.

Rats' milk and stomach contents of suckling rats. D. T. MAYER (J. Nutrition, 1935, 10, 343—350).—Recorded data indicate that suckling rats require a high-fat, low-carbohydrate diet. Although a large proportion of the calorific val. of rats' milk is derived from the fat, such a diet is not extremely ketogenic.

A. G. P.

Biological value of fresh milk and milk heated for short periods, in experiments on rat-feeding. H. HERTEL (Z. Immunitäts., 1935, 84, 321—327).—Milk heated for short periods is scarcely altered in its nutritional val. and vitamin content, whilst pasteurised milk differs considerably in biochemical composition. The short-period heated milk does not assure optimal or max. growth.

R. N. C.

Nutritive value of proteins for maintenance. S. MORRIS and N. C. WRIGHT (J. Dairy Res., 1935, 6, 289—302).—With maintenance rations containing min. proportions of protein a deficiency in lysine causes a decrease in urinary N characterised by an

MM

increase in  $\text{NH}_3$  and a decline in urea. Catabolism of body-tissue is high probably through excessive deamination with mild acidosis. Cystine deficiency has no effect.

A. G. P.

Utilisation of energy-producing nutriment and protein as affected by individual nutrient deficiencies. III. Effects of the plane of protein intake. E. B. FORBES, R. W. SWIFT, A. BLACK, and O. J. KAHLBURG (J. Nutrition, 1935, 10, 461—479).

A. G. P.

Effect of different percentages of protein in the diet on virgin rats. J. R. SLONAKER (Amer. J. Physiol., 1935, 113, 159—165).

R. N. C.

Replacement of protein [in cattle rations] by ammonium salts. S. V. FOMIN and V. I. DEMIN (Ukrain. Biochem. J., 1934, 7, No. 1, 133—143).—Replacement of proteins in the ration by urea and  $\text{NH}_4$  salts lowered the rate of growth.

CH. ABS. (p)

Proteins of foodstuffs. V. Contents of cystine and tryptophan. T. TOMIYAMA (J. Biochem. Japan, 1935, 22, 341—342).—The respective cystine, methionine (cf. A., 1934, 572), and tryptophan contents of the proteins from silk-worm pupæ (a), sardines (b), and soya beans (c) are: (a) 0.86, 2.97, 1.50; (b) 0.76, 3.14, 1.40; (c) 1.05, 1.96, 1.35%.

F. O. H.

Formation of histidine from arginine in incubating hens' eggs. T. KAMACHI (J. Biochem. Japan, 1935, 22, 199—202).—Injection of arginine (I) into incubating eggs is followed by an increase in the free histidine (II), whilst injection of (II) does not increase the level of (I).

F. O. H.

Origin of creatine from proteins and amino-acids. H. H. BEARD and T. S. BOGGESS (Amer. J. Physiol., 1935, 113, 647—653).—Creatine (I) in the muscles of rats fed on diets containing only 4% of protein is increased by re-feeding on a diet containing 25% of protein or 21% of glycine or glutamic acid. Total N, fat, and total solid in the muscles are scarcely changed. (I) is thus an exogenous catabolic product of proteins of  $\text{NH}_2$ -acids.

R. N. C.

Methionine content of food proteins. A. E. SCHARPENACK and G. P. JERJOMIN (Problems of Nutrition, Moscow, 1935, 4, No. 4, 11—16).—Casein has a very high methionine (I) but low cystine (II) content. Legume protein contains little (I), but some (II). Egg-yolk protein contains relatively large quantities of (I) and (II). Proteins of equal S content differ sharply in the character of their S compounds.

NUTR. ABS. (m)

Does bis- $\beta$ -aminoethyl disulphide (cystamine) promote growth in the rat limited to an inadequate intake of cystine and methionine? R. W. JACKSON and R. J. BLOCK (J. Biol. Chem., 1936, 113, 135—139; cf. A., 1933, 89; Mitchell, this vol., 102).—Cystamine does not promote growth of white rats maintained on a diet low in cystine and methionine.

F. A. A.

Availability of *dl*-amino-*N*-methylhistidine for growth. J. B. FISHMAN and A. WHITE (J. Biol. Chem., 1936, 113, 175—179).—*dl*- $\alpha$ -Chloro- $\beta$ -glyoxal-

inylpropionic acid was ineffective, and *dl*-amino-*N*-methylhistidine was effective, in producing a growth response in histidine-deficient rats. H. D.

**Influence of denervation on the carnosine content of muscles.** B. KOLDAEV and P. BUTKOV (Ukrain. Biochem. J., 1934, 7, No. 1, 63—67).—Section of the ischiatic nerve in one pad of a rabbit does not affect the carnosine (I) content of the gastrocnemius muscle. After rigor (I) probably decreases somewhat. CH. ABS. (p)

**Influence of fatigue on the glutathione content of muscle.** A. V. PALLADIN, S. BORSHKOVSKI, and L. PALLADINA (Ukrain. Biochem. J., 1934, 7, No. 1, 7—22).—Fatigued muscle shows an increase in oxidised glutathione (I). This is attributed to changed conditions of oxidation which lower the capacity of (I) to act as H acceptor. CH. ABS. (p)

**Aminohydroxy-acids and their degradation in the animal body.**—See this vol., 468.

**Formation of carbohydrate and fat from protein.** F. HÖLZL (Diss., München, 1933: Bied. Zentr., 1935, 6, A, 2).—A discussion. A. G. P.

**Effect of ingestion of cottonseed oil before and after hydrogenation on the composition of the body-fat of the rat.** J. M. SPADOLA and N. R. ELLIS (J. Biol. Chem., 1936, 113, 205—218).—The normal acids of rat adipose tissue were myristic, palmitic, stearic (I), palmitoleic (II), and oleic (III). Rats fed with a low-fat basal diet+ cottonseed oil deposited more (I) and (II) than those receiving partly hydrogenated oil or the basal diet alone. The deposition of linoleic acid  $\propto$  the amount fed and replaced (II) and (III). Small amounts of arachidonic acid were found in the fat after feeding with the oil. H. D.

**Digestion of fats from crude plant tissues: digestion of closed plant cells and their importance for physiology and pathology of digestion in man.** H. WEISS (Arch. Verdauungskr., 1935, 57, 42—45; Chem. Zentr., 1935, i, 3565).—The fat of the uninjured cells is digested by the intestinal lipases in the mouse. R. N. C.

**Carotenoids and oxidation of lipins.** J. VERNE (Compt. rend. Soc. Biol., 1936, 121, 609—610).—Only those lipins of skin or adrenal sections that do not give a positive Feulgen-Verne reaction can be stained with carotenoids (I); autoxidation renders the reaction positive, but prevents staining. (I) protect the lipins against autoxidation. R. N. C.

**Can intact monoglycerides be resorbed?** G. ROSENTHAL and H. TRAUTWEIN (Ber. Verh. sächs. Akad. Wiss., math.-phys. Kl., 1934, 86, 325—338).—The depancratised dog resorbs monoglycerides (I) better than triglycerides, probably because the (I) are absorbed without previous cleavage on account of their small solubility in  $H_2O$  or of their capacity to form emulsions; both these properties facilitate cleavage by intestinal lipases. Hydrolysis is further favoured by the surface activity of the (I), through which they are more readily adsorbed on the lipases and more quickly saponified. R. N. C.

**Fat metabolism. XVI. Biological degradation of fatty acids, esters, and fats to dicarboxylic acids.** B. FLASCHENTRÄGER and K. BERN-

HARD (Z. physiol. Chem., 1936, 238, 221—232; cf. A., 1935, 1151).—Coconut oil and cooking fat (20% butter), if given in sufficient amount, are degraded in the dog, yielding small amounts of sebacic (I) and suberic acid. The Me and Et esters of the  $C_9$ — $C_{12}$  monocarboxylic acids, given with fat, yield the corresponding dicarboxylic acids. Of the Na salts of the  $C_6$ — $C_{12}$  and  $C_{14}$ ,  $C_{16}$ , and  $C_{18}$  monocarboxylic acids only octoic, nonoic, and decoic acids yield dicarboxylic acids. The behaviour of the Me and Et esters of these monocarboxylic acids is analogous. (I), even when given in very small amounts, passes chiefly unchanged (partly  $\beta$ -oxidised) into the urine. The degradation of monocarboxylic acids probably proceeds more rapidly than does that of the dicarboxylic acids and consequently  $\beta$ - rather than  $\omega$ -oxidation predominates in the organism. W. McC.

**Fat metabolism in fowls: practical significance.** E. T. HALNAN and E. M. CRUICKSHANK (Proc. 5th World's Poultry Congr. Rome, 1933, 2, 612—619).—Pullets at 15 weeks of age commence to store more fat than cockerels, the difference increasing with advancing maturity. The  $Et_2O$ -sol. matter in the blood of laying hens is  $>$  that in the blood of cockerels. The I val. of depôt fat reflects that of food fat. Ingestion of unsaturated acids, e.g., hemp oil, causes an increase in unsaturated acids on egg-yolk fat. CH. ABS. (p)

**Deuterium as an indicator in fat metabolism.** B. CAVANAGH and H. S. RAPER (Nature, 1936, 137, 233—234).—By the use of linseed oil containing D for investigating the absorption of fatty acids in the rat, it is shown that lipins of the liver and kidney take up the D-containing fatty acids. L. S. T.

**Effect of liver feeding on the "fat" content of the liver.** A. W. BEESTON and H. WILKINSON. (Biochem. J., 1936, 30, 121—126).—Rats fed on a diet containing chiefly dried liver developed fatty livers (A., 1934, 104); cholesteryl esters (I) rose to 1.8% and glycerides (II) to 2%. 214 mg. of extra choline (III) added to the diet daily had no influence on the % of (I) but lowered that of (II). Using  $EtOH$ -extracted livers with added beef dripping gave vals. for (I) and (II) of 0.45 and 1.67%, respectively; addition of the extracted cholesterol (IV) to the diet raised the vals. to 3.62 and 3.19% so that the fatty liver production is due to (IV) in the diet.  $H_2O$ -extracted liver gave the same results as unextracted liver. Inclusion of extra (IV) in the diet produced increased fat deposition, whilst replacing the dried by raw liver or adding (III) had little effect. H. D.

**Dietary prevention of fatty livers. Triethyl- $\beta$ -hydroxyethylammonium hydroxide.** H. J. CHANNON and J. A. B. SMITH (Biochem. J., 1936, 30, 115—120).—Triethyl- $\beta$ -hydroxyethylammonium hydroxide (I) (aurichloride, m.p. 225°), prepared from  $NEt_3$  and  $CH_2Cl-CH_2-OH$ , when fed to rats on a fatty liver-producing diet caused an inhibition of fat accumulation rather  $<$  that of choline. Large individual variations in fat accumulation occurred which were not associated with food intake; the inhibitory action of (I) on does was  $>$  on bucks. H. D.

**Carbohydrate and fat metabolism during development of *Hynobius* eggs.** M. TAKAMATSU (Z. physiol. Chem., 1936, 238, 96—98).—The glycogen, fat, and cholesterol contents of the embryos of *H. nebulosus* eggs decrease with development. The fat is almost entirely sol. in both EtOH and Et<sub>2</sub>O.

R. S. C.

**Utilisation of inulin for growth by the young white rat.** A. BENDAÑA and H. B. LEWIS (J. Nutrition, 1935, 10, 507—515, 578).—With rats receiving a calorie-deficient diet utilisation of inulin was < that of sucrose or fructose. Inulin cannot serve as the sole source of carbohydrates for rats.

A. G. P.

**Do the phosphorus and glycogen contents of frog muscle run parallel?** A. MOSCHINI (Bull. Soc. Chim. biol., 1936, 18, 160—164).—The changes in the P and glycogen content of frog muscle caused by injection of glucose into normal animals and those with muscles atrophied by fasting, by section of the sciatic nerve, and by pancreatectomy do not run parallel. A lowering of the P content is always associated with functional disturbance.

A. L.

**Absorption and utilisation of carbohydrates [by animals].** H. B. PIERCE (J. Nutrition, 1935, 10, 689—716).—A review.

A. G. P.

**Fœtal carbohydrate metabolism following adrenalectomy, insulin, and glucose experiments on the mother.** E. L. COREY (Amer. J. Physiol., 1935, 113, 450—454).—Adrenalectomy and administration of insulin in the pregnant rat cause a fall of liver-glycogen in both mother and fœtus, whilst glucose (I) increases it. Cortical hormone is without effect. Placental and fœtal muscle-glycogen are relatively unaffected; the latter shows a slight rise with (I).

R. N. C.

**Carbohydrate metabolism of gut muscle.** B. N. PRASAD (J. Physiol., 1935, 85, 239—248).—The isolated muscle contains only about 0.25% of carbohydrate available for glycolysis; it oxidises about 1 mg. of carbohydrate per g. per hr. in presence of O<sub>2</sub>. In presence of glucose (I) it produces lactic acid under aerobic or anaërobic conditions; even in oxygenated Ringer's solution the deeper portions of the muscle probably receive an inadequate O<sub>2</sub> supply. Glycolysis under anaërobic conditions takes place at about 2 mg. of (I) per g. per hr.; it is inhibited by CH<sub>3</sub>I·CO<sub>2</sub>Na and increased by electric stimulation.

R. N. C.

**Utilisation of sugars and polyhydric alcohols by the adult blowfly.** G. FRAENKEL (Nature, 1936, 137, 237—238).—The utilisation by *Calliphora erythrocephala* of numerous carbohydrates and polyhydric alcohols is summarised. The results indicate the presence of several enzymes (enumerated) in the gut of the fly.

L. S. T.

**Animal calorimetry. XI. Specific dynamic action of carbohydrate.** Z. ASZÓDI and J. PÉLYI (Biochem. Z., 1936, 283, 393—414).—The sp. dynamic action of carbohydrate on administration of large amounts of sugar is > that of fat but with small amounts is not related quantitatively to the amount of sugar used. In presence of carbohydrate

reserves, these small amounts are not therefore immediately burnt. The elimination of heat on feeding carbohydrate does not synchronise with the O utilisation.

P. W. C.

**Acidosis, alkalosis, and carbohydrate metabolism. Influence of acid- and base-producing diets.** C. MORI (J. Biochem. Japan, 1935, 22, 437—446).—The assimilation of sugar by rabbits (as indicated by the change in blood-sugar after ingestion of glucose) on a diet producing acidosis is > that with a diet producing alkalosis.

F. O. H.

**Influence of calcium on intestinal absorption.** E. J. McDougall (J. Physiol., 1935, 85, 109—116).—Absorption of isotonic glucose, xylose, and sorbose solutions injected into the small intestine in rats is not affected by a diet producing low serum-Ca.

R. N. C.

**Mechanism of the suppression of ammonio-genesis in muscle by pyruvic acid.** J. K. PARNAS, B. SOBCEK, and W. MEJBAUM (Compt. rend. Soc. Biol., 1936, 121, 701—704).—NH<sub>3</sub> production is suppressed by AcCO<sub>2</sub>H (I) more rapidly in presence of hexose diphosphate, which accelerates NH<sub>3</sub> production *per se*. (I) probably reduces phosphoglyceraldehyde to phosphoglyceric acid, which is then transformed into phosphopyruvic acid. The latter reacts with NH<sub>3</sub> and adenylic acid to form adenosinetriphosphoric acid.

R. N. C.

**Transformation of adenosinetriphosphoric acid in muscle. II. Relation between dephosphorylation of the acid, production of ammonia, and degradation of creatinephosphoric acid during muscular activity.** D. FERDMANN and O. FEINSCHMIDT (Biochem. Z., 1936, 284, 63—71; cf. A., 1935, 778).—In the frog, muscular activity results in degradation of adenosinetriphosphoric (I) and creatinephosphoric acid (II) with production of H<sub>4</sub>P<sub>2</sub>O<sub>7</sub> and H<sub>3</sub>PO<sub>4</sub>, respectively. During recovery of fatigued muscle, (I) and (II) are resynthesised with disappearance of H<sub>4</sub>P<sub>2</sub>O<sub>7</sub> and H<sub>3</sub>PO<sub>4</sub>, the extent of resynthesis depending on the length of the period of recovery and being almost complete in 15 min. The adenylic acid produced by dephosphorylation of (I) is deaminated during activity and reaminated during recovery.

W. McC.

**Effects of cod-liver oil and wheat germ on the retention of iron, nitrogen, phosphorus, calcium, and magnesium during human pregnancy.** C. M. COONS and R. R. COONS (J. Nutrition, 1935, 10, 289—310).—Addition of wheat germ to a basal diet improved the retention of Fe and N, the effect being due to the mineral rather than to the org. contents. Cod-liver oil enhanced the action of wheat germ. Increased retention of Ca, Mg, and P due to feeding cod-liver oil is small and irregular.

A. G. P.

**Spectrum analysis of hen-eggs and chick-tissues.** W. F. DREA (J. Nutrition, 1935, 10, 351—355).—Al, Ba, Ca, Cu, Fe, Mg, P, K, Rb (?), Si, Na, Sr, Ti, and V pass from food or H<sub>2</sub>O into the egg and thence into blood and tissues of the chick. Mn and Zn are absent from chicks' blood. Al, Ba, Cu, Si, Sr, Ti, and Zn are uniformly distributed among the tissues. Ba, Fe, Sr, and V are more conc. in hens'

blood and/or egg than in the food. B, F, and Ag are unnecessary or harmful to chicks. Cr, Pb, and Mo occur in hens' blood in amounts corresponding to those in the food but are not regularly present in eggs. When present in chicks, Mo accumulates in the liver, Pb in lungs, and Cr in brain and eye. Mn occurs in yolks but not in whites or shells, and in chicks accumulates in the liver. A. G. P.

**Chemistry of cephalopod embryos.** T. KAMACHI (Z. physiol. Chem., 1936, 238, 91—95).—The Ca, Mg,  $\text{SO}_4$ ,  $\text{NH}_2$ , and enzyme contents of the embryo increase at the expense of the residue during development of the eggs of *Loligo bleekeri*, Kefirstein, but the  $\text{PO}_4$  and Cu contents remain unchanged; the enzymes present resemble qualitatively those of other eggs. R. S. C.

**Toxicity and rate of disappearance of intracisternally injected calcium salts in the dog.** M. F. MASON, and H. RESNIK (J. Pharm. Exp. Ther., 1936, 56, 53—59).—Aq.  $\text{CaCl}_2$ , Ca gluconate and lactate containing 0.25 mg. of Ca per kg. body-wt. are injected into dogs without producing toxic action. Larger doses cause respiratory depression, 0.4 mg. of Ca per kg. being the lethal dose. Simultaneous injection of Mg does not increase the Ca tolerance. A. L.

**Influence of nutrition on metabolism during work. IV. Calcium.** F. BRUMAN and F. JENNY (Deut. Arch. klin. Med., 1935, 177, 527—543; Chem. Zentr., 1935, ii, 243).—The effects of Ca and K on metabolism were antagonistic. G. H. F.

**Calcium as a factor in the nutritional improvement of health.** H. C. SHERMAN (Proc. Nat. Acad. Sci., 1936, 22, 24—26).—A discussion of recent work. A. G. P.

**Effects of increasing the calcium content of a diet in which calcium is one of the limiting factors.** H. C. SHERMAN and H. L. CAMPBELL (J. Nutrition, 1935, 10, 363—371).—Addition of Ca to the diet improved food utilisation and the general development of rats. A. G. P.

**Calcium and phosphorus needs of pre-school children.** A. L. DANIELS, M. K. HUTTON, E. M. KNOTT, O. E. WRIGHT, and M. FORMAN (J. Nutrition, 1935, 10, 373—388).—The requirements are 45—50 mg. of Ca (with adequate vitamin-D) and 60—70 mg. of P per kg. A. G. P.

**Calcium and phosphorus metabolism in chick embryos.** T. KAMACHI (J. Biochem. Japan, 1935, 22, 189—197).—Injection of  $\text{CaCl}_2$ ,  $\text{Na}_2\text{HPO}_4$ , or org. Ca- $\text{PO}_4$  preps. (I) into incubating eggs diminishes the Ca content of the embryo but not that of the allantoic fluid; the effect is probably due to inhibition of Ca mobilisation from the shell. (I), but not  $\text{Na}_2\text{HPO}_4$ , increases the P content of the embryo. F. O. H.

**Calcium and phosphorus requirements of growing turkeys.** F. E. MUSSEHL and C. W. ACKERSON (Proc. 5th World's Poultry Congr. Rome, 1933, 2, 664—667).—A factor other than the Ca:P ratio of the diet influences Ca and P assimilation. The acid:base ratio of the entire ration probably has an important effect. In the absence of vitamin-D

and ultra-violet energy, poultts receiving the higher levels of Ca ( $\text{CaCO}_3$ ) were better able to adjust themselves to vitamin limitation. The Ca and P requirements vary with the growth rate, which is influenced by the quality and quantity of protein and the supply of vitamins other than -D.

CH. ABS. (p)

**Changes in lime content between various parts of the hen's egg during incubation.** A. CAZANIGA (Proc. 5th World's Poultry Congr. Rome, 1933, 2, 444—449).—The shell-Ca diminished rapidly from the 13th day of incubation. In the egg contents vals. increased subsequently. CH. ABS. (p)

**Experimental sodium chloride deficiency in man.** R. A. McCANCE (Proc. Roy. Soc., 1936, B, 119, 245—268).—In man, a severely limited intake of NaCl (about 40 mg. of Na, 200 mg. of Cl, daily), accompanied by sweating, but without limitation of  $\text{H}_2\text{O}$  intake, causes a loss of at least 25—30% of the extra-cellular Na and Cl. The N balance becomes negative, and the blood-urea rises. The body appears to react partly by allowing the total vol. of body fluids to fall, partly by allowing their osmotic pressure to fall. F. A. A.

**Acidosis as a factor of fatigue in dogs.** F. W. SCHLUTZ, M. MORSE, and A. B. HASTINGS (Amer. J. Physiol., 1935, 113, 595—601).—Alkalosis from  $\text{NaHCO}_3$  reduces, whilst acidosis from  $\text{NH}_4\text{Cl}$  favours, the capacity of dogs for exercise;  $\text{NaHCO}_3$  promotes lactic acid formation, whilst  $\text{NH}_4\text{Cl}$  depresses it. Acidosis accompanying exercise is not a causal factor of fatigue. R. N. C.

**Effect of sodium fluoride on the basal metabolism of the rat under several experimental conditions.** P. H. PHILLIPS, H. E. ENGLISH, and E. B. HART (Amer. J. Physiol., 1935, 113, 441—449).—Normal basal metabolism in rats is not affected by feeding with NaF, but when previously raised by thyroid it exhibits a sharp and rapid rise. KI alone causes a temporary reduction, which is unaffected by simultaneous administration of NaF. R. N. C.

**Metabolism in the rat of the naturally-occurring arsenic of the shrimp as compared with arsenic trioxide.** E. J. COULSON and R. E. REMINGTON and K. M. LYNCH (J. Nutrition, 1935, 10, 255—270).—In the shrimp As occurs in complex combination from which it cannot be liberated in the animal organism. Following the digestive process in rats shrimp-As appears in a sol. form and is eliminated through the kidneys; it is retained only to a very small extent. No evidence of toxicity was obtained. A. G. P.

**Physiological and clinical rôle of bromine metabolism.** L. A. JACOBSEN (Presse méd., 1935, 43, 452—454; Chem. Zentr., 1935, i, 3565).—A review. R. N. C.

**Human iodine balance.** V. V. COLE and G. M. CURTIS (J. Nutrition, 1935, 10, 493—506).—The combined urine- and stool-I may account for < 50% of the I intake in some cases. The output of I was fairly uniform for an individual on a monotonous diet. Increased faecal I occurred in cases of hyperthyroidism. A. G. P.

**Iron metabolism.** E. NOLTE (Arch. Pharm., 1936, 274, 107—110).—The liver, lung, and kidney of a goat kept during 5 months on a diet containing a liver-Fe-protein adsorbate (ferripan) ( $\approx 0.26$  g. Fe per diem) contain considerably more Fe than the same organs of a goat maintained on an Fe-free diet. The Fe content of the blood and milk is the same in both cases. H. B.

**Iron metabolism of pre-school children.** L. ASCHAM (J. Nutrition, 1935, 10, 337—342).—Retention of Fe by children of 4—6 years averaged 0.07 mg. with an intake of 0.59 mg. A. G. P.

**Iron requirements of normal adults.** G. E. FARRAR, jun., and S. M. GOLDBAMER (J. Nutrition, 1935, 10, 241—254).—The Fe requirement is normally  $> 5$  mg. daily. Normal urine contains 0.02 mg. of Fe per 100 c.c. A. G. P.

**Nitrogen metabolism in soya bean-feeding of horses.** U. I. LISTOVNISCHA and M. F. GULUII (Ukrain. Biochem. J., 1934, 7, No. 1, 153—161).—Feeding of soya beans increases N metabolism. Urinary N (daily excretion) increases and the urea: total N ratio declines through increase in other N constituents, especially  $\text{NH}_3$ . There is increased excretion of creatinine owing to higher endogenous protein metabolism. CH. ABS. (p)

**Metabolism of women during the reproductive cycle.** VI. Continuous nitrogen utilisation of a multipara during pregnancy, parturition, puerperium and lactation. H. A. HUNSCHER, F. C. HUMMELL, B. N. ERICKSON, and I. G. MACY (J. Nutrition, 1935, 10, 579—597).—N balances over a period of 8 months are recorded and discussed (cf. A., 1933, 304). A. G. P.

**Nitrogen and sulphur metabolism in supra-renalectomised rats.** M. SANDBERG and D. PERLA (J. Biol. Chem., 1936, 113, 35—41).—There was no change in the excretion of uric acid, faecal N and S, and in Cu and Fe metabolism. There was marked creatinuria and an increase in urea, urinary N and S, and neutral S. The % of  $\text{SO}_4^{--}$  decreased slightly. J. N. A.

**Effect of sulphur in the diet on the growth and wool production of sheep.** Nutritive value of some vegetable oils in N. China.—See B., 1936, 218.

**Food value of ethyl alcohol.** H. H. MITCHELL (J. Nutrition, 1935, 10, 311—335, 460).—The energy of ingested EtOH is largely available for physiological purposes. Added to a milk diet EtOH induces more rapid growth, a greater retention of N and fat, and improved digestibility of the basal diet. Sucrose (I) has a relatively greater growth-promoting action, more available energy, and no effect on the digestibility of the basal diet. (I) increases the faecal excretion of metabolic products, but EtOH has no action. A. G. P.

(A) Clearance, extraction percentage, and estimated filtration of sodium ferrocyanide in the mammalian kidney: comparison with inulin, creatinine, and urea. (B) Distribution of ferrocyanide, inulin, creatinine, and urea in

blood: effect on significance of their extraction percentages. D. D. VAN SLYKE, A. HILLER, and B. F. MILLER (Amer. J. Physiol., 1935, 113, 611—628, 629—641).—(A) The plasma clearances and extraction % of  $\text{Na}_4\text{Fe}(\text{CN})_6$  (I), inulin (II), and creatinine (III) in the dog are approx. equal; they are independent of plasma concn. The clearance of urea is about 57% of those of the above substances, and is also independent of plasma concn.

(B) (I) and (II) injected intravenously in the dog are not absorbed into the erythrocytes, but remain in the plasma. (III) enters the corpuscles very slowly, so that it is not withdrawn from them as the blood passes through the kidneys, whilst urea diffuses very readily into the cells, and is therefore withdrawn from them in the kidneys. R. N. C.

**Excretion of phenol-red by the dog.** J. A. SHANNON (Amer. J. Physiol., 1935, 113, 602—610).—Phenol-red (I) excretion is  $>$  insulin (II) excretion at low plasma-(I) levels, but the (I)/(II) excretion ratio falls as the level increases. The depression of (I) clearance as the level is raised is reversible. The ratio is unaffected by phloridzin. R. N. C.

**Metabolism of orally administered citric acid.** C. C. SHERMAN, L. B. MENDEL, and A. H. SMITH [with M. C. TOOTHILL] (J. Biol. Chem., 1936, 113, 265—271).—Only 0.7% of orally administered citric acid appeared in the urine of the dog, none appeared in the faeces, whilst the increased blood-content was maintained for 3—7 hr. The renal threshold was 2.2—6.0 mg. per 100 c.c. H. D.

**Citric acid formed in animal metabolism.** C. C. SHERMAN, L. B. MENDEL, and A. H. SMITH [with M. C. TOOTHILL] (J. Biol. Chem., 1936, 113, 247—263).—The quantity of citrate (I) excreted by men  $\propto$  urinary  $p_{\text{H}}$ ; addition of  $\text{NaHCO}_3$  to a low-citrate diet increases the excretion of (I); in dogs the increase is favoured by replacement of the dietary caseinogen by sucrose. Ingestion of the diet produced an increased excretion of (I) which was not due solely to a raised blood-(I) or diuresis. H. D.

**Curves of sodium formaldehydesulphoxylate in the blood after intravenous or intragastric administration.** E. HUG (Compt. rend. Soc. Biol., 1936, 121, 579—581).—The compound disappears rapidly from the plasma of the dog after intravenous injection, a large part being excreted by the kidneys. The relatively low plasma concn. after intragastric administration  $\propto$  the quantity given. The curve reaches its max. in 2—8 hr. R. N. C.

**Elimination of sodium formaldehydesulphoxylate by the digestive secretions.** T. C. MINNHAAR (Compt. rend. Soc. Biol., 1936, 121, 581—582).—In the dog the compound is eliminated in very small quantities in the saliva, bile, and pancreatic and intestinal juices. R. N. C.

**Degradation of mescaline and similar substances in the body.** K. H. SLOTTA and J. MÜLLER (Z. physiol. Chem., 1936, 238, 14—22).—Mescaline (I), given orally, is excreted mainly as  $(\text{OMe})_3\text{C}_6\text{H}_2\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$  (II) in the urine of rabbits and dogs. Instead of (II), human urine gives a OMe-rich oil, a mixture of probably two substances,

which on hydrogenation ( $\text{PtO}_2$ ) absorbs  $3\text{H}_2$  and gives a substance,  $\text{C}_9\text{H}_{14}\text{O}_2\text{N}\cdot\text{OMe}$ , cryst. (no picrate, auri- or platini-chloride). (II) is recovered in good yield unchanged from the urine of dogs or rabbits to which it is fed, and has no physiological effect on these animals or man.  $3:4:5\text{-(OMe)}_3\text{C}_6\text{H}_2\cdot\text{CHO}$  is recovered from urine as the acid, but  $\beta\text{-}3:4:5\text{-trimethoxyphenylethyl alcohol}$  (III) yields a N-containing degradation product. (I) has very little effect on schizophrenic patients, who are, however, profoundly affected by  $2:3:4\text{-(OMe)}_3\text{C}_6\text{H}_2\cdot[\text{CH}_2]_2\cdot\text{NH}_2$ , which is innocuous to healthy men.  $3:4:5\text{-(OMe)}_3\text{C}_6\text{H}_2\cdot\text{COCl}$  and  $\text{CH}_2\text{N}_2$  give  $3:4:5\text{-trimethoxy-}\omega\text{-diazoacetophenone}$ , m.p.  $103^\circ$  (and some Cl-ketone), which yields  $3:4:5\text{-trimethoxyphenylacetamide}$ , m.p.  $125^\circ$ , hydrolysed by hot  $\text{KOH}\cdot\text{MeOH}$  to (I), m.p.  $121^\circ$ . (I) and  $\text{HNO}_2$  afford (III), b.p.  $95\text{--}135^\circ/0\cdot01\text{ mm.}$  (*p*-nitrobenzoate, m.p.  $100^\circ$ ). R. S. C.

**Degradation of dimethylaniline and its oxide in the animal body.** F. HORN (Z. physiol. Chem., 1936, 238, 84—90).— $\text{NPhMe}_2$  is not converted by dogs into  $\text{NPhMe}_2\text{O}$ . Both compounds are converted, at least partly, into  $o\text{-OH}\cdot\text{C}_6\text{H}_4\cdot\text{NH}_2$ . The toxic symptoms of  $\text{NPhMe}_2$  include methæmoglobin formation. R. S. C.

**Tissue cultures exposed to the influence of a magnetic field.** R. PAYNE-SCOTT and W. H. LOVE (Nature, 1936, 137, 277).—Exposure to magnetic fields of 5000 gauss produced no observable change in the growth of cells from the heart of chick embryos cultivated *in vitro*. A slight tendency to protoplasmic disintegration in some of the resting cells was observed in certain exposed cultures. L. S. T.

**Changes in the blood-fluid of *Scyllium canicula* exposed to continuous current, when the branchial region is close to the anode.** E. A. PORÅ (Compt. rend. Soc. Biol., 1936, 121, 503—504).—The increases of blood-osmotic pressure and  $\text{-Ca} \propto I$ , but are  $<$  those obtained when the branchial region adjoins the cathode, as are also the variations of blood- and serum-Cl and  $\text{-Na}$ , whilst the increases of proteins and corpuscular Cl and the fall of the alkaline reserve are higher. The fall of  $\kappa$  is the same in both cases. The increases of inorg. salts and org. substances are  $>$  the corresponding losses in the muscles. R. N. C.

**Changes in the blood-fluid of the male *Scyllium canicula* produced by continuous electric current.** E. A. PORÅ (Compt. rend. Soc. Biol., 1936, 121, 507—508).—Passage of current for 12 hr. increases muscle- $\text{H}_2\text{O}$  at the expense of the blood. Inorg. salts in the muscles increase considerably, possibly through penetration of salts from the external medium, whilst org. substances fall in the muscles and rise in the serum. The alkaline reserve increases, whilst blood-Cl falls. R. N. C.

**Changes in the blood-fluid of the male *Scyllium canicula*, produced by an opposing continuous electric current in the external medium.** E. A. PORÅ (Compt. rend. Soc. Biol., 1936, 121, 660—662; cf. preceding abstract).—The blood loses  $\text{H}_2\text{O}$  without a corresponding gain in the muscles. Inorg. salts increase in both blood and muscles, but org.

substances pass from the muscles to the blood. Blood-, serum-, and corpuscular-Cl,  $\text{-Na}$ ,  $\text{-proteins}$ , the alkaline reserve, and  $\kappa$  are all increased, whilst  $\text{-Ca}$  falls. R. N. C.

**Effect of ultra-violet radiation on lens protein in the presence of salts and the relation of radiation to industrial and senile cataract.** J. H. CLARK (Amer. J. Physiol., 1935, 113, 538—547).—Ultra-violet irradiation of solutions of lens proteins in aq.  $\text{NaCl}$ ,  $\text{KCl}$ , and  $\text{CaCl}_2$  at  $p_{\text{H}}$  6·0—7·2 and  $4^\circ$  denatures the proteins but produces no increase of opacity except when  $\text{CaCl}_2$  is present. No increase is found at  $p_{\text{H}}$  7·8, whilst the increase is general at  $p_{\text{H}}$  5·4. Opacity is not increased by heating to  $40^\circ$  at  $p_{\text{H}}$  7·2 without irradiation, but after irradiation it is increased considerably in all solutions containing  $\text{Ca}$ ;  $\text{Na}$ , but not  $\text{K}$ , exerts a restraining action. Light-coagulation probably consists of denaturation of the proteins followed by pptn. through  $\text{Ca}$ ; senile cataract may be due to accumulation of denatured protein in the lens together with increased blood- $\text{Ca}$ , whilst exposure to intense radiant heat is responsible for cataract in metal and glass workers. R. N. C.

**Factors concerned in the arrest of contraction in an ischemic myocardial area.** R. TENNANT (Amer. J. Physiol., 1935, 113, 677—682).— $\text{NaCN}$  and  $\text{KCl}$ , but not  $\text{CH}_3\text{I}\cdot\text{CO}_2\text{Na}$ , arrest contraction, which is also arrested by perfusion of a ventricular zone in the normal heart with  $\text{Na}$  lactate in buffered blood-Locke's solution. R. N. C.

**Adrenaline glycæmia in the dog submitted to slow continuous intravenous injections of alkaline mineral water.** E. CHABROL and J. SALLET (Compt. rend. Soc. Biol., 1936, 121, 733—735).—Large quantities of 0·7% aq.  $\text{NaHCO}_3$  reduce considerably the blood-sugar and its response to subsequent injection of adrenaline. R. N. C.

**Effect of buffered phosphate solutions on a thin layer of living vascular tissue, in moist chambers introduced into the rabbit's ear.** R. G. ABELL (Anat. Rec., 1935, 64, 51—73). R. N. C.

**Reversible loss of the all-or-none response in cold-blooded hearts treated with excess potassium.** G. H. ZWIKSTER and T. E. BOYD (Amer. J. Physiol., 1935, 113, 560—567). R. N. C.

**Deposition of strontium salts in hypertrophic cartilage *in vitro*.** R. ROBISON, K. A. O. LAW, and A. H. ROSENHEIM (Biochem. J., 1936, 30, 66—68).—The deposition *in vitro* of  $\text{Sr}$  salts in hypertrophic cartilage (dissected away from all calcified tissue) by immersion in solutions containing  $\text{Sr}^{++}$  (spectroscopically pure),  $\text{PO}_4^{---}$ , and  $\text{CO}_3^{--}$  is confirmed, the deposits being shown by spectrum analysis to consist largely of a  $\text{Sr}$  phosphate or carbonatophosphate. P. W. C.

**Function of fluorine in the human organism.** L. MICHAELIS (Klin. Woch., 1935, 14, 94—95).—Theoretical. R. N. C.

**Iodine injuries with particular reference to "complete salts" injuries.** I. MÜHE (Deut. Arch. klin. Med., 1935, 177, 345—367; Chem. Zentr., 1935, i, 3949). R. N. C.

**Action of iodine on basal exchange in intestinal closure.** J. GLATZEL (Wien. med. Woch., 1935, 85, 397—400; Chem. Zentr., 1935, i, 3565).—The high basal exchange in rectal cancer and artificial intestinal closure is reduced to normal in 7 days by Lugol's I solution. R. N. C.

**Selenium in [animal] nutrition.** H. A. SCHNEIDER (Science, 1936, 83, 32—34).—Growth effects are described for rats receiving up to 70 p.p.m. of Se as  $\text{Na}_2\text{SeO}_3$  with a normal diet. L. S. T.

**Effect of sulphur on the weight and adrenaline content of the adrenal capsule and on the vasoconstrictor action of blood-serum.** M. MITANI (Folia Endocrinol. Japon., 1933, 8, 104).—Intramuscular injection of large doses of S lowered the wt. and adrenaline content of the adrenals. Continuous small dosage of S produced a similar effect, but the wt. of the capsules increased.

CH. ABS. (*p*)

**Sulphur-mercury compounds and their action on the blood.** L. LIACI (Arch. Farm. speriment., 1933, 56, 372—381; Chem. Zentr., 1935, i, 3952).—Injection of a S-Hg compound in rabbits causes slight modifications of blood-sugar, increases of erythrocytes and leucocytes, and decrease of resistance of erythrocytes to hypotonic NaCl solutions. Blood-Ca and hæmoglobin are unaffected. R. N. C.

**Chemotherapeutic activity of compounds of arsenic with albumin breakdown products rich in sulphur.** W. A. COLLIER and M. KRAUSE (Z. Hyg., 1935, 117, 190—195). R. N. C.

**Physiological action of zinc in animals.** G. BERTRAND (Bull. Soc. Chim. biol., 1936, 18, 213—224).—A review. A. L.

**Pharmacology of ethyl alcohol.** I. Comparison of grain and synthetic alcohols. II. Correlation of the local irritant, anæsthetic, and toxic effects of three potable whiskies with their alcohol content. O. W. BARLOW [with A. J. BEAMS and H. GOLDBLATT] (J. Pharm. Exp. Ther., 1936, 56, 117—146).—The toxic and physiological effects of synthetic and grain EtOH are indistinguishable. The irritant and toxic effects of whisky are > those due to its EtOH content. Administration of synthetic or grain EtOH or whisky to rats in concns. equiv. to 7.5% of EtOH as the sole source of fluid had no effect on growth, but at concns. of 15% growth was retarded. Certain differences are observed in their actions on the stomach and intestine as between synthetic or grain EtOH and whisky. W. O. K.

[Action of] carbonyl chloride [on the blood].—See this vol., 301.

[Physiological] effect of acetic and substituted acetic esters of borneol. H. TSUJI (Tôhoku J. Exp. Med., 1934, 24, 374—379). CH. ABS. (*p*)

**Action of benzene in pregnancy.** G. BARZILAI (Boll. Soc. ital. Biol. speriment., 1933, 8, 1388—1392).—Pregnant female mice are less resistant to narcosis from  $\text{C}_6\text{H}_6$  in the inspired air. The effect is most noticeable at a concn. of 35.43 mg. of  $\text{C}_6\text{H}_6$  per litre of air; with < 26 mg. per litre acute narcosis does not occur. R. N. C.

**Anthelmintic studies on hydroxyalkylbenzenes.** VI. Alkyl polycyclic phenols. VII. Halogenated phenols. VIII. Phenolic ketones, ethers, and esters, and organic acids. P. D. LAMSON, R. W. STOUGHTON, and A. D. BASS (J. Pharm. Exp. Ther., 1936, 56, 50—52, 60—62, 63—68).—VI. The *in-vitro* ascaricidal properties of various polycyclic phenols are not significantly increased by introduction of alkyl groups.

VII. High activity is shown by *p*-chlorocarvacrol, 4-chloro-2-hexyl-phenol and -2-heptyl-phenol. 2:4:6-Tribromo-phenol and -resorcinol are, however, inactive.

VIII. Of > 100 phenolic ketones, ethers, esters, and acids, none shows marked *in vitro* ascaricidal activity. Some monoethers of dihydric phenols are active, but too toxic for use. A. L.

**Acid-base changes in the serum of the dog associated with the hyperthermia of dinitrophenol administration.** E. MUNTWYLER, V. C. MYERS, W. H. DANIELSON, and C. ZORN (Amer. J. Physiol., 1935, 113, 186—192).—Oral administration of sublethal doses of 2:4-dinitrophenol (I) frequently increases serum-Cl and decreases  $\text{HCO}_3^-$ . Total bases (II) are somewhat variable, depending on the quantity of (I) given;  $p_{\text{H}}$  remains within normal limits, but tends to fall slightly from the control level with large doses of (I). Subcutaneous injection of (I) lowers Cl and  $\text{HCO}_3^-$ ; (II) are decreased by sublethal and increased by lethal doses, the undetermined acid concn. being increased in both cases: the  $p_{\text{H}}$  remains fairly const. R. N. C.

**Mechanism of the stimulating action on metabolism of dinitro-compounds.** Acetaldehyde, dihydroxyacetone, and glutathione as antidotes. H. HANDOVSKY, H. CASIER, and C. SCHEPENS (Arch. int. Pharmacodyn., 1935, 50, 397—446).—Dinitrocyclopentylphenol (I) ("pentyl") is the most stimulating and least toxic of all the nitro-derivatives. An activator for dinitro-derivatives which varies in its ease of extractability exists in muscle. The stimulation of metabolism *in vitro* is attributed to a respiratory enzyme differing from the normal cellular respiratory enzymes in being cryolabile. (I) added to muscle diminishes its glutathione (II) content, and, in living pigeons, intravenously (II) prevents the hyperthermia which follows (I) injection. A similar inhibition is shown by dihydroxyacetone and MeCHO. *In vitro*, the destruction of MeCHO by muscular tissue is increased by addition of (I); hence MeCHO takes part in the oxido-reduction processes affected. NUTR. ABS. (*m*)

**Comparative actions of cardiazole and coramine on the respiratory centre of man.** I. Subcutaneous injection. H. STEININGER and E. GAUBATZ (Klin. Woch., 1935, 14, 159—160).—Cardiazole is the more active compound. R. N. C.

**Action of large quantities of glucose in prolonged intravenous infusion.** E. BAUER and H. KNÜPPER (Ber. Verh. sächs. Akad. Wiss. math.-phys. Kl., 1934, 86, 339—350).—The max. intravenous tolerance for glucose in the dog is normally about 1.4 g. per kg. per hr. Blood-lactic acid rises

some time before death, and the alkaline reserve falls. The abnormal glycogen content of the liver is not the cause of death. The relations between liver-glycogen and N, and the liver and body wts. are studied. R. N. C.

Effect of camphor on the adrenaline reaction. I. Blood pressure. J. SZELÖCZEY. II. Dilatation of pupil and increase of blood pressure. J. SZELÖCZEY. III. Permeability and adsorption. J. SZELÖCZEY and B. KOLONITS (Magyar orvosi Arch., 1935, 36, 37—50, 51—55, 56—62; Chem. Zentr., 1935, ii, 241). G. H. F.

Spectrographic and biological study of phloridzin derivatives. I. Phloridzin hepta-acetate. A. LAMBRECHTS (Bull. Soc. Chim. biol., 1936, 18, 237—238).—Phloridzin hepta-acetate (I) shows an absorption band with a max. at 275 m $\mu$  and an extinction coeff. of 675. Injection of a solution of 10 mg. of (I) in EtOH produces a glycosuria of 17%, but this may be due to the hydrolysis of (I) by the blood. A. L.

Nutrition of the euglenia, *Astasia chattoni*. A. LWOFF and H. DUSI (Compt. rend., 1936, 202, 248—250).—Addition of fatty acid to the media considerably increases the reproduction. H. G. R.

Point of attack of acetylcholine in the heart. Does nicotine inhibit the cardiac action of acetylcholine? F. PLATTNER (Pflüger's Archiv, 1935, 236, 226—229). R. N. C.

Acetylcholine and the normal striped muscle of mammals. A. SIMONART and E. F. SIMONART (Arch. int. Pharmacodyn., 1935, 49, 302—328; Chem. Zentr., 1935, i, 3003). G. H. F.

Influence of thyroparathyroidectomy and of bile acids on bile secretion. S. TUZIOKA (J. Biochem. Japan, 1935, 22, 367—374).—The vol. of bile and the total bile acids of dogs (with biliary fistulæ) are diminished and the bile- $p_H$  is increased. Administration of Na taurocholate produces a return to normal vals. F. O. H.

Influence of bile acids on calcium metabolism. XII. Tetany and blood-calcium in thyroparathyroidectomised dogs. T. HOSHIZIMA (J. Biochem. Japan, 1935, 22, 375—383). F. O. H.

Influence of changes induced by cholesterol on the calcification *in vitro* of rabbit aorta. K. A. O. LAW and R. ROBISON (Biochem. J., 1936, 30, 69—75).—The development of typical cholesterol (I) arteriosclerosis by feeding rabbits on a diet rich in (I) is not associated with any increased proneness to calcification of the aorta *in vitro*, nor did the deposits so obtained specially favour those portions of the vessel in which the (I) lesions occurred. P. W. C.

Cholesterol as a growth factor for flagellates. R. CAILLEAU (Compt. rend. Soc. Biol., 1936, 121, 424—425). R. N. C.

Action of muscle-adenylic acid and related substances on the blood-supply of the skeletal muscle. W. SCHOEDEL (Pflüger's Archiv, 1935, 236, 93—101).—Adenylic acid (I) from muscle increases the blood-supply to skeletal muscle by 100—

170%, as do acetylcholine, adenosine, and adenosine triphosphate. The effect of yeast-(I) is < than that of muscle-(I). Inosic acid (except in large quantities), adenine, hypoxanthine, and carnine are without effect. The NH<sub>2</sub>-compounds and carbohydrate of muscle-(I) are responsible for the action. R. N. C.

Influence of administration of tonsil extracts on sugar excretion in rabbits. C. TATEISHI (J. Biochem. Japan, 1935, 22, 251—261).—The sugar excretion threshold is lowered by administration of small, and increased by large, amounts of extracts of pig's tonsil; the diminished level returns to normal on administration of cholic acid. F. O. H.

Action of the oxidase of *Cynara scolimus* in decreasing the blood-sugar. A. RISI (Rass. ter. Pat. clin., 1933, 5, 297—298; Bied Zentr., 1935, 6, A, 7).—Injection of the artichoke oxidase modifies the carbohydrate metabolism and induces a marked hypoglycemia in rabbits. A. G. P.

Effect of yeast and yeast extracts on intestinal motion. H. WASTL (Biochem. Z., 1936, 284, 24—39). W. McC.

Ether anaesthesia. Changes in serum-potassium during and following anaesthesia. B. H. ROBBINS and H. A. PRATT (J. Pharm. Exp. Ther., 1936, 56, 205—208).—The normal serum-K is for dogs 20 mg. and for guinea-pigs 34 mg. per 100 c.c. During Et<sub>2</sub>O anaesthesia, serum-K falls in both animals, and returns to normal within 5 hr. W. O. K.

Chemical constitution and local anaesthetic action of alkamine esters of *p*-alkoxybenzoic acids.—See this vol., 468.

Adrenaline secretion and blood-sugar content in dogs anaesthetised with avertin. H. SATO, Y. SATOW, and T. DEGUCHI (Tohoku J. Exp. Med., 1934, 24, 485—494).—Anaesthesia did not affect adrenaline output but slightly decreased the blood-sugar. CH. ABS. (p)

Muscle contractions without production of lactic acid. E. MARTINI (Arch. ital. Biol., 1935, 88, 82—90; Chem. Zentr., 1935, ii, 248). G. H. F.

Emetine sulphocamphorate. I. IMAZ and M. F. PASTOR (Rev. Assoc. med. Argentina, 1935, 49, 99—104).—Effects of the sulphocamphorate are similar to those of the hydrochloride, but its toxicity is lower. CH. ABS. (p)

Effect of ergotamine on glycosuria and hyperglycemia produced by stimulation of the superior cervical sympathetic ganglion. D. A. CLEVELAND (Amer. J. Physiol., 1935, 113, 592—594).—Ergotamine inhibits the above effects. R. N. C.

Heart activity and vegetative poisons. I. Effect of intravenous injections of atropine on the heart action. G. W. PARADE and J. G. JÄGER. II. Effect of intravenous injections of adrenaline and pilocarpine on the heart action. G. W. PARADE and H. R. FOERSTER (Klin. Woch., 1934, 13, 1684—1686, 1709—1711). R. N. C.

Respiratory effects of morphine, codeine and related substances. V. Effect of  $\alpha$ -,  $\beta$ -, and

$\gamma$ -isomorphines and their dihydro-derivatives on the respiration of the rabbit. C. I. WRIGHT and F. A. BARBOUR (J. Pharm. Exp. Ther., 1936, 56, 39—49).—The min. subcutaneous doses of  $\alpha$ -,  $\beta$ -, and  $\gamma$ -isomorphine and dihydro- $\alpha$ -,  $\beta$ -, and  $\gamma$ -isomorphine required to depress the respiratory mechanism of the rabbit are 0.55, 8.0, 8.0, 0.4, 0.55, and 5.3 mg. per kg., respectively. A. L.

Effect of morphine on the human ureter. N. F. OCKERBLAD, H. E. CARLSON, and J. F. SIMON (J. Urol., 1935, 33, 356—362). CH. ABS. (p)

Effect of quinine on tissue respiration: relation between quinine and various hormones in this respect. I. Insulin or adrenaline. II. Genital glands. K. MIZUTANI (Folia Endocrinol. Japon., 1933, 8, 97—98, 98—99).—I. Injection of quinine (I) lowered the  $O_2$  consumption of liver, kidney, thyroid, spleen, and heart muscle to a small extent, and that of skeletal muscle markedly. Administration of insulin increased this effect on liver and thyroid and decreased it in all other organs. Adrenaline in all cases retarded the action of (I).

II. Feeding of dried testicle to male rats decreased these effects of (I) in all organs, especially thyroid. Interstitial tissue of the ovary had a similar, and corpus luteum a reverse, action in the case of female rats.

CH. ABS. (p)

Site and mode of action [of therapeutic substances] and intermediary metabolism. H. FREUND (Arch. exp. Path. Pharm., 1936, 180, 416—436).—Intermediary metabolism is dependent on the condition of the organ. The site and mode of action of a therapeutic substance are changed by changes in tissue metabolism. The relations between variation in metabolic processes and the action of drugs etc. are exemplified.

F. O. H.

Relation between the toxicities and the b.p. of related substances. J. FERGUSON (Nature, 1936, 137, 361—362).—An exact linear relationship exists between the b.p./1 atm. of a series of related compounds and the log of the molar lethal doses to insects for the most diverse cases. Data for the action of chlorinated ethylenes on *Sitophilus granarius* are given. In a homologous series or a series of substituted derivatives the effect of the substituent is probably purely physical, increasing the availability of the toxic grouping of the parent substance.

L. S. T.

Relation between toxicity, resistance, and time of survival. L. REINER (J. Gen. Physiol., 1936, 19, 419—422; cf. A., 1934, 323, 551).—Theoretical. A more general form of the equations is given, consistent with a limiting toxicity with increasing concn. of drug.

F. A. A.

Treatment of military gas poisoning. E. GILLERT (Therap. d. Gegenwart, 1934, 75, 529—537; Chem. Zentr., 1935, i, 3814).

H. N. R.

Chronic carbon monoxide poisoning. H. BURESCH (Z. Hyg., 1935, 117, 153—160).

R. N. C.

Action of alcohol and some other poisons on heart inhibition in the frog. C. G. SANTESSON (Skand. Arch. Physiol., 1934, 69, 255—292).

R. N. C.

Relative toxicity of acetone, methyl alcohol, and their mixtures. I. R. M. SKLIANSKAYA, F. E. URIEVA, and L. M. MASHBITZ. II. Action on white mice. L. M. MASHBITZ, R. M. SKLIANSKAYA, and F. E. URIEVA (J. Ind. Hyg., 1936, 18, 106—116, 117—122).—I.  $COMe_2$  depresses the activity of the isolated frog's heart more powerfully than MeOH, but recovery occurs more readily after  $COMe_2$ . Mixtures of  $COMe_2$  and MeOH show the predominant effect of  $COMe_2$ .

II. Measured by commencement of narcosis, the toxicity of  $COMe_2$  is  $>$  that of MeOH, but according to mortality, MeOH is more toxic than  $COMe_2$  or their mixtures. With mixtures of 40, 50, and 60% of  $COMe_2$ , the toxicity is  $<$  that of the separate compounds.

J. N. A.

Toxicity and potential dangers of ethylene glycol. F. H. WILEY, W. C. HUEPER, and W. F. VON OETTINGEN (J. Ind. Hyg., 1936, 18, 123—126).—A concn. of 300 mg. of  $(CH_2OH)_2$  per 1000 litres of air has no toxic effects on mice or rats, and probably none on man, even with continued exposure of 8 hr. per day for  $3\frac{1}{2}$  months.

J. N. A.

Simultaneous poisoning of frog's muscle with veratrine and iodoacetic acid. J. MÄRTENSSON (Skand. Arch. Physiol., 1935, 71, 229—237; Chem. Zentr., 1935, i, 3004).

G. H. F.

Antiseptic properties of wine. E. CERIOTTO (Semana méd., 1935, 42, 529—532; Chem. Zentr., 1935, ii, 290).—The antiseptic activity of wine *in vivo*, not *in vitro*, is ascribed to the presence of colloidal metals.

H. N. R.

Toxicity of potassium perrhenate. L. C. HURD, J. K. COLEHOOR, and P. P. COHEN (Proc. Soc. Exp. Biol. Med., 1933, 30, 926—928).—In contradistinction to  $KMnO_4$ ,  $KReO_4$  had low toxicity when injected intraperitoneally into rats or mice. In rabbits Re was conc. mainly in the urine with some distribution in the organs, but not in the brain.

CH. ABS. (p)

Relative toxicity of thiocyanate ions. P. BRUN (Compt. rend. Soc. Biol., 1936, 121, 543—546).—CNS' is equally toxic to germinating seeds, infusoria, and fish, but the toxicity is very feeble compared with that of  $CN'$ .

R. N. C.

Muscle metabolism in arsenic-treated rabbits. W. NONNENBRUCH, Z. STARY, A. BAREUTHER, and H. THELEN (Arch. exp. Path. Pharm., 1936, 180, 437—439).—The hexosemono- and adenylypyro-phosphoric acid contents of the muscle are diminished, due to a decrease in phosphorylation processes (cf. A., 1934, 1250).

F. O. H.

Halide distribution in body fluids in chronic bromide intoxication. M. F. MASON (J. Biol. Chem. 1936, 113, 61—74).—The distribution of  $Br'$  and  $Cl'$  in simultaneously taken samples of blood, spinal fluid, urine, gastric juice, and saliva from dogs and patients with chronic bromism has been determined. The distribution ratio for  $Br'$  between cells and serum is slightly  $>$  for  $Cl'$ , whilst that between serum and spinal fluid is much  $>$  for  $Cl'$ . The replacement of  $Cl'$  by  $Br'$  in urine is  $<$  in serum. In gastric juice the replacement is sometimes  $>$  and

sometimes < in serum. In dog's parotid saliva the replacement is approx. the same as in serum, whilst in human mixed saliva it is much greater.

J. N. A.

**Augmentation of the toxicity of fluorosis in the chick by feeding desiccated thyroid.** P. H. PHILLIPS, H. ENGLISH, and E. B. HART (J. Nutrition, 1935, 10, 399—407).

A. G. P.

**Experimental salt poisoning in ducks.** J. P. TORREY and R. GRAHAM (Cornell Vegetarian, 1935, 25, 50—53).

CH. ABS. (p)

**Pharmacology of the nitrite effect of bismuth subnitrate.** E. J. STIEGLITZ and A. E. PALMER (J. Pharm. Exp. Ther., 1936, 56, 216—222).— $\text{Bi}(\text{OH})_2\text{NO}_3$  or  $\text{NaNO}_3$ , added to cultures of *B. coli*, is partly reduced to nitrite (I). After oral administration of  $\text{Bi}(\text{OH})_2\text{NO}_3$  in therapeutic doses, the blood-(I) (normal,  $0.5\text{--}1.5 \times 10^{-6}$  g. per 100 c.c.) usually rises significantly, whilst the arterial blood pressure falls.

W. O. K.

**Lead in drinking-water.** F. WEYRAUCH and H. MÜLLER (Z. Hyg., 1935, 117, 196—201).—Traces of Pb in the drinking-water of German towns are probably responsible for the Pb present in human bones.

R. N. C.

**Treatment of plumbism.** I. GRAY (J. Amer. Med. Assoc., 1935, 104, 200—205).—A low-Ca, high-P (ratio 1:3—4) diet together with administration of  $\text{NH}_4\text{Cl}$  and  $\text{H}_3\text{PO}_4$  increased the elimination of Pb.

CH. ABS. (p)

**Biochemical behaviour of lead in the body.** J. C. AUB (J. Amer. Med. Assoc., 1935, 104, 87—90).—A review.

CH. ABS. (p)

**Acute poisoning from mercuric chloride.** T. SOLLMANN and N. E. SCHREIBER (Arch. Int. Med., 1936, 57, 46—62).—The average [Hg] in the organs of fatal cases of  $\text{HgCl}_2$  poisoning was: kidneys 3.8, liver 2.05, spleen 0.55, intestines 0.43, heart, skeletal muscle, and lungs 0.20—0.30, brain 0.14, blood 0.015—0.12 mg. per 100 g.

H. G. R.

**Selenium in proteins from toxic foodstuffs.** IV. Effect of feeding toxic proteins or toxic protein hydrolysates with and without removal of selenium. K. W. FRANKE and E. P. PAINTER (J. Nutrition, 1935, 10, 599—611).—Hydrolysates ( $\text{H}_2\text{SO}_4$ ) of toxic proteins retain the toxic factor, but become innocuous after pptn. of Se compounds by  $\text{HgCl}_2$ .

A. G. P.

**Toxicant occurring naturally in certain samples of plant foodstuffs.** XI. Effect of feeding toxic and control foodstuffs alternately. K. W. FRANKE (J. Nutrition, 1935, 10, 233; cf. this vol., 105).—Further data relating to the effects of "toxic" maize are given.

A. G. P.

**Acridine compounds.**—See this vol., 484.

**Succession of enzymic processes in muscular tissue.** J. K. PARNAS (Bull. Soc. Chim. biol., 1936, 18, 53—85).—A lecture.

**Mode of combination of an enzyme with an adsorbent and with a substrate.** K. G. STERN (Science, 1936, 83, 190—191).

L. S. T.

**Rôle of the concentration (A) of the co-enzyme, (B) of the substrate, in the rate of fermentation reactions.** L. AMBARD and S. TRAUTMANN (Compt. rend. Soc. Biol., 1936, 121, 470—472, 472—473).—(A) The variations in the fixation of the co-enzyme with univalent anionic concn. at const.  $p_{\text{H}}$  and in the concn. of the co-enzyme with  $[\text{H}^+]$  at const. univalent anionic concn. are confirmed.

(B) The rate of formation of the substrate-enzyme-co-enzyme complex in the inversion of sucrose (I) by invertase is inversely  $\propto$  the concn. of (I), but the rate of hydrolysis of the complex is independent of (I) concn.

R. N. C.

**How can water intervene in the calculation of enzymic reactions?** L. THIVOLLE (Compt. rend. Soc. Biol., 1936, 121, 476—477).—Theoretical.

R. N. C.

**Effect of ultra-violet light on enzymic reactions.** II. Pepsin. S. BANERJEE and H. K. SEN (J. Indian Chem. Soc., 1935, 12, 740—746; cf. A., 1935, 1415).—Ultra-violet light does not affect the action of pepsin on caseinogen at  $p_{\text{H}}$  1.8, when the peptic val. is a max. The influence of various org. and inorg. additions on the peptic val. is also investigated and the mechanism of the action is discussed.

R. S.

**Similarity between the mechanism of the rennin and pectase (pectin-methoxylase) reactions.** A. C. DAHLBERG and Z. I. KERTESZ (Science, 1936, 83, 56).

L. S. T.

**Lysozyme.** K. MEYER, R. THOMPSON, J. W. PALMER, and D. KHORAZO (J. Biol. Chem., 1936, 113, 303—309).—The method of prep. has been modified to include separation as the flavianate. Lysozyme is a basic polypeptide (15.3% N) active only in the reduced state.

H. G. R.

**Activation of villikin.** E. VON KOKAS and G. von LUDÁNY (Pflüger's Archiv, 1935, 236, 166—174).—Villikin is activated only by the HCl of the gastric juice; it is also activated by other acids, the activating powers of which vary, but not by NaOH, NaCl,  $\text{H}_2\text{O}$ , EtOH,  $\text{COMe}_2$ , urea, glycerol, or sucrose. When activated, it is sol. in  $\text{H}_2\text{O}$ , neutral salts, dil. alkali, and EtOH. It exists in the intestinal mucosa as an inactive heat-resistant precursor (provillikin).

R. N. C.

**Anhydrase activity in invertebrates.** M. FLORKIN (Arch. Int. Physiol., 1935, 40, 283—290; Chem. Zentr., 1935, i, 2997).—The occurrence of carbonic anhydrase of Meldrum and Roughton (A., 1933, 844) in many invertebrates is proved.

G. H. F.

**Influence of different diets on enzymes of the organism.** I. The problem. II. Starvation and blood enzymes. III. Insufficient consumption of proteins and the blood-enzymes. B. GOLDSTEIN (Ukrain. Biochem. J., 1934, 7, No. 1, 79—94, 95—107, 109—123).—I. A discussion.

II. Starvation caused no typical changes in blood-catalase (I), a slight initial increase followed by a decrease in -amylase (II), and a progressive and marked decline in -lipase (III). The (III) content

and the decomp. of albumin in the organism were unrelated.

III. Insufficient consumption of protein (such as to cause death in 30—40 days) effected no change in (I) or (II) but an increase in (III) which is paralleled by the decrease in wt. of the animal. Elimination of  $\text{NH}_2$ -acids (tryptophan, cystine, tyrosine) is of no importance in the formation of (III), which may serve as an index of protein sufficiency. CH. ABS. (p)

**Components of dehydrogenase systems. IX.** Cozymase and "codehydrogenase II." H. VON EULER and E. ADLER. **X.** Lactic acid dehydrogenase and malic acid dehydrogenase from heart muscle. E. ADLER and M. MICHAELIS. **XI.** Glucose dehydrogenase from liver. N. DAS (Z. physiol. Chem., 1936, 238, 233—260, 261—268, 269—274; cf. A., 1935, 1276).—IX. In addition to cozymase (I) yeast contains codehydrogenase II (II), (probably identical with the co-enzyme of red blood-cells), which is separated from (I) by chromatographic adsorption on  $\text{Al}_2\text{O}_3$  and is a necessary component of the dehydrogenase system of Robison's ester; (I) is a necessary component of the alcohol dehydrogenase system of yeast, (II) being inactive in the second system and (I) in the first. Both (I) and (II) act as H carriers.

X. The dehydrogenation of lactic acid (III) by the enzyme of heart muscle is activated by flavin enzyme (a necessary constituent), which is partly separated from (III) dehydrogenase by chromatographic adsorption on  $\text{Al}_2\text{O}_3$ . In the (III) and malic acid dehydrogenase systems (I) is the activating co-enzyme, (II) from yeast and red blood-cells having no effect.

XI. Both (I) and (II) activate the glucose dehydrogenase system of liver and (II) occurs in liver.

W. McC.

**Inhibiting action of hydrogen cyanide on biological oxidations.** E. J. BIGWOOD, J. THOMAS, and H. HERBO (Bull. Soc. Chim. biol., 1936, 18, 176—181).—Determinations of the amount of uric acid formed in the aerobic and anaerobic oxidation of hypoxanthine by xanthine-dehydrogenase from milk indicate that the aerobic oxidation is inhibited by HCN. This suggests that indophenol-oxidase is involved.

A. L.

**Histochemical investigation of oxidases by the indophenol-blue reaction. Application to lipins.** L. LISON (Bull. Soc. Chim. biol., 1936, 18, 185—189).—The indophenol-blue obtained on treating certain fatty substances with the Nadi reagent is produced by the oxidation of the reagent by the fatty substances and not by the preferential dissolution of the autoxidised reagent or by the presence of an oxidase. This view is supported by the fact that pure unsaturated lipins such as oleic acid, when kept exposed to the air, bring about the oxidation of benzidine by peroxidase.

A. L.

**Action of carbon monoxide on the indophenol-oxidase in milk.** E. J. BIGWOOD, J. THOMAS, and H. HERBO (Bull. Soc. chim. biol., 1936, 18, 182—184).—CO in the dark is without effect on the aerobic oxidation of hypoxanthine or the Nadi reagent by the xanthine-dehydrogenase from milk. The system

is therefore similar in behaviour to that of succino-dehydrogenase from muscle.

A. L.

**Action of neutral salts of the Hofmeister series on diastatic enzymes.** W. HAARMANN and O. FOLSCHKE (Biochem. Z., 1936, 283, 312—321).—In isotonic and unbuffered solutions, all neutral salts inhibit the conversion of starch into sugar by diastase (I). Animal (I) is particularly strongly inhibited by  $\text{OAc}'$ ,  $\text{PO}_4'''$ , and  $\text{I}'$  whilst  $\text{SO}_4''$ ,  $\text{Cl}'$ , and tartrate are only feebly inhibitory. Malt-(I) is strongly inhibited by all the salts, least by  $\text{I}'$ . In alkaline solution the activity of animal (I) is increased by neutral salts, particularly by  $\text{Cl}'$  and  $\text{SO}_4''$ , and that of malt-(I) is increased by  $\text{SO}_4''$ ,  $\text{OAc}'$ , and tartrate but not by  $\text{Cl}'$  and  $\text{I}'$ . The increase in alkaline solution does not occur at high concns. of the salts. In acid solution practically no activation occurs.

P. W. C.

**Influence of the chlorides of alkalis and of alkaline earths on the saccharification of starch by diastatic enzymes.** W. HAARMANN and K. BAERTSCHER (Biochem. Z., 1936, 283, 301—311).—In neutral and acid solution  $\text{Cl}'$  in low concn. accelerates by 20% and in higher concns. inhibits the activity of malt-diastase (I);  $\text{NaCl}$  and  $\text{MgCl}_2$  inhibit by 70% and other chlorides (except  $\text{LiCl}$ ) by 50%. Animal (I) under the same conditions is not or only slightly affected. In alkaline solution, the activity of animal (I) was considerably increased whereas that of plant (I) was inhibited. With increasing concn. the action of  $\text{Cl}'$  varies in a characteristic way for each cation, the accelerating action with animal (I) being gradually decreased and the inhibition of plant (I) increased.

P. W. C.

**Sisto- and eleuto-amylase.** R. DEPLANQUE (Z. Spiritusind., 1936, 59, 60, 62).—A lecture.

**Influence of heavy water on activity and stability of pancreatic amylase.** M. L. CALDWELL, S. E. DOEBBELING, and S. H. MANIAN (J. Amer. Chem. Soc., 1936, 58, 84—87).—The hydrolysis of starch by pancreatic amylase (I) is not influenced to any marked extent by  $\text{D}_2\text{O}$  (concn. up to 100%), provided deterioration of (I) is avoided. Inactivation of (I) occurs more rapidly and to a greater extent in  $\text{D}_2\text{O}$  than in  $\text{H}_2\text{O}$  at  $25^\circ$ .

H. B.

**Taka-amylase. VII. Purification by adsorption. VIII—X. Selectivity of different adsorption materials.** T. KITANO (J. Soc. Chem. Ind. Japan, 1936, 39, 22—24B, 24B, 25—26B, 26B; cf. A., 1935, 1535).—Separation of taka-amylase (I) from maltase (II) by adsorption is attempted. Adsorption is rapid, and greater at lower temp. Graphite has no adsorptive action. The relative adsorptive power, for (I) and (II), of various charcoals and earths, of kaolin, and of  $\text{Cu}(\text{OH})_2$  and  $\text{Fe}(\text{OH})_3$  is examined. By none of these is (I) obtained free from (II). The optimum action on starch and on maltose is at the same  $p_{\text{H}}$  (4.6). (I) may be a form of Ohlsson's saccharogenamylase ( $\beta$ -amylase).

E. W. W.

**Action of some oxidisers on amylolysis and alcoholic fermentation in flour paste.** R. GUILLEMET and C. SCHELL (Compt. rend. Soc. Biol., 1936,

121, 463—464).—Amylolysis in paste is increased by  $K_2S_2O_8 \propto$  the concn., and by  $KBrO_3$  and  $K_3BO_3$ , which show max. effect in min. concn. R. N. C.

**Determination of amylolytic activity of pancreatin.** A. DE CLERCQ (J. Pharm. Belg., 1935, 17, 95—98; Chem. Zentr., 1935, i, 2997).—The methods of the Belgian, American, French, and Spanish pharmacopœias are compared. The reaction on starch for  $< 1$  hr. at  $37^\circ$  is recommended. G. H. F.

**Hydrogen sulphide as a factor in the determination of free and bound amylase in ungerminated cereals.** T. CHRZASZCZ and J. JANICKI (Biochem. J., 1936, 30, 342—344; cf. this vol., 245).—More bound amylase is liberated in aq. extracts of barley, rye, and wheat by added  $H_2S$  than by added papain. The amount liberated when shaking is intermittent is  $>$  when it is continuous.

W. McC.

**Enzymic fission of glucosides in heavy water.** F. SALZER and K. F. BONHOEFFER (Z. physikal. Chem., 1936, 175, 304—321).—The results of investigations of the fission of  $\beta$ -glucosides by emulsin are examined in relation to the Michaelis-Menten theory of the velocity of enzymic reactions (A., 1913, i, 540). If the enzyme is almost saturated with substrate the rate of fission in  $D_2O$  solution is  $<$  in  $H_2O$ , showing that the hydrolytic decomp. of the enzyme-substrate complex is slower. If only a small part of the enzyme is combined with substrate fission is more rapid in  $D_2O$  than in  $H_2O$ , showing that the affinity of the enzyme for the substrate in  $D_2O$  is  $>$  in  $H_2O$ . Similar considerations are applicable to hydrolyses catalysed by  $H^+$ . The hydrolysis of salicin is more rapid in  $D_2O$  than in  $H_2O$ , indicating that the first step of the reaction is the formation of a complex of  $H^+$  and substrate at a speed which is high compared with that of the subsequent decomp. into  $H^+$  and products of hydrolysis. If, however, the first step is the slower, the rate of reaction may be higher in  $H_2O$  than in  $D_2O$ . The Michaelis consts. of *p*-cresol-glucoside and *n*-butylglucoside are 0.14 and 0.22, respectively, at  $30^\circ$ .

R. C.

**Action of emulsin. III. Sources of error in the polarimetric examination of enzymic hydrolysis of  $\beta$ -glucosides.** S. VEIBEL and F. ERIKSEN (Biochem. J., 1936, 30, 163—167).—Before the polarimetric determination the enzymic reaction is stopped by adding  $K_2CO_3$ , which raises the  $p_H$  of the solution from 4.4 to 10.5—10.6. The difference in rotation at these two  $p_H$  vals. is about 3—4%. Glucose solutions are unstable at  $p_H$  10.6; 0.1M solutions decrease in  $\alpha$  by  $0.0033^\circ$  per hr. Salicin is used as a standard glucoside; a concn. of 3.972% should be used (cf. Helferich, A., 1931, 873). PhMe should not be used as a bactericide as it accelerates the rate of enzymic hydrolysis by 25—35%.

E. A. H. R.

**Kinetics of ester hydrolysis by enzymes. VI. Relative specificity of esterases.** E. BAMANN and E. RENDLEN (Z. physiol. Chem., 1936, 238, 133—144; cf. A., 1934, 218).—The varying affinity of pig's liver esterase for  $Me_1$  and  $Me_2$  esters and  $Me$  ester amides of dicarboxylic acids (malonic to adipic) and the effects of altering  $[H^+]$  and substrate concn. con-

firm the view that the enzyme-binding power of the ester group of the substrate is controlled by the electrochemical nature of the adjacent groups. The predominating effect of the acid group in preventing production of the enzyme additive compound can be counteracted or restricted by increasing the distance between ester and  $CO_2H$  group, by esterifying  $CO_2H$  or converting it into  $CO-NH_2$ , and by reducing the degree of dissociation of  $CO_2H$ .

W. McC.

**Determination of activity of lipase and esterase.** H. PÉNAU and J. GUILBERT (J. Pharm. Chim., 1936, [viii], 23, 57—77).—The activity of the lipase (I) and esterase (II) of blood-serum is determined by measuring the extent of hydrolysis (at  $40^\circ$  with shaking) in 2 hr. of tributyrin [for (I)] and  $Pr^aCO_2Et$  [for (II)]. After the digestion  $NaPO_3$  and 0.1N- $H_2SO_4$  are added ( $p_H$  3.5), the mixture is centrifuged, and the liquor and washings are extracted 3 times with  $Et_2O$ . After addition of  $EtOH$  and  $H_2O$  the extract is titrated with 0.1N-NaOH (bromothymol-blue). In the dog there is little variation in the activities. Differences in the activities amongst animal species may be due to the presence of activators and inhibitors.

W. McC.

**Enzymic hydrolysis of tributyrin by pancreatic lipase.** A. I. VIRTANEN and E. LINDEBERG (Suomen Kem., 1936, 9, B, 2).—The hydrolysis proceeds in three stages: tributyrin  $\rightarrow$   $\alpha$ -dibutyryl  $\rightarrow$  monobutyryl  $\rightarrow$  glycerol. Each stage has a different reaction velocity.

J. N. A.

**Cathepsin and arginase in a melanoma of the horse.** A. PURR (Z. Krebsforsch., 1935, 41, 483—487; Chem. Zentr., 1935, i, 2998).—Melanomas of horse differ in their cathepsin (I) and arginase (II) contents from other malignant tumours; compared with rat sarcoma, the (I) content is much higher and the (II) content very low.

G. H. F.

**Determination of amino-acids in crystalline pepsin.** H. O. CALVERY, R. M. HERRIOTT and J. H. NORTHROP (J. Biol. Chem., 1936, 113, 11—14).—Cryst. pepsin has been analysed for total N,  $NH_2-N$  (before and after acid hydrolysis), humin-N, amide-N, tyrosine, tryptophan, cystine, arginine, histidine, lysine, aspartic and glutamic acid. The low basic N val. and the very high  $NH_2-N$  val. after acid hydrolysis are noteworthy. Coagulation by heat at  $p_H$  4 appears to cause partial destruction of the pepsin mol. and marked differences are shown by analyses of the coagulated and non-coagulable material.

H. W.

**Determination of peptic activity.** H. ESCHENBRENNER (Pharm. Ztg., 1936, 81, 229—231).—A direct measure of peptic activity cannot be obtained by a titration method or by the change in  $\eta$  on digestion. Preliminary observations are reported dealing with the possibility of using the ratio of  $\eta$  to titration vals. as a measure of the activity.

E. A. H. R.

**Fission of arginine during proteolytic hydrolysis.** S. KAMIYA (J. Biochem. Japan, 1935, 22, 263—277).—Liberation of arginine (I) during proteolytic hydrolysis of edestin, caseinogen, and gelatin was followed by treating aliquots of the hydrolysate at intervals with protease-free arginase preps. (from

pig's liver) and then determining (I) by the urease method; increase in  $\cdot\text{CO}_2\text{H}$  was followed by titration with 0.1N-KOH. Pepsin (II) (7—8 days) does not liberate (I) whilst  $\cdot\text{CO}_2\text{H}$  is increased by 8.5—27% of the total  $\cdot\text{CO}_2\text{H}$  liberation by (II)—trypsin (III)—erepsin (IV). Subsequent digestion by (III) (7—12 days) liberates 26.9—43.5% of the total (I) and increases  $\cdot\text{CO}_2\text{H}$  by 43.3—76.6%. Final digestion by (IV) (22 days) liberates 63.4—80.4% of (I). Liberation of (I) by (II)–(IV) hydrolysis is > that by (II)–(III)–(IV) hydrolysis.

F. O. H.

**Action of trypsin on substituted protein.** A. KIESEL and O. ROGANOVA (Z. physiol. Chem., 1936, 238, 149—159).—Substitution products of edestin (I) are less readily attacked by trypsin than is (I) itself, the effect being moderate or slight in the case of ethylated, sulphonated, and deaminated (I) and very great with benzoyl- (II), benzoylmethyl-, and benzoyl-deamino-destin (III). When the substituents are removed from (II) and (III) the product is nearly as readily attacked as is (I) itself. Probably the  $\text{NH}_2$  and OH groups (but not  $\text{CO}_2\text{H}$ ) play an important part in the process.

W. McC.

**Digestive enzymes in marine invertebrates.** I. **Proteolytic enzymes in *Polypus vulgaris* (Lamarck).** E. SAWANO (Sci. Rep. Tokyo Bunrika Daigaku, 1935, 2, B, 101—126).—The acidity of the digestive tract of *P. vulgaris* increases from the pharynx ( $p_{\text{H}}$  6.8) to the intestine ( $p_{\text{H}}$  5.5). The distribution of proteinase, amino- and carboxy-polypeptidase, and dipeptidase in the digestive tract, anterior and posterior salivary glands, liver, and pancreas is recorded. The  $p_{\text{H}}$  optima of these four enzymes appear to be unaffected by the nature of the tissues in which they occur. A cathepsin-like proteinase occurs in extracts of liver and pancreas.

E. A. H. R.

**Urinary phosphatase. II. Excretion by man.** H. WOLBERGS (Z. physiol. Chem., 1936, 238, 23—30; cf. Kutscher, A., 1935, 1279).—Details are given of work already reported (A., 1935, 1268). A difference (due to prostatic secretion) exists between the urines of the two sexes. Injection of insulin has the reverse action to, and inhibits, that of glucose administration.

F. O. H.

**Urinary phosphatase. III.** W. KUTSCHER and A. WÖRNER (Z. physiol. Chem., 1936, 238, 275—279; cf. Wolbergs, this vol., 111).—When urine is dialysed through parchment the activity of the phosphatase is increased. Subsequent electro dialysis, repeated with the solution obtained by dissolving in  $\text{H}_2\text{O}$  the active material which separates after 12—24 hr. on the first occasion, results in a high degree of purification accompanied by only slight loss of activity.

W. McC.

**Specificity of phosphatases.** W. SCHUCHARDT (Biochem. Z., 1936, 283, 433—434).—A sample of yeast when tested with dil. AcOH did not attack  $\alpha$ - and  $\beta$ -glycerophosphate between  $p_{\text{H}}$  6 and 9 and when treated with dil. aq.  $\text{NH}_3$  was inactive between  $p_{\text{H}}$  3.3 and 5.

P. W. C.

**Phosphatase action of emulsin.** H. BREDERECK and H. BEUCHELT (Naturwiss., 1936, 24, 107—108).—Active emulsin preps. from almonds bring about a

rapid cleavage of  $\text{H}_2\text{PO}_4$  from mononucleotides and yeast-nucleic acid. The glycosidic linking in purine nucleotides is not attacked.  $\text{H}_3\text{PO}_4$  is also liberated, although less rapidly, from glycerophosphoric acid.

E. A. H. R.

**Rôle of water in the activation of renal phosphatase.** L. THIVOLLE (Compt. rend. Soc. Biol., 1936, 121, 474—476).—The rate of fermentation by renal phosphatase (I) is increased by dilution, there being an optimum dilution depending on the amount of (I) present.

R. N. C.

**Chemical difference between protein-linked and free nucleic acid.** G. SCHMIDT (Science, 1936, 83, 15).—The observed difference in the rates of dephosphorylation of thymonucleic acid and thymonucleohistone by phosphatase is due to the linking of the nucleic acid component with the protein.

L. S. T.

**Anaërobic decomposition of hexosephosphoric acids by animal tissues. III. Hydrolysis by phosphatase.** T. TAKAHASHI (J. Biochem. Japan, 1935, 22, 303—321).—Production of hexose monophosphate and free sugar from hexose diphosphate by autolysed tissue is not invariably accompanied by formation of  $\text{AcCHO}$ .

F. O. H.

**Phosphodiesterase and hydrolysis of lecithin.** H. UDAGAWA (J. Biochem. Japan, 1935, 22, 323—340).—Diphosphatase preps. (from taka-phosphatase) free from monophosphatase hydrolyse lecithin (optimum  $p_{\text{H}}$  4—5) to the corresponding glyceride and cholinephosphoric acid, the latter being further hydrolysed only by monophosphatase.

F. O. H.

**Animal lipins. X. Cerebrosidase. Its relation to the splitting of polydiaminophosphatide by polydiaminophosphatase.** S. J. THANNHAUSER and M. REICHEL (J. Biol. Chem., 1936, 113, 311—317).—Cerebrosidase is inactive, its activators, which depress polydiaminophosphatase activity, being  $\text{H}_2\text{S}$ , cysteine, reduced glutathione, and *l*-ascorbic acid.

H. G. R.

**Hexokinase.** O. MEYERHOF (Naturwiss., 1935, 23, 850—851).—If glucose and adenylyl pyrophosphate are incubated with hexokinase (I), adenylic acid and hexose monophosphate are formed. If this mixture is boiled and added to fresh muscle extract lactic acid is rapidly formed. (I) probably acts by causing phosphorylation of sugars.

E. A. H. R.

**Fermentative enzymes. V. Phosphorylation systems of alcoholic fermentation.** A. SCHÄFFNER and H. BERL (Z. physiol. Chem., 1936, 238, 111—123; cf. A., 1935, 1026; this vol., 246).—Phosphorylation of hexose by macerated yeast is induced equally by hexose diphosphate (I) and adenosine triphosphate (II). Purification of the enzyme system results in induction by (I) [or by dihydroxyacetonephosphoric acid (III)] but not by (II); hence "phosphatase" is not identical with the "heterophosphatase" of Euler and Adler (A., 1935, 1276) and thus at least two phosphorylating systems exist in yeast extracts. A third system, whereby the monoester is converted into the diester, is probably also present, the mechanism being one of oxidation to a phosphohexonic acid and subsequent fission to

$\text{AcCO}_2\text{H}$  (decarboxylated to  $\text{MeCHO}$ ) and triose-phosphoric acid [2 mols. of which give 1 mol. of (I)]. Pyrophosphatase and Warburg's intermediary enzyme are also concerned in phosphorylation processes. A consideration of the rôle of (III) and of phosphoglyceric acid (IV) and of inhibition by  $\text{CH}_2\text{I}\cdot\text{CO}_2\text{H}$  indicates that the reaction  $\text{glucose} + \text{phosphate} \rightarrow \text{hexose ester}$  is coupled with the oxidation-reduction process  $(\text{III}) + \text{MeCHO} \rightarrow (\text{IV}) + \text{EtOH}$ . Intra- and extra-cellular phosphorylation processes are compared.

F. O. H.

**Transformation of the pyrophosphate fraction in yeast cells.** M. M. LEVITOV (Biochem. Z., 1936, 284, 86—98).—Fresh yeast in aq. suspension loses very little of its pyrophosphate (I) content in 5 hr., but considerable loss of (I) and of orthophosphate (II) occurs when glucose (III) is added. No appreciable change in the (I) and (II) contents of fermenting (glucose) yeast occurs if fermentation is inhibited by  $\text{CH}_2\text{Br}\cdot\text{CO}_2\text{H}$  and respiration by KCN but when fermentation is inhibited with NaF the (I) and (II) contents decrease. Addition of (III) checks the degradation of (I) which occurs on autolysis. Phosphoglyceric acid acts more powerfully than does (III), thus causing the diminished (I) content to increase. The (I) compound of yeast seems to act as a phosphate carrier in the same way as does adenosinetriphosphoric acid in animal cells.

W. McC.

**Inverse Pasteur reaction.** W. A. BELITZER (Biochem. Z., 1936, 283, 339—342).—Working with yeast, the inverse Pasteur reaction is observed only when the respiration system is saturated with a suitable H donor.

P. W. C.

**Sporulation of yeast.** II. H. STANTIAL (Trans. Roy. Soc. Canada, 1935, [iii], 29, III, 175—188).—Formation of ascospores by *S. cerevisiae* is increased by grapefruit juice, the active constituent of which is a carbohydrate [of 12 investigated, 8 (especially mannose and maltose) were active]. Aq. NaOAc or KOAc in presence of sugar is effective. Data for the influence of temp. and  $p_{\text{H}}$  on sporulation are given.

F. O. H.

**Wildier's bios.** W. L. MILLER (Trans. Roy. Soc. Canada, 1935, [iii], 29, III, 163—165).—Amino-hydroxybutyric acid (I) (from crotonic, isocrotonic, and phenoxyethylmalonic acid), aspartic (II) + amino-isobutyric acids, (II) +  $\alpha$ -aminobutyric acid or  $d$ -glutamic acid + alanine cannot replace the (I) isolated from tomato juice as a source of bios IIA in the growth of yeasts. Of 32  $\text{NH}_2$ -acids only  $l$ -leucine (III) had a significant effect; (III), however, also enhances the action of bios IIA. Wildier's bios appears to contain four constituents, viz., a (I), inositol, (III), and bios IIB (which is purified by the use of  $\text{COMe}_2$  and Cu and Hg acetates). Bios V is necessary for the growth of *S. hanseniospora valbyensis*.

F. O. H.

**Influence of inositol and bios IIA and IIB on the reproduction of twelve yeasts. New constituent of bios.** L. N. FARRELL (Trans. Roy. Soc. Canada, 1935, [iii], 29, III, 167—173).—*S.* and *Zyg. mandshuricus* are indifferent to inositol whilst *Zyg. mellis* is only slightly influenced. *S. hanseniospora valbyensis* and *S. galactosus* require an additional

factor (I). The remainder resemble Wildier's yeast. (I) (bios V; cf. preceding abstract) occurs in tomato and lemon juice and is not identical with ascorbic acid.

F. O. H.

**Balance of alcoholic fermentation by yeasts.** R. GUILLEMET (Compt. rend. Soc. Biol., 1936, 121, 465—467).—Anaërobic fermentation of sucrose, glucose, and fructose in aq. solution by yeasts reaches equilibrium in a few hr., with production of equimol. quantities of EtOH and  $\text{CO}_2$ . Maltose exhibits anomalies; some disappears without production of EtOH and  $\text{CO}_2$ , being probably broken down to intermediate products. Production of  $\text{CO}_2$  is independent of that of EtOH.

R. N. C.

**Rate of fermentation of sugars by different kinds of yeast.** R. GUILLEMET (Compt. rend. Soc. Biol., 1936, 121, 467—469).—The rates of fermentation of sucrose (I) and maltose (II) by "grain" yeasts are the same; yeasts grown on molasses ferment (I) more rapidly than do "grain" yeasts, but attack (II) irregularly and less rapidly than (I). The rate of fermentation of (I) does not vary with the age of the yeast, but that of (II) falls. Bakers' yeasts ferment (I) more rapidly than do brewers' yeasts.

R. N. C.

**Kinetics of alcoholic fermentation of sugars by brewer's yeast.** IV. Specificity. Rates of fermentation of  $\alpha$ - and  $\beta$ -glucose. R. H. HOPKINS and R. H. ROBERTS (Biochem. J., 1936, 30, 76—83).—The initial rates of fermentation attained by  $\alpha$ - (I),  $\beta$ - (II), and  $\alpha\beta$ -glucose (III) are the same except with initial consns. of < 1%, (I) with consns. of 0.5 and 0.25% attaining a max. rate > (II).  $K_m$  vals. for (I) and (II) are respectively 0.0099 and 0.0118. It is suggested that neither (I) nor (II) but an intermediate, probably open-chain, form of glucose is specifically fermented, (I) being converted more rapidly than (II) into this form. Mutarotation of partly fermented (III) may be explained on this hypothesis.

P. W. C.

**Alcoholic fermentation in heavy water.** O. REITZ (Z. physikal. Chem., 1936, 175, 257—274).—By the fermentation of sucrose (I) in pure  $\text{D}_2\text{O}$   $\text{CH}_2\text{D}\cdot\text{CD}_2\cdot\text{OD}$  is formed. With decrease in the D content of the solvent,  $\alpha$ , the proportion of it which is incorporated into the Me group of the alcohol formed, falls. Fermentation of (I) and  $d$ -glucose in pure  $\text{D}_2\text{O}$  is only half as rapid as in ordinary  $\text{H}_2\text{O}$  (cf. A., 1934, 327). The rate of decrease in the rate of fermentation with increase in  $\alpha$  increases with  $\alpha$ .

R. C.

**Metabolic systems involved in dissimilation of carbohydrate reserves in baker's yeast.** T. J. B. STIER and J. N. STANNARD (J. Gen. Physiol., 1936, 19, 479—494).—The endogenous respiration (dissimilation of carbohydrate reserves) of intact yeast cells is a purely respiratory process, fermentation not being involved. Anaërobic  $\text{CO}_2$  production and EtOH production are absent;  $R:Q=1$ , and is unaffected by cons.  $10^{-5}$  to  $10^{-1}M$  of  $\text{CH}_2\text{I}\cdot\text{CO}_2\text{H}$  or KCN. If the structure of the cells is destroyed, fermentation reactions occur.

F. A. A.

**Kinetic analysis of the endogenous metabolism of bakers' yeast.** T. J. B. STIER and

J. N. STANNARD (J. Gen. Physiol., 1936, 19, 461—477).—The endogenous metabolism of *Saccharomyces cerevisiae* placed in a non-nutrient medium shows two phases; (a) a const. rate of  $O_2$  consumption and  $CO_2$  production as long as the stored material is ample, (b) a first-order decline in rate, which  $\propto$  the concn. of some substrate, probably glycogen. R.Q.=1 in both phases; their relative duration depends on the age of the cultures. F. A. A.

**Absorption spectrum of reduced cytochrome from baker's and brewer's yeasts.** E. ELION (Bull. Soc. Chim. biol., 1936, 18, 165—172).—The method of Fink (A., 1932, 1167) for distinguishing between brewer's and baker's yeast is based on the finding that the absorption spectrum of the cytochrome of the former has two, that of the latter four, bands. There are exceptions to this, some brewer's yeasts having a four-banded, some baker's yeasts a two-banded, cytochrome spectrum. A. L.

**Effect of time and intensity of radium radiation on the inverting capacity of yeast.** G. HARKER (Nature, 1936, 137, 190—191).—Exposure of yeast to Ra emanations permanently reduces its sugar-inverting power. The effect reaches a saturation val. depending on the intensity of the radiation, and is due to some action on the living cells rather than on the enzyme itself. L. S. T.

**Polyose of yeast membrane. II.** L. ZECHMEISTER and G. TÓTH (Biochem. Z., 1936, 284, 133—138; cf. A., 1934, 810; Sevag *et al.*, A., 1935, 1280).—The polyose (I) occurs pre-formed in yeast and is obtained when it is degraded by enzymes. (I) is not attacked by  $H_2O$  at  $100^\circ$  but is hydrolysed by dil. acid and alkali. (I) in untreated yeast resists hydrolysis, being protected by impurities. W. McC.

**Isolation of adenosinetriphosphoric acid from yeast.** T. WAGNER-JAUREGG (Z. physiol. Chem., 1936, 238, 129—130).—100 g. of fresh yeast yield 60 mg. of adenosinetriphosphoric acid,  $[\alpha]_D -30.9^\circ$  (as Na salt in  $H_2O$ ), and some inosinepyrophosphoric acid (?). R. S. C.

**Mitogenetic radiations and Liesegang rings.**—See this vol., 426.

**Action of various growth-substances on the growth of certain fungi.** L. RONS DORF (Arch. Mikrobiol., 1935, 6, 309—325).—An apparent selectivity is shown in the response of various fungi to auxin, bios, and to Nielsen's growth-substance-A and -B. Auxin disappears from nutrient solutions whether added before or after sterilisation. Interrelationships between the various growth factors and vitamin-B are discussed. A. G. P.

**Auxogenic action of normal and pathological tissues on the growth of *Phycomyces*.** W. H. SCHOPFER (Compt. rend., 1936, 202, 236—238).—Rabbit liver contained a thermostable,  $H_2O$ - and EtOH-sol. growth-promoting substance, probably vitamin- $B_1$ , which was also present to a smaller extent in a tumour and the EtOH extract. H. G. R.

**Synthesis of vitamin- $B_1$  by *Phycomyces*.** W. H. SCHOPFER and A. JUNG (Arch. Mikrobiol.,

1935, 6, 345—349).—*Phycomyces* grown on a synthetic medium supplemented with vitamin- $B_1$  does not absorb an appreciable amount of the vitamin. Rat tests afford no evidence of the synthesis of - $B_1$  by the mould. *Phycomyces* produces a yeast-stimulating substance and an auxogenic factor. The action of - $B_1$  in stimulating the growth of *Phycomyces* is not a direct one. Its presence is necessary to enable the organism to produce its sp. growth factors. A. G. P.

**Growth factors and vitamins in plants. Effect of extracts of *Aspergillus* on the development of *Phycomyces*.** W. H. SCHOPFER and A. JUNG (Arch. Mikrobiol., 1935, 6, 334—344).—Extracts of several species of *Aspergillus* activate culture media of *Phycomyces*. The active agent is probably vitamin- $B_1$ , which is synthesised in very small quantities by the organism. A. G. P.

**Rôle of bios in the biology of fungi of the genus *Fusarium*.** A. R. WERNER (Compt. rend. Acad. Sci. U.R.S.S., 1935, 4, 61—64).—The presence of bios in the growth medium is essential for sporulation. Low viability and the physiological need of activators induce the fungus to invade living tissues. A. G. P.

**Availability of the nitrogen compounds eliminated by *Aspergillus niger*.** A. RIPPEL and G. BEHR (Arch. Mikrobiol., 1935, 6, 359—361).—N compounds appearing in the substrate of cultures of *A. niger* have little nutrient val. for the fungus. The substances are possibly related to the colouring matter and humin formed during autolysis. A. G. P.

**Absorption of oxalic acid by *Aspergillus repens*.** D. BACH and J. FOURNIER (Compt. rend., 1935, 201, 1416—1417).—In media containing or free from glucose, max. consumption of  $H_2C_2O_4$  occurs at  $p_H$  approx. 3.5 and is nil at  $p_H$  7, indicating utilisation of  $HC_2O_4'$  and not of  $C_2O_4''$ . F. O. H.

**Chemical sterilisation of humus for fungus cultures.** D. LHNELL (Arch. Mikrobiol., 1935, 6, 326—333).—Use of volatile antiseptics (Schweitzer 1932) gives only partial sterilisation. EtOH is the most effective of the substances examined, killing all fungus spores and reducing bacterial nos. to approx. 2%. A. G. P.

**Fungus fluorescence *in vitro*.** A. S. VON MALLINCKRODT-HAUPT and C. CARRIE (Arch. Dermatol. Syphilis, 1934, 169, 519—526).—Cultures of pathogenic skin fungi in sucrose-urea-mineral salt media showed fluorescence *in vitro* after 14 days. Colour changes followed variations in the  $p_H$  of the medium. Fluorescence nearly disappeared at neutrality. CH. ABS. (p)

**Action of micro-organisms on the diastereomeric forms of hexane- $\gamma$ -diol.**—See this vol., 452.

**Formation of organo-metalloidal compounds by micro-organisms. IV.**—See this vol., 460.

**Penicillic acid.**—See this vol., 456.

**Correlation of qualitative microchemical tests on the protozoan nucleus and the mode of nutrition.** M. S. LUCAS and C. A. EVANS (J. Roy. Microscop. Soc., 1935, [iii], 55, 261—264).—Certain

saprozoic protozoa contained no detectable thymonucleic acid or inorg. salts in their nuclei. H. D.

Why have some investigators been unable to grow *Chilomonas paramecium* in inorganic or simple organic solutions? S. O. MAST and D. M. PACE (Science, 1936, 83, 18—19).—Conflicting evidence is discussed (A., 1935, 1027). L. S. T.

Fixation of quinine by *Paramecia* as determined by its fluorescence. G. VALETTE (Compt. rend., 1935, 201, 681—683).—The cytological effect of the drug on *P. caudatum* is similar to that of neutral-red. J. L. D.

Glucose metabolism of trypanosomes (*T. equiperdum* and *T. Lewisi*). L. REINER, C. V. SMYTHE, and J. T. PEDLOW (J. Biol. Chem., 1936, 113, 75—88; cf. A., 1935, 125).—*T. equiperdum* decomposes 1 mol. of glucose anaerobically, forming 1 mol. each of glycerol and  $\text{AcCO}_2\text{H}$  (I). Under aerobic conditions 2 mols. of (I) are formed, together with small amounts of lactic acid and  $\text{CO}_2$ . Presence of serum or plasma does not alter the course of reaction, but increases the rate of the anaerobic process. *T. Lewisi* under anaerobic conditions forms succinic acid,  $\text{AcOH}$ , and  $\text{EtOH}$ , and in addition  $\text{HCO}_2\text{H}$  and  $\text{CO}_2$  under aerobic conditions. There is no evidence that phosphorylation is involved in the metabolism of either species. J. N. A.

Trypanocidal action of azo-dyes. A. ST. G. HUGGETT and S. F. SUFFOLK (J. Pharm. Exp. Ther., 1936, 56, 188—193).—Of the azo-dyes chlorazol-fast-pink B.K.S (I), chlorazol-sky-blue FFS and S.D. 2, all of which have an anticoagulant action, the most highly trypanocidal, as tested by its action on *T. equiperdum* infection in mice, is (I), which is only slightly less active than germanin. Its high toxicity, however, reduces its chemotherapeutic index to 3—7. W. O. K.

Physiology of pigments of purple bacteria. III. Carotenoids. E. SCHNEIDER (Rev. Fac. Sci. Univ. Istanbul, 1936, 1, No. 2, 74—80; cf. A., 1934, 1265).—Two fractions were obtained. One is adsorbed by  $\text{Al}_2\text{O}_3$ ,  $\text{Ca(OH)}_2$ , or  $\text{CaCO}_3$ , and is probably a lipochrome containing O. The second fraction is adsorbed on  $\text{Al}_2\text{O}_3$  or  $\text{Ca(OH)}_2$ , and is probably related to, but is more autoxidisable than, lycopene. Both fractions are mixtures of very similar compounds, probably isomerides. E. P.

Carotenoids of purple bacteria.—See this vol., 340.

Formation of putrescine from *D*-arginine by bacterial action. K. HIRAI (Biochem. Z., 1936, 283, 390—392).—A strain of *B. coli* was used and the base isolated as aurichloride and platinichloride in good yield (7.5 g. of putrescine hydrochloride from 10 g. of arginine hydrochloride). P. W. C.

Lime-precipitating bacillus and an iron- and silica-accumulating coccus as stone formers. A. BRUSSOFF (Arch. Mikrobiol., 1935, 6, 471—474).—The rust-coloured layer found on the sides of conduits for hot spring  $\text{H}_2\text{O}$  in Aachen is formed by two types of bacteria. One ppts.  $\text{CaCO}_3$  and the other

accumulates Fe and  $\text{SiO}_2$ , which collect in a gelatinous condition between the calcareous concretions. A. G. P.

Bacterial proteases. III. Acidoproteolyte of Gorini. G. GORBACH and R. ULM (Arch. Mikrobiol., 1935, 6, 362—368).—Milk, and the casein-containing ppt. produced in skim-milk cultures of *Mammococcus Gorini*, contain a protease of the papain type exhibiting max. activity in neutral media. Proteolysis of casein increases and that of gelatin and peptone decreases with the age of the culture. A peptidase is also present (optimum  $p_{\text{H}}$  4.8) which tends to become less active with the ageing of the prep. A. G. P.

Reduction of methylene-blue by *B. abort. infectiosi*, Bang, and *B. melitense*. K. H. BAU and K. WANG (Z. Hyg., 1935, 117, 399—402).—The organisms reduce methylene-blue in presence of a no. of alcohols and carbohydrates, and also open-chain  $\text{NH}_2$ -acids; the action of *B. melitense* is the stronger. R. N. C.

Influence of dicyanodiamide, guanidine, and guanylurea on bacteria.—See B., 1936, 245.

Effect of metallic salts on lactic acid fermentation. A. ZLATAROV and D. KALTSHEVA (Biochem. Z., 1936, 284, 12—23).—Lactic acid fermentation of milk and whey by *Streptococcus lactis* is restricted by Mn, Co, Ni,  $\text{Fe}^{++}$ , and  $\text{Fe}^{+++}$  salts in concns. > approx. 0.01M ( $\text{Mn} < \text{Fe} < \text{Ni} < \text{Co}$ ), the extent of restriction depending on the concn. of salt. Lower concns. have a slight stimulatory effect. W. McC.

Biological activators of *Azotobacter*. A. R. WERNER (Compt. rend. Acad. Sci. U.R.S.S., 1935, 4, 57—60).—Bios from yeast or from extracts of soil-grown green algae stimulates the fixation of N by *Azotobacter*. A. G. P.

Electrical method for killing bacteria in gaseous suspension. M. PAUTHENIER and H. VOLKRINGER (Compt. rend., 1936, 202, 250—252).—*B. prodigiosus* in air or  $\text{N}_2$  is killed by passage through an electric field maintained by an e.m.f. of the order of 3000 volts per cm. H. G. R.

Bactericidal action of ammonium persulphate. H. LEUNIG (Z. Hyg., 1935, 117, 257—262).—The bactericidal action of dil.  $(\text{NH}_4)_2\text{S}_2\text{O}_8$  solutions is augmented considerably by small quantities of org. acids. R. N. C.

Chemistry of virulence. L. HALLAY (Wien. med. Woch., 1934, 84, 1254—1256; Chem. Zentr., 1935, i, 3800).—The virulence of pathogenic micro-organisms is generally increased by acidification of the inflamed regions, and reduced by restoration of the original  $[\text{H}^+]$  equiv., which can be effected by active hyperemia, sweat-production, antiketogenic diet, and surface inflammation with buffer solutions. R. N. C.

Cultivation of *B. diphtheriae* on telluric media. J. ZOPOTH (Compt. rend. Soc. Biol., 1936, 121, 785—788). R. N. C.

(A) Fibrinolysis by streptococci of human and animal origin. (B) Carbohydrate-fibrinolytic linking in *Streptococcus hemolyticus*. (C) Fibrinolytic streptococci from lower animals.

(D) Susceptibility of "hybrid" fibrins to *Streptococcus* fibrinolysins. R. R. MADISON (Proc. Soc. Exp. Biol. Med., 1934, 31, 1018—1019; 32, 49—50, 444—445, 641—644).—(A) Human plasma clots were liquefied by 94% of cultures of *S. haemolyticus* of internal human origin, by 17% of those from superficial human tissue, and by 7% of those of veterinary origin. Numerous strains of *S. viridans* were non-fibrinolytic.

(B) The Tillet-Garner sp. fibrinolytic titre of strains of *S. haemolyticus* was closely correlated with the Lamefield human-diagnostic "carbohydrate" titre.

(C) Strains of *S. haemolyticus* from horse and hog were sp. lytic for the fibrins of these animals.

(D) Heterogeneous fibrinogen (I)—thrombin (II) complexes vary in susceptibility according to the origin of the (I). Both (I) and (II) from man are carriers of susceptibility to antihuman streptococcus fibrinolytin. Similarly sp. phenomena occur in the horse and hog.

CH. ABS. (*p*)

Production of staphylococcal toxin and anatoxin. G. RAMON (Compt. rend. Soc. Biol., 1936, 121, 375—379).

R. N. C.

Determination of staphylococcal toxin. G. RAMON and R. RICHOU (Compt. rend. Soc. Biol., 1936, 121, 379—382).

R. N. C.

$p_H$  curve of certain smooth strains of tubercle bacilli. R. K. GOYAL (Compt. rend. Soc. Biol., 1936, 121, 390—392).—The curves for seven strains over a period of 10 weeks are described; they are affected by phenolsulphonaphthalein to different extents.

R. N. C.

Chemistry of the tubercle bacillus: lipid compounds. M. FRANCIOSI (R. Ist. lombardo Sci. Lettere, Rend., 1934, 67, No. 2, 737—740; Chem. Zentr., 1935, i, 3943).—Fractional extraction of the living bacilli in the cold yields fat, phosphatides, wax, and C-H-O compounds of high mol. wt. and m.p.

R. N. C.

Nuclear staining of myxobacteria and other species. P. F. MILOVIDOV (Arch. Mikrobiol., 1935, 6, 475—509).—A no. of species show nuclear staining after but not before hydrolysis with HCl. Application of the technique for ascertaining the distribution of nuclear material at various stages of development is described. Thymonucleic acid occurred generally in the organisms.

A. G. P.

Staining and microscopical demonstration of filterable viruses. A. C. COLES (J. Roy. Microscop. Soc., 1935, [iii], 55, 249—255).

H. D.

Isolation of crystalline tobacco mosaic virus protein from diseased tomato plants. W. M. STANLEY and H. S. LORING (Science, 1936, 83, 85).—An active cryst. protein has been obtained from tomato plants infected with tobacco mosaic virus (cf. A., 1935, 1181); it has the same cryst. form and properties as that isolated from tobacco plants.

L. S. T.

Irradiation of plant viruses and micro-organisms with monochromatic light. III. Resistance of the virus of typical tobacco mosaic and *E. coli* to radiations of 3000—3250 Å. A. HOLLAENDER and B. M. DUGGAR (Prac. Nat. Acad. Sci.,

N N

1936, 22, 19—24).—The amount of energy necessary to destroy 50% of the virus at 2250 Å. is 20% of that required at 2650 Å. To inactivate *E. coli* the energy requirement at 2250 Å. is > that at 2650 Å.

A. G. P.

Effect of food and of exhaustion on the pituitary, thyroid, adrenals, and thymus glands of the rat. D. H. ANDERSON (J. Physiol., 1935, 85, 162—167).

R. N. C.

Epiphysis problem. W. A. DEN H. JAGER and J. F. HEIL (Acta Brev. neerl. Physiol., 1935, 5, 32—34; Chem. Zentr., 1935, ii, 242).—Removal of the epiphysis or injection of epiphyseal extracts had no marked effects.

G. H. F.

Enteral absorption of insulin. F. LASCH and E. SCHÖNBRUNNER (Arch. exp. Path. Pharm., 1936, 180, 469—478).—Insulin (20 units) directly introduced into the small intestine of rats produces a significant hypoglycæmia in approx. 25% of the rats used. The % response is increased by admixture of insulin with glycerol, EtOH, serum, saponin, or Hg<sub>2</sub>Cl<sub>2</sub>. Acid but not basic dyes completely protect insulin from inactivation *in vitro* by peptic hydrolysis.

F. O. H.

Biological effects of pineal extract (Hanson). L. G. ROWNTREE, J. H. CLARK, A. STEINBERG, and A. M. HANSON (Science, 1936, 83, 164—165).

L. S. T.

Electrodialysis of oxytocin. N. DAS, B. N. GHOSH, and B. C. GUHA (Z. physiol. Chem., 1936, 238, 131—132).—When electrodialysed, oxytocin moves to the cathode at  $p_H$  9.6, but not at  $p_H$  10, and is, therefore, a base or adsorbed on a basic carrier.

R. S. C.

Action of adrenaline on the respiratory quotient. E. M. BRIDGE and H. R. NOLTIE (J. Physiol., 1935, 85, 334—342).—Continuous intravenous injection of adrenaline in unanæsthetised rabbits reduces the R.Q. to the protein-fat level; the low vals. of liver- and muscle-glycogen suggest a purely glycogenolytic action.

R. N. C.

Comparative variations of blood-sugar and bile secretion due to slow and continuous intravenous injection of adrenaline. E. CHABROL and J. SALLET (Compt. rend. Soc. Biol., 1936, 121, 538—540).—Increase of blood-sugar in dogs is accompanied by a fall in rate of bile secretion. Injection of atophan prior to that of adrenaline has no effect.

R. N. C.

Survival and increase of adrenaline in tissue cultures of adrenal glands from chick embryos. M. R. LEWIS and E. M. J. GELING (Amer. J. Physiol., 1935, 113, 529—533).

R. N. C.

Differential depression of vaso-motor mechanisms by adrenaline. L. C. WYMAN and C. TUM SUDEN (Amer. J. Physiol., 1935, 113, 271—278).

R. N. C.

Effect of adrenaline on the blood-sugar, -lactic acid, and -inorganic phosphorus of completely hypophysectomised dogs. I. L. CHAIKOFF, F. L. REICHERT, L. S. READ, and M. E. MATHES (Amer. J. Physiol., 1935, 113, 306—311).—The increases produced by adrenaline in completely hypophysectomised dogs are < those in normal and control animals.

R. N. C.

Comparison of the effects of sympathin and adrenaline on the iris. W. B. CANNON and A. ROSENBLUETH (Amer. J. Physiol., 1935, 113, 251—258). R. N. C.

Reflex liberation of circulating sympathin. A. C. LIU and A. ROSENBLUETH (Amer. J. Physiol., 1935, 113, 555—559). R. N. C.

Exhaustibility of the sympathin stores. J. A. DYE (Amer. J. Physiol., 1935, 113, 265—270).—The sympathin stores are relatively resistant to exhaustion. R. N. C.

Cortin. I.—See this vol., 473.

Sexual hormones. VII, VIII, XI, XII.—See this vol., 467, 472.

Effect of cortin on sensitivity to narcotics. I. SINDRAM (Acta Brev. neerl. Physiol., 1935, 5, 29—30; Chem. Zentr., 1935, ii, 240).—Adrenalectomised animals are very sensitive to narcotics; administration of cortical hormone restores normal sensitivity. G. H. F.

Action of cortical extracts of the adrenals (eucorton) on muscle-phosphagen in normal and adrenalectomised frogs. S. C. A. MOSCHINI (R. Ist. lombardo Sci. Lettere, Rend., 1934, 67, 695—707; Chem. Zentr., 1935, i, 3561).—Eucorton neither prevents the fall of muscle-phosphagen nor maintains life in adrenalectomised animals. R. N. C.

Relation of the adrenal cortical hormone to nitrogen metabolism in experimental hyperthyroidism. G. A. KOELSCH and E. C. KENDALL (Amer. J. Physiol., 1935, 113, 335—349).—The quantity of cortical hormone (I) administered is apparently the only factor that can modify the effect of thyroxine (II) on N metabolism in the dog. A negative N balance does not necessarily occur as a result of complete cortical excision, but may occur in an adrenalectomised dog given a low maintenance dose of (I); it is produced in such cases by (II). The action of (I) against the effect of (II) on N metabolism is a sparing action, and a negative N balance can be made positive by administration of sufficient (I). R. N. C.

Identity of the pigmenting and corticotropic hormones. A. JORES (Klin. Woch., 1935, 14, 132—133).—The pigmenting hormone of the posterior pituitary is not identical with the corticotropic hormone of the anterior pituitary, only the former being adsorbed by animal C. R. N. C.

Action of the melanophoric hormone on the darkness-adaptation of the human eye. W. BUSCHKE (Klin. Woch., 1934, 13, 1785—1786; Chem. Zentr., 1935, i, 3946).—The injected hormone has no action. A. G. P.

Melanophore hormone of the hypophysis cerebri. E. M. K. GEILING and M. R. LEWIS (Amer. J. Physiol., 1935, 113, 534—537).—The hormone is elaborated by the pars intermedia. R. N. C.

Conditions necessary for the continuous growth of hypophysectomised animals. H. M. EVANS, R. I. PENCHARZ, and M. E. SIMPSON (Endocrinol., 1935, 19, 509—514).—Growth of rats is maintained by aq. alkaline extract of pituitary, but not by extract purified with flavianic acid. R. N. C.

Effect of pitocin, pitressin, and antuitrin on fat tolerance tests. H. BLOTNER (Endocrinol., 1935, 19, 587—591).—Pitocin and pitressin (more active), but not antuitrin or antuitrin-S, prevent increases or cause decreases in plasma-cholesterol in patients following ingestion of a fat meal. R. N. C.

Anterior pituitary. IV. Effect of male hormone preparations on the anterior pituitaries of gonadectomised male and female rats. W. O. NELSON and T. F. GALLAGHER (Anat. Rec., 1935, 64, 129—145). R. N. C.

Effect of injection of pituitary extracts on blood-sugar and the residual chromic index of plasma. M. POLONOVSKI, H. WAREMBOURG, and J. DRIESSENS (Compt. rend. Soc. Biol., 1936, 121, 677—679).—Anterior pituitary extract does not appreciably affect the residual chromic index in normal or abnormal conditions. Posterior pituitary extract also has no effect in the normal subject, but raises blood-sugar (I) in diabetes, and both (I) and the residual chromic index in cancer. R. N. C.

Effect of pituitary (posterior lobe) extract on the urinary flow in non-anæsthetised dogs. A. SAMAAAN (J. Physiol., 1935, 85, 37—46). R. N. C.

Action of extracts of posterior lobe of pituitary on the heart of dogs under normal conditions of circulation. W. ANTOPOL and R. RÖSSLER (Z. ges. exp. Med., 1934, 94, 453—470; Chem. Zentr., 1935, i, 2998). G. H. F.

Effect of posterior pituitary preparations on the colloid osmotic pressure of serum-protein, water and mineral metabolism of dogs. K. YANAGI (J. Pharm. Exp. Ther., 1936, 56, 23—38).—Subcutaneous injections of 20—50 international units of pituitrin and pitressin to dogs cause marked hydræmia with a fall in hæmatocrit, and in *d*, *n*, and total protein of the serum, and an increase in plasma vol. During the period of hydræmia serum-K increases. A. L.

Action of parathormone. II. H. K. GOADBY and R. S. STACEY (Biochem. J., 1936, 30, 269—272; cf. A., 1935, 258).—Since in cases of grossly impaired renal function parathormone (I) does not produce the normal increased urinary P excretion, (I) probably acts directly on the kidneys. The effect on blood-Ca is normal. H. D.

Relation of the parathyroid hormone to the state of calcium in the blood. F. C. McLEAN, B. O. BARNES, and A. B. HASTINGS (Amer. J. Physiol., 1935, 113, 141—149).—The average serum-Ca (I) in normal cats is  $1.15 (\pm 0.07) \times 10^{-3} M$ , and ionisation follows the law of mass action. This relationship also holds over the entire range of (I) vals. from those associated with tetany to the max. (I) produced by parathyroid hormone (II). Plasma-Ca is maintained at normal levels by a regulatory mechanism associated with (II); Ca is reduced by parathyroidectomy and increased by (II). Tetany appears only when (I) falls to  $0.65 \times 10^{-3} M$ , and cannot be further correlated with (I). Hyperparathyroidism occurs when (I) is  $> 1.7 \times 10^{-3} M$ , and leads to death at  $1.17 \times 10^{-2} M$ . Na polyanethanolsulphonate used as

an anti-coagulant does not affect Ca ionisation, and plasma so obtained is not toxic to the frog's heart.

R. N. C.

**Effect of extirpation of the parathyroid and thymus of rats on the development of the gnawing teeth: influence of vitamin-D.** T. VON SPRETER (Z. ges. exp. Med., 1935, 96, 95—115; Chem. Zentr., 1935, i, 3002).—Thymectomy caused no deficiency symptoms in rats at puberty. Growth and Ca metabolism remained normal. Thymectomy with parathyroidectomy produced no defects in teeth. No antagonism between thymus and parathyroid in this respect is apparent.

A. G. P.

**Relationship between the parathyroid glands and sex hormones in tetany.** E. P. McCULLAGH and J. E. KEARNS (Endocrinol., 1935, 19, 532—542).

R. N. C.

**Effect of di-iodotyrosine on the thyroid of the rat.** P. DE FREMERY (Acta Brev. neerl. Physiol., 1935, 5, 35—36; Chem. Zentr., 1935, ii, 241—242).—Normal young rats are unsuitable for testing thyrotropic hormone as their thyroids appear to be exceptionally active. Injection of di-iodotyrosine inhibits this activity and renders the glands suitable for testing.

G. H. F.

**Influence of thyroidectomy on the effectiveness of gonad-stimulating hormones.** S. L. LEONARD and I. B. HANSEN (Anat. Rec., 1936, 64, 203—209).

R. N. C.

**Relationships in the sex hormone groups.** L. RUZICKA (Nature, 1936, 137, 260—262).—A summary.

L. S. T.

**Sex glands, particularly in connexion with the corpus luteum hormone.** K. EHRLHARDT (Münch. med. Woch., 1934, 81, 1838—1840).—A review.

R. N. C.

**Effect of sex hormones on the prostate of monkeys.** S. ZUCKERMAN and A. S. PARKES (Lancet, 1936, 230, 242—247).—Androsterone and androstanediol (I) produce rapid development of the prostate and seminal vesicles of immature rhesus monkeys. When administered in the ratio 50:1, (I), but not progesterone, suppresses the prostatic effects of œstrone.

L. S. T.

**Effect of some gonadotropic hormones on the chick.** W. R. BRENNEMAN (Anat. Rec., 1936, 64, 211—220).

R. N. C.

**Crystalline male hormone from urine.** K. DAVID and J. FREUD (Acta Brev. neerl. Physiol., 1935, 5, 31—32; Chem. Zentr., 1935, ii, 239—240).—Male hormone obtained from urine is probably not identical with that from testes. By reducing the cryst. hormone from urine a substance is formed which is thrice as active on capons as the original crystals.

G. H. F.

**Effect of male hormone on the protein and energy metabolism of castrate dogs.** C. D. KOCHAKIAN and J. R. MURLIN (J. Nutrition, 1935, 10, 437—459).—Injection of the hormone results in a temporary decrease followed by an increase in the amount of urea excreted. Other urinary N constituents are unaffected. Fat metabolism is increased,

that of protein decreased, and that of carbohydrate unaffected in thin but decreased in fat dogs.

A. G. P.

**Effect of the ovarian hormones, œstrin and progesterin, on the menstrual cycle of the monkey.** G. W. CORNER (Amer. J. Physiol., 1935, 113, 238—250).

R. N. C.

**Estimation of œstrin and of male hormone in oily solution.** E. BULBRING and J. H. BURN (J. Physiol., 1935, 85, 320—333).

R. N. C.

**Action of the ovarian hormones on the uterine muscle measured *in vivo* and *in vitro*.** J. M. ROBSON (J. Physiol., 1935, 85, 145—158).

R. N. C.

**Effects of œstrin on the urogenital tract of the male monkey.** G. VAN WAGENEN (Anat. Rec., 1935, 63, 387—403).

R. N. C.

**Excretion of theelin in the urine of guinea-pigs with irradiated ovaries.** I. G. SCHMIDT (Anat. Rec., 1936, 64, 255—266).—Theelin excretion is reduced in irradiated ovaries, which show a normal appearance but have very few follicles. It is excreted from irradiated ovaries in which the œstrous opening is prolonged, in amounts < in normal œstrous urine, but too high to be accounted for by the no. of follicles present; it is probably secreted also by the glandular tissue itself.

R. N. C.

**Hormonal control of œstrus, ovulation, and mating in the female rat.** E. WITSCHI and C. A. PFEIFFER (Anat. Rec., 1935, 64, 85—105).

R. N. C.

**Relation of lipins to œstrin and progesterin in the corpus luteum of the sow.** E. M. BOYD and C. A. ELDEN (Endocrinol., 1935, 19, 599—602).—œstrin in the corpus luteum  $\propto$  phospholipins, whilst progesterin is inversely  $\propto$  free cholesterol; other lipin fractions are not related to the hormone concns.

R. N. C.

**Hormones of the corpus luteum.** A. BUTENANDT and V. WESTPHAL (Ber., 1936, 69, [B], 443—447).—All the remaining ketone mixtures including those of m.p. > 100° and < 145—155° obtained from swine ovary (A., 1934, 1268) are dissolved in  $\text{CHCl}_3$ - $\text{C}_5\text{H}_5\text{N}$  and treated gradually at 0° with a cooled solution of  $\text{ClSO}_3\text{H}$  in  $\text{CHCl}_3$ . The alcohols are thereby converted into the H sulphates, which yield sparingly sol. Na salts; these are decomposed by  $\text{AcOH}$  or  $\text{EtOH}$ - $\text{H}_2\text{SO}_4$ . The material unattacked by  $\text{ClSO}_3\text{H}$  crystallises readily. All the crude crystallisates obtained from ovarian extracts through the semicarbazones are thus shown to be mixtures of *allopregnanolone* (Na sulphate, m.p. about 193°) and  $\alpha$ - or  $\beta$ -progesterone in varying proportion. Indications of the presence of other substances are not observed. Progesterone (I) and pregnenolone (II) can be separated similarly. (II),  $[\alpha]_D^{20} + 30^\circ$  in  $\text{EtOH}$  (oxime, m.p. 218—219°) (cf. A., 1934, 1268), is smoothly transformed into (I) by treatment with Br in  $\text{AcOH}$  at 0° and subsequently with  $\text{CrO}_3$ - $\text{AcOH}$  at 20° followed by Zn dust and  $\text{AcOH}$  at 100°. Treatment of various crystallisates with  $\text{ClSO}_3\text{H}$  shows the presence only of (I) and (II); transformation products are not observed.

H. W.

**Substances stimulating the uterus in the blood of pregnant and parturient women.** F. CAROCA and O. KOREF (*Endokrinol.*, 1935, 15, 244—250; *Chem. Zentr.*, 1935, ii, 238).—Whole blood or serum from men, or from women in the intermenstrual period, stimulates the contraction of the virgin guinea-pig uterus equally. Serum from pregnant, menstruating, and parturient women is one third as potent owing to counteraction by corpus luteum hormone, but whole blood from parturients is much more potent than its serum. The active substance is adsorbed on the fibrin during clotting. G. H. F.

**Action of hormones on the closed vagina.** E. DINGEMANSE and S. E. DE JONGH (*Acta Brev. neerl. Physiol.*, 1935, 5, 27; *Chem. Zentr.*, 1935, ii, 238).—Non-cryst. extracts of follicular fluids and of urines are relatively more effective in causing opening of the vagina of infantile rats than are cryst. preps. Probably the former contain another biologically active substance. G. H. F.

**Action of sex hormones on the prostate and its accessories in the mouse.** S. E. DE JONGH (*Acta Brev. neerl. Physiol.*, 1935, 5, 28; *Chem. Zentr.*, 1935, ii, 240).—Injection of folliculin (especially the benzoate) into young mice causes typical hypertrophy of the anterior lobe of the prostate. Injection of an equiv. amount of male hormone protects the mice against this stimulus; corpus luteum hormone gives no protection. G. H. F.

**Vitamin deficiency as a cause of disease and the vitamin requirements of man.** H. J. JUSATZ (*Z. Volksernähr.*, 1935, 10, 97—99; *Chem. Zentr.*, 1935, i, 3000).—A review. Daily requirements are given for -A, -B<sub>1</sub>, and -B<sub>2</sub> in adults, and -C and -D in infants and adults. G. H. F.

**Vitamin-A, -B, and -C content of raw, boiled, and pasteurised milk.** L. DE CARO and I. SPEIER (*Quad. Nutrizione*, 1935, 2, 171—188).—A daily dose of 3 ml. of raw milk (but not of the treated milks) or 6 ml. of either, provided sufficient vitamin-A for rats. For the -B complex, 10 ml. of all three milks sufficed, but 8 ml. of raw milk was not enough. The ascorbic acid content of raw milk was 4.8—14.5, of boiled milk 1.2—9.7, and of pasteurised milk 1.6—9.2 mg. per litre. NUTR. ABS. (m)

**Relation between vitamin-A and -D intake by the hen and the output in eggs.** W. C. RUSSELL and M. W. TAYLOR (*J. Nutrition*, 1935, 10, 613—623).—11—32% of ingested vitamin-A reappeared in eggs. The -A content of the liver varied inversely with egg production. 10% of ingested -D was transferred to eggs. Sunlight is more effective in increasing the -D content of eggs than is the amount of cod-liver oil given. A. G. P.

**Metabolism of vitamin-A.** A. PRZEŹDZIECKA (*Wiad. farm.*, 1935, 62, 201—203; *Chem. Zentr.*, 1935, ii, 244).—A colorimetric method for determining the vitamin in urine is described. G. H. F.

**Minimum vitamin-A requirements with particular reference to cattle.** H. R. GUILBERT and G. H. HART (*J. Nutrition*, 1935, 10, 409—427).—Vitamin-A requirement may be related to body-wt. rather than to energy requirement. Requirements

per unit body-wt. for chicken and turkeys are > those of mammals. A. G. P.

**Influence of breed and ration on carotene and vitamin-A content of milk.** W. M. BEESON (*Proc. Amer. Soc. Animal Prod.*, 1935, Jan., 54—56).—The carotene (I) content was highest in Guernsey and lowest in Holstein and Ayrshire butters, and the vitamin-A (II) content was highest in Holstein and lowest in Guernsey butters, so that the total (II) potency varied little with different breeds of cows. Large amounts of (I) in the diet increased the (I) and (II) contents of the butters. NUTR. ABS. (m)

**Application of the spectrophotometric method for the characterisation of photo-labile substances by their rate of decomposition.** A. CHEVALLIER and P. DUBOULOZ (*Bull. Soc. Chim. biol.*, 1936, 18, 190—194).—The method is applied to  $\beta$ -ionone and vitamin-A. A. L.

**Determination of vitamin-A.** A. PRZEŹDZIECKA (*Biol. Lekarska*, 1935, No. 6).—A modification of the SbCl<sub>3</sub> method is proposed. If the mixture is heated with guaiacol for 2 min. at 60° a rose or red colour is produced which is stable and may be compared with a standard solution of Sudan 3. NUTR. ABS. (m)

**Determination of vitamin-A.** E. M. HUME (*Nature*, 1936, 137, 277).—A defence of the decisions taken by the International Conference on vitamin standardisation (cf. this vol., 390). L. S. T.

**B-Avitaminosis and detoxication in rabbits.** T. KUMON (*J. Biochem. Japan*, 1935, 22, 213—224).—Conjugation of administered BzOH, CH<sub>3</sub>Ph·CO<sub>2</sub>H, and CH<sub>3</sub>Ph·CH<sub>2</sub>·CO<sub>2</sub>H with glycine is not affected by B-avitaminosis; excretion of BzOH following administration of BzOH of hippuric acid (I) is, however, diminished. The *in-vitro* hydrolysis of (I) by liver and kidney tissue is not affected. Other detoxication processes influenced include formation of ethereal sulphates by PhOH and indole and of indican and methylation of C<sub>5</sub>H<sub>5</sub>N, but not conjugation with glycuronic acid. F. O. H.

**Avian B-avitaminosis and enzyme action.** S. TSUNOO, M. TAKAMATSU, T. KAMACHI, and M. IMAIZUMI (*J. Biochem. Japan*, 1935, 22, 225—231).—The enzymic activities of normal pigeon and fowl tissues vary considerably in individual vals. No significant changes appear to be due to B-avitaminosis but the data indicate a diminished activity of kidney-phosphatase and increased activity of pancreatic esterase and hepatic amylase. F. O. H.

**Utilisation of sugars. Vitamin-B and alimentary equilibrium.** L. RANDOIN and F. MILHAUD (*Compt. rend.*, 1935, 201, 1426—1428).—Death of rats on a diet consisting only of glucose, fructose, sucrose, lactose (I), or especially galactose (II) is more rapid than that from actual starvation (H<sub>2</sub>O only). Compared with vitamin-B-free diets containing these sugars, life is prolonged to > 150 days by addition of -B except with (I) and (II). F. O. H.

**Effect of lack and excess of vitamin-B on the calcium and magnesium content of the tissues of pigeons.** S. MURZA-MURZICZ and H. BOHDANO-

WICZÓWNA (Biochem. Z., 1936, 284, 139—145).—The Ca contents of muscle, heart, and brain, but not liver, are decreased by overdoses of vitamin-B, whilst Mg remains unaffected or is slightly increased. Lack of -B causes increase in Ca and Mg. W. McC.

**Differentiation of the antidermatitis factor.** A. G. HOGAN and L. R. RICHARDSON (Science, 1936, 83, 17—18).—When vitamin-B carriers are exposed to ultra-violet irradiation, at least one member of the -B complex is destroyed, and the preps. cause a severe dermatitis and ultimate death of rats. This destructive action cannot be demonstrated when the diet contains significant amounts of maize starch. EtOH extracts of the starch heal the lesions, indicating that the preventive agent is not identical with -B<sub>2</sub>. L. S. T.

**Vitamins and tissue-diastase in relation to organ function.** F. MAIGNON (Ann. Physiol. Physiochim. biol., 1934, 10, 903—904; Chem. Zentr., 1935, i, 3000).—Diastase from various organs caused no improvement in pigeons suffering from B-avitaminosis or in scorbutic guinea-pigs. G. H. P.

**Vitamin-B complex in the root of the manioc.** F. A. DE MOURA CAMPOS (Ann. Fac. Med. Univ. São Paulo, 1935, 11, 27—31).—Manioc (cassava) meal is a fairly good source of the -B complex. NUTR. ABS. (m)

**Accumulation of the antineuritic vitamin-B in the animal organism.** N. L. JARUSOVA (Problems of Nutrition, Moscow, 1935, 4, No. 4, 98—106).—Tests on pigeons indicate a storage of -B<sub>1</sub>. NUTR. ABS. (m)

**Nitrogen metabolism of birds with vitamin-deficiency polyneuritis.** B. A. LAVROV and N. L. JARUSOVA (Problems of Nutrition, Moscow, 1935, 4, No. 4, 88—98).—Pigeons receiving a vitamin-B<sub>1</sub>-free diet lost more N than those receiving the same amounts of diet which contained the -B<sub>1</sub>. When birds were completely starved addition of 1 g. daily of a -B<sub>1</sub> concentrate did not result in increased N retention. NUTR. ABS. (m)

**Is the occurrence of methylglyoxal in the urine specific for avitaminosis-B?** J. LEHMANN (Skand. Arch. Physiol., 1935, 71, 157—165).—AcCHO is present in the urine of rats deficient in vitamin-B<sub>1</sub> or -B<sub>2</sub>, and also in control animals in small quantities; it is destroyed if the urine is kept for 12 hr. AcCHO in the urine is therefore not sp. for avitaminosis-B<sub>1</sub>. R. N. C.

**Antineuritic vitamin(-B<sub>1</sub>) contents of some oil-rich seeds.** V. ZAGAMI (Quad. Nutrizione, 1934, 1, 284—294; Chem. Zentr., 1935, i, 3949).—Vitamin-B<sub>1</sub> occurs in varying quantities in walnuts, hazelnuts, peanuts, pistachios, and sesame, pine, and sunflower seeds; almonds and olive oil contain none, or only traces. R. N. C.

**Antineuritic vitamin.**—See this vol., 487.

**Growth studies. III. Avitaminosis-B<sub>1</sub> and -B<sub>2</sub> in caecotomised rats. IV. Vitamin-B<sub>1</sub> and -B<sub>2</sub> contents of body tissues of normal and experimental rats.** W. H. GRIFFITH (J. Nutrition, 1935, 10, 667—674, 675—682).—III. Prolonged sur-

vival of rats on vitamin-B<sub>2</sub>-deficient diets is not due to a caecal supply of -B<sub>2</sub>.

**IV. Vitamin-B<sub>2</sub> is stored in the tissues, from which it is not readily lost during feeding of a deficient diet. -B<sub>2</sub> may function, in part, as a tissue constituent.** A. G. P.

**Vitamin-B<sub>2</sub> requirement of poultry.** L. C. NORRIS, G. F. HEUSER, A. T. RINGROSE, H. S. WILGUS, and V. HEIMAN (Proc. 5th World's Poultry Congr. Rome, 1933, 2, 510—520).—The factor essential for growth, hatchability, prevention of a pellagra-like syndrome and of leg and foot paralysis is probably vitamin-B<sub>2</sub>. The latter consists of at least two factors, one preventing paralysis and another necessary for growth. CH. ABS. (p)

**Behaviour of vitamin-B<sub>7</sub> towards various solvents.** E. MONTEVECOHI (Biochem. Terap. sperim., 1935, 22, 143—150; Chem. Zentr., 1935, ii, 244).—The vitamin is insol. in the usual fat solvents. It is extracted completely by 95% and partly by 70% EtOH. G. H. F.

**Influence of ascorbic acid on normal human carbohydrate metabolism.** S. STOICESCO and N. GINGOLD (Bull. Acad. Méd. Roumanie, 1936, 1, 130—132).—Intravenous or oral administration of ascorbic acid (0.24—0.50 g.) lowers the fasting blood-sugar and diminishes alimentary hyperglycaemia. F. O. H.

**Crystalline vitamin-C: its effects on the capillary fragility.** I. S. WRIGHT and A. LILLENFELD (Arch. Int. Med., 1936, 57, 241—274).—A capillary-fragility test for diagnosing human vitamin-C deficiency is described. The val. of ascorbic acid in various diseases is discussed. H. G. R.

**Effect of ascorbic acid on the proliferation of monocytes.** L. E. BAKER (Compt. rend. Soc. Biol., 1936, 121, 427—429). R. N. C.

**Cystine and vitamin-C deficiency.** L. DE CARO and W. BELTRAMI (Quad. Nutrizione, 1935, 2, 165—170).—Death of guinea-pigs on a scorbutic diet is greatly accelerated by cystine (I) or HCl. Ascorbic acid counteracts the effects of (I). NUTR. ABS. (m)

**Effect of diphtheria toxin on the vitamin-C content of guinea-pig tissues.** C. M. LYMAN and C. G. KING (J. Pharm. Exp. Ther., 1936, 56, 209—215).—Subcutaneous administration of diphtheria toxin to guinea-pigs rapidly lowers the vitamin content of the tissues, especially adrenals, kidney, and pancreas. W. O. K.

**Fixation of ascorbic acid in the adrenal and the liver of the scorbutic guinea-pig. Determination of the minimum curative dose of l-ascorbic acid.** V. DEMOLE and F. IPPEN (Compt. rend. Soc. Biol., 1936, 121, 687—689).—The daily min. dose is slightly < 0.5 mg. for an animal of 250 g. wt. The ingested ascorbic acid is stored in the adrenals, but not in the liver. R. N. C.

**Ascorbic acid in course of cadaverisation.** A. GIROUD, R. RATSIMAMANGA, M. RABINOWICZ, and E. HARTMANN (Compt. rend. Soc. Biol., 1936, 121, 739—740).—Ascorbic acid decreases slowly in the rat and the guinea-pig during cadaverisation; the rate of fall in the adrenals is > in the liver and kidney. R. N. C.

**Secretion of ascorbic acid by the healthy and diseased organism.** H. SCHROEDER (Klin. Woch., 1935, 14, 484—487; Chem. Zentr., 1935, i, 3001).—Ascorbic acid administered to healthy individuals, but not in various pathological conditions, is excreted in increased amounts in the urine, although the vitamin metabolism may be  $>$  normal. G. H. F.

**[Distribution of] ascorbic acid.** A. GIROUD and C. P. LEBLOND (Bull. Soc. Chim. biol., 1936, 18, 173—175).—By the use of acidified aq.  $\text{AgNO}_3$ , ascorbic acid is detected in the thymus, lymphatic ganglia, intestines, liver, sympathetic ganglia, suprarenal medulla and cortex, corpus luteum, ovaries, and pituitary. A. L.

**Vitamin-C in fresh-water fish and crabs.** G. VON LUDÁNY (Biochem. Z., 1936, 284, 108—110).—Data for various tissues are tabulated. In some cases the amounts exceed those found in warm-blooded animals. W. McC.

**Ascorbic acid in the lens of the eye.** H. VON EULER and M. MALMBERG (Arch. Augenheilk., 1935, 109, 225—234).—Indophenol titration of vitamin-C in the eye lens of animals revealed high vals. for sea fish, and -C was detected in the ox, rabbit, horse, and guinea-pig. While the animal received a -C-deficient diet, the -C content of the eye lens fell in guinea-pigs but not in rabbits. The -C content of the lens in rabbits was uninfluenced by high doses of -C. The reducing capacity of the lens in the rat was largely due to glutathione, the -C content being  $<$  in most cases investigated. No marked variation was detected in the -C content of the lens in rats fed on a -B<sub>2</sub>-deficient diet. The -C content of the human lens in cataract was  $<$  normal. Attempts to induce cataract in rabbits by  $\text{C}_{10}\text{H}_8$  poisoning were unsuccessful and the poisoning did not affect the -C content of the lens. Possibly part of the -C in the lens is synthesised there. NUTR. ABS. (m)

**Vitamin-C in the lens and aqueous humour in human cataract.** B. NAKAMURA and O. NAKAMURA (Arch. Ophthalmol., 1935, 134, 197—200).—A diminution was observed. NUTR. ABS. (m)

**Relative vitamin-C values of milk and curd.** A. R. GHOSH and B. C. GUHA (Indian Med. Gaz., 1935, 70, 382).—The vitamin-C content of curd was the same as that of the original milk, even though the curdling process was carried out for 24 hr. at 35°. In fresh milk stored at 0° for 24 hr., there was considerable loss of -C. There appeared to be no synthesis of -C by the lactic acid bacillus employed. NUTR. ABS. (m)

**Milk as a source of vitamin-C.** C. H. WHITNAH and W. H. RIDDELL (Science, 1936, 83, 162).—The milk of four major dairy breeds of cow gave an average val. of  $25.9 \pm 4.3$  mg. per litre. L. S. T.

**Vitamin-C in brain and cerebrospinal fluid.** Effect of diet on the vitamin-C content of the fluid: examination of the fluid in diagnosis of latent scurvy. F. PLAUT and M. BÜLOW (Z. ges. Neurol. Psychiat., 1935, 152, 84—97, 324—336).—The vitamin-C content of the brain in newly born or foetal rabbits and mice was 2—3 times  $>$  in the mother. In human cadavers the -C val. for the brain fell

steadily from foetus to 60—80 years of age. The same tendency was observed in the cerebrospinal fluid, but the concn. was always  $<$  in brain. The concn. in serum did not appear to decline with age. Daily treatment with 90 mg. of -C caused slow progressive rise in the -C content of the fluid of patients and a similar relationship between -C content of food and fluid was observed in rabbits.

NUTR. ABS. (m)

**Histochemistry. V. Vitamin-C concentration of the corpus luteum with reference to the stage of the oestrus cycle and pregnancy.** G. R. BISKIND and D. GLICK (J. Biol. Chem., 1936, 113, 27—33; cf. A., 1935, 1264).—The fully developed corpus luteum of the cow contained 1.4 mg. of vitamin-C per g. of tissue, which decreased to 0.3 mg. with regression. In gestation the content of -C remained at 1.5—2.2 mg. per g. for the first 7 months and decreased to 1.1 mg. in the 8th month. -C may be related to progesterone. J. N. A.

**Determination of vitamin-C and the influence of technological treatment on its preservation in cabbage.** S. G. VINOKUROV, M. M. EIDELMAN, and M. L. BUTOM (Kharkov State Med. Inst. Jubilee J., 1935, 142—161).—Food extracts should always be treated with  $\text{H}_2\text{S}$  before titration with indophenol in vitamin-C determinations. 40—70% of the -C content passed into  $\text{H}_2\text{O}$  when cabbage was cooked for 30 min. Cooking for longer periods involved heavy losses of -C. NUTR. ABS. (m)

**Provitamin-D of heat-treated cholesterol.** M. L. HATHAWAY and D. E. LOBB (J. Biol. Chem., 1936, 113, 105—110).—The provitamin of crude cholesterol (I) is destroyed by purification through the dibromide. When purified (I) is heated at 200° for 2 hr. its proantirachitic activity is increased. It is concluded that irradiation of heat-treated (I) produces a new form of vitamin-D which more closely resembles natural -D from cod-liver oil than -D of irradiated ergosterol. J. N. A.

**Evaluation of the antirachitic vitamin in comparison with the international standard.** M. PODZIMKOVÁ-RIEGLOVÁ (Trav. Inst. Hyg. publ. Tchecosl., 1935, 6, 20—30).—The degrees of calcification of the head of the radius produced by 0.4, 0.2, 0.1, and 0.05 international units of vitamin-D daily, and that observed in control rats receiving no -D are recorded. 0.4 unit was not always sufficient to produce normal calcification. After keeping for 13 months at -5° the activity of the international standard had not diminished. NUTR. ABS. (m)

**Size and structure of the thyroid gland of the cat after the administration of irradiated ergosterol.** A. M. LANDS and O. O. STOLAND (Endocrinol., 1935, 19, 701—704). R. N. C.

**Calcium, inorganic phosphorus, and serum-phosphatase in normal animals and in animals influenced by irradiated ergosterol.** S. FREEMAN and C. J. FARMER (Amer. J. Physiol., 1935, 113, 209—220).—Toxic doses of irradiated ergosterol (I) increase serum-Ca and/or -P, and proportionately decrease serum-phosphatase (II) in dogs and rabbits. (II) is decreased by bleeding and a high-protein diet,

and increased by a high-carbohydrate diet; the increase is enhanced by sub-toxic doses of (I). (II) activity is probably inversely  $\propto$  acid-sol. org. P of the whole blood. R. N. C.

Isolation from wheat-germ oil of an alcohol,  $\alpha$ -tocopherol, having the properties of vitamin-E. H. M. EVANS, O. H. EMERSON, and G. A. EMERSON (J. Biol. Chem., 1936, 113, 319—332).—The unsaponifiable matter yielded (?)  $\beta$ -amyirin allophanate, m.p. 250°, the allophanate, m.p. 138°, of an alcohol,  $C_{29}H_{50}O_2$ , and the allophanate, m.p. 158—160°, of  $\alpha$ -tocopherol (I),  $C_{29}H_{50}O_2$  (p-nitrophenylurethane, m.p. 129—131°). (I) has a characteristic absorption band at 298  $m\mu$ , and treatment with MeOH-AgNO<sub>3</sub> yields a substance with bands at 271 and 262  $m\mu$ . A single dose of 3 mg. of (I) enables vitamin-E-deficient rats to bear young. H. G. R.

Kinetics of penetration. XII. Hydrogen sulphide. A. G. JACQUES (J. Gen. Physiol., 1936, 19, 397—418).—The rate of entry of total sulphide ( $H_2S + S''$ ) into *Valonia macrophysa* is, during the first 5 min.,  $\propto$  external concn. of mol.  $H_2S$ .  $H_2S$  thus differs from  $NH_4^+$  and guanidine (cf. A., 1935, 671, 1179). The mode of entry appears to be diffusion of mol.  $H_2S$  through the cell wall; the rate deviates from a unimol. law. F. A. A.

Amylogenic capacity and organic matter of plastids. A. MAIGE (Compt. rend., 1935, 201, 1411—1414).—The relation of starch formation in potatoes, beans, etc. to the structure, constituents, and developments of starch plastids is discussed. F. O. H.

Transport in the cotton plant. III. Independence of solute movement in the phloem. T. G. MASON, E. J. MASKELL, and E. PHILLIS. IV. Simultaneous movement of solutes in opposite directions through the phloem. E. PHILLIS and T. G. MASON (Ann. Bot., 1936, 50, 23—58, 161—174; cf. A., 1934, 707).—III. Movements of carbohydrates (I), N, P, K, and Ca in petioles and stems of cotton plants, and the effects of ringing, are examined. Results are discussed in the light of current conceptions of the transport of solutes in plants.

IV. Examination of ringed and unringed plants grown in culture solutions shows that (I) and N may movesimultaneously and in opposite directions through the phloem. A. G. P.

Influence of light on the permeability of plant tissues to sugar. L. BRAUNER and M. BRAUNER (Rev. Fac. Sci. Univ. Istanbul, 1936, 1, No. 2, 58—73; cf. A., 1935, 671).—The action of light probably causes a loss of electric charge in the electro-negative membrane cells, and a shrinking.  $H_2O$  or solutions of salts having a dipole moment find less resistance on passing the membranes, whilst compounds having no dipole moment are hindered. E. P.

Effect of light intensity on manganese content of plants. M. M. MCCOOL (Contr. Boyce Thompson Inst., 1935, 7, 427—437).—Visible injury to plants due to the addition of  $MnSO_4$  to soil decreased with the prevailing intensity of light. The % of Mn in leaves decreased, and, in some cases, that of stems increased, with declining light intensity. A. G. P.

Chemical restoration in *Nitella*. II. Restorative action of blood. W. J. V. OSTERHOUT (J. Gen. Physiol., 1936, 19, 423—425; cf. A., 1935, 1038, 1289).—The "K effect" in *Nitella* is restored by exposure to Ca-free blood-plasma (human, cat, calf, sheep). F. A. A.

Effect of potassium chloride on diurnal changes of carbohydrates of the potato leaf. D. J. WATSON (Ann. Bot., 1936, 50, 59—83).—Diurnal fluctuations in sucrose contents of leaflets were  $>$  those of reducing sugars. The rate of removal of dry matter (but not of carbohydrates) during darkness was increased by applications of KCl. KCl probably increases the efficiency of photosynthesis. The  $H_2O$  content per unit of dry matter was increased by KCl and the increase did not vary with time. A. G. P.

Action of radium emanation on the germination of grains. M. DE CARAMAN and C. CHAMPY (Compt. rend. Soc. Biol., 1936, 121, 750—752).—The % germination is increased, and early growth is accelerated. R. N. C.

Energy balance of carbonic acid assimilation [by plants]. K. WOHL (Z. physikal. Chem., 1935, B, 31, 152—156).—Energy considerations show that it is impossible that  $CH_2O + 2H_2O_2$  should be the intermediate product in the assimilation. The Franck-Willstätter-Stoll theory of the mechanism of  $CO_2$  assimilation (A., 1933, 326, 577; A., 1935, 794) is therefore untenable. R. C.

Amino-acid content of plants at different stages of growth. A. I. VIRTANEN and T. LAINE (Nature, 1936, 137, 237).—The tryptophan and aspartic acid contents of peas and clover vary considerably during different stages of growth, indicating that the ratio of various proteins changes during growth, or that in the growing plant the protein has no fixed composition, new  $NH_2$ -acid groups being continuously incorporated with the growing protein mol. L. S. T.

Nitrogen metabolism of the apple fruit. II. Course followed by certain nitrogen fractions during the development of the fruit on the tree. A. C. HULME (Biochem. J., 1936, 30, 258—268; cf. A., 1935, 422).—Non-protein-N was separated from the peel and pulp of apples by extraction with aq. EtOH and determined as total sol., free  $NH_3$ ,  $NH_2$ , and residual N. Titratable acid was also determined. The changes in these fractions during the course of development of two series of fruits was determined. The two series showed similar trends; an early stage of rapid increase in sol. N compounds was followed by a stage of relative equilibrium between protein and non-protein compounds. When mature a state of net synthesis of protein ensued. H. D.

Nitrogen-free aliphatic compounds as organic nutrients of algæ. H. MEYER (Biochem. Z., 1936, 283, 364—381).—The effect of 0.2% of 90 org. substances on the growth of *Chlorella luteoviridis*, as measured by increase in cellular vol. or dry wt. or intensity of division, in a medium containing  $MgSO_4$ ,  $CaCl_2$ ,  $FeCl_3$ ,  $(NH_4)_2HPO_4$ , and phosphate buffer is investigated. With saturated acids, alcohols, and

aldehydes, the first member of the series ( $\text{HCO}_2\text{H}$ ,  $\text{MeOH}$ ,  $\text{CH}_2\text{O}$ ) is toxic, the second member has the highest nutritive val. and the higher homologues are utilised to a decreasing content. *iso*-Acids and unsaturated acids are toxic.  $\beta$ -Hydroxybutyric acid and  $\text{CH}_3\text{Ac}\cdot\text{CO}_2\text{H}$  are readily utilised. Polybasic and sugar acids are indifferent. Hexoses form the best source of C, pentoses are not utilised, polysaccharides are used according to the ease of hydrolysis, whilst methylglucoside and glycerophosphoric acid are indifferent.

P. W. C.

**Fat metabolism in plants with special reference to sterols.** P. L. MACLACHLAN (J. Biol. Chem., 1936, 113, 197—204).—The sterol and fatty acid constituents of soya beans during germination in the light and dark were determined. A decrease in the fat content occurred during germination accompanied by a continuous synthesis and esterification of sterol. Small differences in the behaviour in the light and dark were observed.

H. D.

**Nitrogen fixation by the alder.** A. I. VIRTANEN and S. SAASTAMOINEN (Biochem. Z., 1936, 284, 72—85).—Since peas inoculated with N-fixing bacteria grow normally in an aerated N-free aq. medium it follows that there is no difference in this respect between leguminous plants and the alder. Inoculated alder seedlings grow better in N-free media than do non-inoculated in media containing  $\text{NH}_4\text{NO}_3$ ; the growth of the former is optimal at  $p_{\text{H}}$  6. Inoculated alder enables pine seedlings planted in the same N-free medium to grow normally and appears to give up N compounds to the medium.

W. McC.

**Interaction of factors in the growth of *Lemna*.** VII. Effect of potassium on growth and multiplication. H. L. WHITE (Ann. Bot., 1936, 50, 175—196).—Mathematical relationships between the [K] of the nutrient and the growth of *Lemna minor* are established. Deficiency of K is associated with high starch and dry matter contents per unit area, low rates of assimilation, and diminished amyolytic activity.

A. G. P.

**Supply of iron to plants in water cultures.** W. SCHROPP (Z. Pflanz. Dting, 1936, 42, A, 35—42).—In media containing  $\text{FeCl}_3$ , the accumulation of Fe by plants was inversely related to the reaction of the nutrient. When  $\text{Fe}^{\text{III}}$  citrate was used, growth was improved and the Fe intake was independent of  $p_{\text{H}}$ .

A. G. P.

**Skatole as a growth-promoting substance.** J. GLOVER (Nature, 1936, 137, 320—321).—Experiments with young oat shoots indicate that skatole (I) acts as a growth-promoting hormone. (I) and  $\beta$ -indolylacetic acid are both markedly light-sensitive.

L. S. T.

**Growth-promoting substance at the base of the oat coleoptile.** H. SÖDING (Ber. deut. Bot. Ges., 1935, 53, 843—846).—The growth hormone is present in the base of the coleoptile. No evidence was obtained of a "bound" or inactive form.

A. G. P.

**Absorption and movement of synthetic growth-substances from soil as indicated by responses of aerial parts [of plants].** A. E.

HITCHCOCK and P. W. ZIMMERMAN (Contr. Boyce Thompson Inst., 1935, 7, 447—476).—Application of heteroauxin, indolyl- or phenyl-propionic acids, naphthyl- or phenyl-acetic or indolylbutyric acid to soil induced responses in tomato and tobacco plants similar to those obtained by treatment of the aerial parts of the plants. The rate of absorption of active substances was influenced by the amount present in the soil and by the transpiration rates of the plants. The action of growth-substances (I) applied to aerial parts is not affected by transpiration rates. Within the plant translocation of (I) in living tissue was > in dead tissue and upward > downward movement. Strictly polar movement was not observed in either stems or leaves. Unilateral lighting favoured the bending-response of stems to (I) but light was not essential. Addition of (I) to soil hastened flowering without retarding vegetative growth. The optimum dosage for flowering was < that for root initiation.

A. G. P.

**Response of roots to "root-forming" substances.** P. W. ZIMMERMAN and A. E. HITCHCOCK (Contr. Boyce Thompson Inst., 1935, 7, 439—445).—Application of lanoline preps of  $\alpha$ -naphthyl-, indolyl-, and phenyl-acetic acids, indolyl-butyric, -propionic, and -valeric acids to aerial roots of *Cissus sicyoides*, L., var. *Jacquini*, caused the initiation of new root branches, inhibition of growth of the tip and/or swelling of the root. New rootlets ceased to grow when the main tip resumed elongation, but recommenced on a second treatment of the tip. The dominance of the tip disappeared when the treated area was immersed in  $\text{H}_2\text{O}$ . Results are discussed in relation to the movement of growth-substance in roots.

A. G. P.

**Selenium in native range plants occurring on soils derived from Permian or Triassic (?) sediments [of the Chugwater formation, Albany Co., Wyoming].** O. A. BEATH (Science, 1936, 83, 104).

L. S. T.

**Natural poisoning of hens by acid sorrel (*Rumex acetosella*): poisoning by oxalic acid and potassium hydrogen oxalate.** C. ORLANDINI (Boll. Soc. Eustach., 1933, 31, 217—229).—Poisoning by the sorrel is attributable to  $\text{H}_2\text{C}_2\text{O}_4$  and  $\text{KHC}_2\text{O}_4$ .

CH. ABS. (p)

**Compounds of hydroxylamine in fresh leaves of higher plants.** M. LEMOIGNE, P. MONGUILLON, and R. DESVEAUX (Compt. rend., 1935, 201, 1437—1439).—Distillation of the juice of fresh leaves of *Poa pratensis* yields  $\text{NH}_2\text{OH}$  (1—2 mg. per litre);  $\text{NH}_2\text{OH}$  probably participates in the N metabolism of higher plants.

F. O. H.

**Excretion of amino-acids from root nodules and their chemical nature.** A. I. VIRTANEN, T. LAINE, and S. VON HAUSEN (Suomen Kem., 1936, 9, B, 2).—The rate of excretion is greatest at an early stage of growth, before blooming. A cold- $\text{H}_2\text{O}$  extract of the sand on which peas had grown contained exclusively  $\text{NH}_2\text{-N}$ . About 50% of the total N was due to aspartic acid, while the remainder was probably lysine (I). Barley will grow with (I) as sole source of N.

J. N. A.

Glutamine and asparagine in tobacco leaves. H. B. VICKERY and G. W. PUCHER (J. Biol. Chem., 1936, 113, 157—160).—Glutamine (I) occurs, as well as asparagine (II), in the leaves of the tobacco plant, and may be extracted. Of the total amide-N, (II) appears to account for about  $\frac{2}{3}$ , (I) for about  $\frac{1}{3}$ , but other amide substances may be present. F. A. A.

Biologically active substances in the fruit of the tomato (*Solanum esculentum*) with histamine-like action. Therapeutic action of fresh vegetable juice. F. GLEICHMANN (Z. klin. Med., 1934, 127, 111—131; Chem. Zentr., 1934, ii, 3982).—The cryst. substance extracted from green or ripe tomatoes or conserve is stable to heat, pepsin, and HCl, and resembles histamine in its pharmacological action. R. N. C.

Chemical examination of Punar-Nava (*Bærrhaavia diffusa*, Linn.). R. R. AGARWAL and S. DUTT (Proc. Acad. Sci. U.P. India, 1935, 4, 73—76).—Boiling EtOH extracts *bærrhaavic acid*,  $C_{10}H_{18}O_3$ , m.p. 108—109° (decomp.) (Pb salt;  $Br_3$ -derivative, m.p. 73°), tannins, phlobaphens, and glucose from the entire plant. J. L. D.

Chemical examination of the roots of *Citrullus colocynthis*, Schrader. R. R. AGARWAL and S. DUTT (Proc. Acad. Sci. U.P. India, 1935, 4, 295—300; cf., J.C.S., 1910, 47, 99).—Boiling EtOH extracts  $\alpha$ -elaterin (0.2%); m.p. 229—230° [ $Ac_2$  derivative, m.p. 122—123° (cf. A., 1907, i, 230)], hentriacontane (?), saponins, and reducing sugars from the powdered roots. J. L. D.

2':6'-Dihydroxy-4'-methoxy- $\beta$ -phenylpropio-phenone from the essential oil of *Populus balsamifera*, L. A. GORIS and H. CANAL (Compt. rend., 1935, 201, 1435—1437).—The oil from the buds yields the above ketone, m.p. 168°. F. O. H.

Localisation of rotenone in derris root. P. A. VAN DER LAAN (Pharm. Weekblad, 1936, 73, 313—318).—Cells containing rotenone (I) are coloured green (transient) when treated with  $HNO_3$  and then with  $NH_3$ , and the colour produced on samples of derris root may be used as a rough measure of the (I) content. The (I) is localised in the parenchyma and pith cells present in both the wood and the bast. S. C.

Constituents of *Hamamelis virginica*. F. MERCIER and J. BALANSARD (Compt. rend. Soc. Biol., 1936, 121, 671—672).—The leaves contain choline, an acid saponin, and a sol. glucoside fraction. R. N. C.

Acid saponin of beetroot juice. K. SMOLEŃSKI (Rocz. Chem., 1935, 15, 554—564).—A review. R. T.

Sterols of *Achillea millefolium*. O. GISVOLD (J. Amer. Pharm. Assoc., 1935, 24, 1071).—The sterols consist of sitosterol and stigmasterol (cf. A., 1933, 1216). E. H. S.

Phytosterol and resin of *Fabiana denudata*, Miers. L. FLORIANI (Rev. Centr. Estud. Farm. Bioquim., 1934, 25, 60—62; Chem. Zentr., 1935, i, 3569).—A phytosterol,  $C_{27}H_{46}O$ , a resin, m.p. 44°, an  $\alpha$ -resin-acid, m.p. 37°, and a  $\beta$ -resin-acid, m.p. 39°, are isolated. H. N. R.

Sterols in the leaves and flowers of the lily. M. MIRANDE (Compt. rend., 1936, 202, 238—240).—The distribution of sterols in species of lily is examined. H. G. R.

Determination of carotene and xanthophyll.—See this vol., 493.

Lycoxanthine and lycophyll.—See this vol., 452.

Occurrence of carotenoids in plants. P. KARRER, F. RÜBEL, and F. M. STRONG (Helv. Chim. Acta, 1936, 19, 28—29).—Treatment of the seeds of *Passiflora coerulea* with EtOH followed by boiling  $CHCl_3$ , evaporation of the  $CHCl_3$ , and crystallisation of the residue from ligroin (b.p. 60—80°) gives lycopene in considerable amount.  $\beta$ -Carotene and zeaxanthin are obtained cryst. from *Halyserys polypodioides* but homogeneous fucoxanthin could not be isolated. H. W.

Colouring matters of violet potatoes.—See this vol., 480.

Colourless compounds which accompany carotenoids in plants. L. ZECHMEISTER and P. TUZSON (Z. physiol. Chem., 1936, 238, 204—209; cf. Euler *et al.*, A., 1908, ii, 724; 1930, 1627; 1932, 785).—100 kg. of carrots yield 1.06 g. of daucosterol (I),  $C_{35}H_{60}O_6$ , decomp. at 305°,  $[\alpha]_D^{20}$  —49.6° in  $C_5H_5N$ , hydrolysed by acid to *d*-glucose and sitosterol. The sepals of the sunflower contain a dihydric sterol *helisterol*,  $C_{26}H_{44}O_2$ , m.p. 242°,  $[\alpha]_D^{20}$  +45.4° in  $CHCl_3$  (diacetate, m.p. 166—167° (corr.),  $[\alpha]_D^{20}$  +58.7°), a monohydric sterol, m.p. 217°,  $[\alpha]_D^{20}$  +42.8° in  $CHCl_3$ , a sterolin,  $C_{33}H_{56}O_6$ , m.p. 303°,  $[\alpha]_D^{20}$  —50.5° in  $C_5H_5N$ , which gives glucose and a sterol,  $C_{27}H_{46}O$ , m.p. 159°,  $[\alpha]_D^{20}$  —49.9° in  $CHCl_3$  on acid hydrolysis, an alcohol,  $C_{21}H_{50}O$ , m.p. 73° (corr.), and hentriacontane. W. McC.

Formation of anthocyanins in plants. R. ROBINSON (Nature, 1936, 137, 172—173).—A summary. L. S. T.

Glycosides of the flowers of *Linaria vulgaris*.—See this vol., 458.

Inulinogenesis in the *Compositæ*. H. COLIN (Compt. rend., 1935, 201, 1414—1416).—Data for the contents of reducing sugar, sucrose, and inulin (I) and for  $[\alpha]$  before and after hydrolysis are given to illustrate the discussed formation of (I) in the root, stem, leaf, and wood of various *Compositæ*. F. O. H.

Determination of starch in plant tissue, particularly apple fruit. C. S. HANES (Biochem. J., 1936, 30, 168—175).—After a preliminary extraction of the tissue with 70—80% EtOH the residue is boiled with dil. HCl-EtOH which renders the starch (I) sol. in hot  $H_2O$ . The  $H_2O$  extract is then hydrolysed by  $\beta$ -malt-amylase (II), which produces maltose (III) as almost the only reducing product. The degradation of (I) by (II) proceeds to a definite "hydrolysis limit" The amount of (III) formed is determined either by an alkaline  $Fe(CN)_6^{4-}$  or a Cu method. Apple-(I) is hydrolysed to the same extent by (II) throughout the season, with the production of 0.6 mg. of (III) per mg. of (I), much the same val. as for potato-(I). The (I) content of apples on storage falls nearly to zero in 10 days. If taka-diastase (IV) is used

instead of (II) the apparent (I) content is much higher and falls after 10 days to 1.5 mg. per g. This is due to non-(I) fractions hydrolysed by (IV) but not by (II), some of which are not metabolised, and so persist during storage. Methods are given for the prep. of (II) and control (I) from apples. E. A. H. R.

**Polysaccharides in sweet maize.** M. W. PARRKE (Plant Physiol., 1935, 10, 713—725).—Electrodialysis of the sol. polysaccharide fraction yields an anodic fraction and a further non-migratory fraction. With advancing maturity of the grain, the physical and chemical properties of the fractions approach more closely to those of  $\alpha$ - and  $\beta$ -amylose, and differ from those of dextrin. In maize the sol. polysaccharides may form the units from which starch grains are ultimately formed. A. G. P.

**Polysaccharides of *Iridaea laminarioides*.** II. T. TADOKORO, K. YOSHIMURA, and M. YANASE (J. Chem. Soc. Japan, 1935, 56, 188—191; cf. A., 1935, 268).—Hydrolysis of the product obtained by extraction with hot  $H_2O$  and pptn. with 70% EtOH yielded galactose and smaller amounts of glucose, fructose, and arabinose. The fraction not pptd. by EtOH contained an unidentified sugar having  $[\alpha]_D^{20} +31.4^\circ$ , and yielding a phenylosazone, m. p. 125—130°. CH. ABS. (p)

**Hai-jen-tsao (*Digenia simplex*, Ag).** C. F. HSÜ (Science [China], 1934, 18, 1418—1437).—This marine alga is used as a vermifuge. Alginic acid, extracted by 2%  $Na_2CO_3$ , contains uronic and either glycuronic or mannuronic acids. The boiling- $H_2O$  extract yields galactan, *d*-pararabin, and small amounts of alkaloid and fucoidin. The I content is 0.20%. CH. ABS. (p)

**Isolation of pectic substances from wood.** E. ANDERSON (J. Biol. Chem., 1936, 112, 531—539).—The sap-wood and cambium of *Robinia pseudacacia*, L., yield < 3% and < 13%, respectively, of pectic substances (yielding *d*-galacturonic acid but no methylpentoses), probably present largely as Ca pectate, protected by later deposition of other materials. R. S. C.

**Vegetable chitin.** J. M. DIEHL (Chem. Weekblad, 1936, 33, 36—38).—Analytical data, including determinations of Ac, show that animal and vegetable chitins from *Crangon vulgaris*, *Amanita muscaria*, and *Phycomyces Blakesleeanus* are identical. Like other chitins, that from *Lycoperdon gemmatum* gives AcOH and not  $HCO_2H$  on hydrolysis. S. C.

**Irritant principle in *Mimosoideae*.** A. SOLTYS and K. UMRATH (Biochem. Z., 1936, 284, 247—255).—Fractionation of aq. extracts of *Mimosa* or *Neptunia plena* leaves (4 kg.) by Hg and Pb acetates,  $C_5H_5N$ , EtOH, and  $Ba(OH)_2$  yields 10 mg. of a highly irritant (as indicated by plant movements) OH-acid of high O content, equiv. wt. 250, and mol. wt. 500. The activity is destroyed on acetylation but returns on subsequent hydrolysis. F. O. H.

**Digitalis.** I. New principles in evaluation. B. NIELSEN (Acta med. scand., 1935, 84, 315—354; Chem. Zentr., 1935, i, 3162—3163).—A biological method, employing the toxicity of digitalis preps. for mice, is described. H. N. R.

**Decomposition of nicotine by the fermentation of tobacco.** W. WEBER (Mitt. Lebensm. Hyg., 1935, 26, 214—249).—Aëration of moist tobacco or its  $H_2O$  extract leads to loss of nicotine (I) by decomp. as distinct from atm. oxidation or volatilisation. This is inhibited by antiseptics and occurs in sterile media after inoculation with bacteria from tobacco leaves. Bacterial decomp. of (I) takes place in artificial media, and there is evidence that oxidase, peroxidase, and catalase are produced.  $NH_3$  (but no  $C_5H_5N$ ) is produced, but unlike the  $NH_2Me$  found, it is not derived from (I) but from  $NH_2$ -compounds. A reagent suitable for determining (I) is best prepared by neutralising a mixture of 1 kg. of  $Na_2WO_4 \cdot 2H_2O$  and 117.1 g. of 26.3%  $Na_2SiO_3$  with  $H_2SO_4$ , filtration, extraction of the filtrate with  $Et_2O$  in the presence of 50%  $H_2SO_4$ , and slow evaporation of the  $Et_2O$ . J. G.

**Nornicotine.**—See this vol., 488.

**South American curare.** F. W. FREISE (Pharm. Ztg., 1936, 81, 241—243).—The characteristics and analyses of cork tissues of varying ages from 6 varieties of *Strychnos* are given. The isolation of two alkaloids,  $C_{23}H_{28}O_4N_2$  (similar to or identical with vellosine), and *ecurarine*,  $C_{20}H_{23}ON_2$ , m. p. 135—144°, decomp. 182° (toxic dose for frogs, 0.13 mg. per kg.), is described. E. H. S.

**New alkaloid of ergot.**—See this vol., 489.

**Alkaloids of *Sinomenium* and *Cocculus*.**—See this vol., 491.

**Barley proteins.** I. S. JAITSCHNIKOV and A. D. AVETISJAN (J. Appl. Chem. Russ., 1935, 8, 1439—1443).—The protein-N of barley from different localities of the U.S.S.R. varies from 2.16 to 3.07%; the distribution of the N amongst the albumin, globulin, glutenin, and prolamine fractions is recorded. Varying the order in which the various fractions are extracted (by  $H_2O$ , aq. NaCl, and aq. NaOH) affects the results. R. T.

**Distribution of nucleic acids and proteins in chromosomes.** T. CASPERSON (Naturwiss., 1936, 24, 108).—With the aid of a precipitant containing La, sp. for nucleic acids (I), ultra-violet photomicrographs of chromosomes (II) of extraordinarily fine structure are obtained. Distribution of (I) is identical in both halves of chromosomes. The non-absorbing segments have the properties of proteins. Digestion with proteolytic enzymes dissolves out one of the components, the chromosomes disintegrating into discs and granules of high (I) content. E. A. H. R.

**Highly polymerised compounds.** CIII. Application to biology of investigations on the constitution of highly polymerised compounds. H. STAUDINGER (Zangger-Festschr., 1934, 939—953; Chem. Zentr., 1935, i, 3528; cf. A., 1934, 1336).—The application of earlier work to biological problems, especially protein and rubber chemistry, is discussed. Terminal groups, present in relatively small amount, may be very important factors in determining the chemical properties of fibres. H. N. R.

**Biochemical apparatus.** E. McDONALD (J. Franklin Inst., 1936, 221, 103—138). W. McC.

**Spectrographic analysis of biological materials.** G. H. SCOTT and P. S. WILLIAMS (*Anat. Rec.*, 1935, 64, 107—127).—A method is described. Spectra of normal and pathological tissues are shown.

R. N. C.

**Nephelometric determinations using the photo-electric cell.** J. RENAUDIN (*Bull. Soc. Chim. biol.*, 1936, 18, 301—304).—Nephelometric biological determinations are liable to inherent faults in the apparatus and errors due to the difference in size of suspended particles, and to interfering constituents in the media.

A. L.

**Manometer for comparative study of physiological processes.** B. N. SINGH and P. B. MATHUR (*Biochem. J.*, 1936, 30, 323—325).—Direct reading of the scale suffices when the manometer is used for comparisons. When it is used for quant. determinations the degree of accuracy is  $\pm 1.25\%$ .

W. McC.

**$p_{H}$  determination in biological liquids with the Thompson electrode.** X. THIESSE, M. VERAINE, and A. ZIEGLER (*Bull. Soc. Chim. biol.*, 1936, 18, 203—207).—The glass electrode (A., 1933, 367) may be used.

A. L.

**Method for testing the sense of smell and for the establishment of olfactory values of odorous substances.** C. A. ELSBERG, I. LEVY, and E. D. BREWER (*Science*, 1936, 83, 211—212).

L. S. T.

**Mosaic collodion membranes as analogues of the plasma membrane.** S. C. BROOKS (*J. Exp. Biol.*, 1935, 12, 36—38).—"Anion-impermeable" and "cation-impermeable" membranes arranged in pairs on glass cells did not accumulate or exchange ions except traces of  $Cl^{-}$ .

CH. ABS. (p)

**Histochemical detection of phosphate conglomerates in tissue.** C. HEIDERMANNS and H. WURMBACH (*Z. wiss. Mikrosk.*, 1935, 51, 375—378; *Chem. Zentr.*, 1935, i, 3574).—The material is treated successively with uranyl sulphate,  $HNO_3$ , and  $K_4Fe(CN)_6$ , and observed microscopically.

H. N. R.

**Choice of counterstains.** H. D. MURRAY (*J. Roy. Microscop. Soc.*, 1935, [iii], 55, 233—237).—The absorption spectra of a no. of dyes are examined in relation to their suitability as stains.

H. D.

**Histological applications of tannic acid and ferric chloride.** H. T. NORTHERN (*Stain Tech.*, 1936, 11, 23—24).—The use of tannic acid or  $FeCl_3$  with a cellulose-wall stain (light-green or crystal-violet) and a nuclear lignin stain (safranin) gives clear preps. of plant stems superior to those stained by the usual safranin-crystal-violet and other combinations.

P. G. M.

**Comparative study of dehydration [of animal tissues].** T. T. BAIRD (*Stain Tech.*, 1936, 11, 13—22).—Whatever method of fixation is used, dioxan is the best of known dehydrating agents. The greatest distortion is produced by the  $EtOH-CHCl_3$  method.

P. G. M.

**Counterstains for Davenport reduced silver preparations of peripheral nerves.** J. O. FOLEY (*Stain Tech.*, 1936, 11, 3—8).

P. G. M.

**Lacto-phenol preparations.** W. E. MANEVAL (*Stain Tech.*, 1936, 11, 9—11).—Fungi, algæ, germin-

ating spores, etc. may be stained and mounted in Amann's lacto-phenol containing aniline-blue, cotton-blue, or acid fuchsin either singly or in combination, with or without addition of 20—25%  $AcOH$ . Detailed formulæ are given.

P. G. M.

**Determination of carbamide.**—See this vol., 459.

**Determination of alcohol in putrefied blood and tissues.** M. NICLOUX (*Compt. rend. Soc. Biol.*, 1935, 120, 1301—1303).—The blood or tissue is treated with  $AgNO_3$  and picric acid and distilled; the distillate is treated with  $KOCl$ ,  $Na_2CO_3$ , and  $AgNO_3-NH_3$ , and again distilled, the distillate being acidified and again distilled.  $EtOH$  is determined in the third distillate by any standard method. This process practically eliminates reducing substances, and  $> 99\%$  of  $EtOH$  added to the blood can be recovered.

R. N. C.

**Micro-determination of alcohol in putrefied blood and in corpses.** M. NICLOUX (*Bull. Soc. Chim. biol.*, 1936, 18, 318—351).—The material is first distilled with picric acid and  $AgNO_3$ , then with  $KOCl$  in aq.  $Na_2CO_3$  to remove reducing substances which interfere, the determination being made according to the author's method (A., 1931, 1327).  $EtOH$  administered to white mice previous to killing disappears from the bodies in a regular manner, the rate increasing with rise of temp. Considerable quantities (0.8 g. per kg.) of  $EtOH$  are formed during the putrefaction of corpses, this being accompanied in some cases by 15% of  $BuOH$ .

A. L.

**Micro-determination of alcohol in biological material.** R. N. HARGER (*J. Lab. Clin. Med.*, 1935, 20, 746—751).— $EtOH$  is removed from tissue, blood filtrates, urine, etc. by steam distillation. The distillate is oxidised by  $H_2SO_4-K_2Cr_2O_7$ , excess of the latter being titrated with a solution containing  $FeSO_4$  and Me-orange.

CH. ABS. (p)

**Determination of small amounts of citric acid in biological material.** G. W. PUCHER, C. C. SHERMAN, and H. B. VICKERY (*J. Biol. Chem.*, 1936, 113, 235—245).—Citric acid (I) (0.1—1.0 mg.) was determined in  $CCl_3CO_2H$  extracts by oxidation with  $KMnO_4$  and Br. The pentabromoacetone produced was extracted with light petroleum and treated with aq.  $Na_2S$ ; the colour in the aq. phase was stabilised with  $C_5H_5N$  and its intensity determined spectrophotometrically. Non-volatile ketones and keto-acids interfere if present in large amounts. Small quantities of (I) occur in saliva and erythrocytes.

H. D.

**Isolation from human tissues of easily volatile organic liquids and their identification.** A. O. GETTLER and H. SIEGEL (*Arch. Path.*, 1933, 19, 208—212).— $EtCl$ ,  $C_2H_4Cl_2$ ,  $C_3H_6Cl_2$ ,  $CCl_4$ ,  $CCl_2F_2$ ,  $CHCl_3$ ,  $CS_2$ ,  $C_6H_6$ , and  $Et_2O$  were identified.

CH. ABS. (p)

**Spectrographic determination of phenol in tissue.** G. BARAC and A. LAMBRECHTS (*Bull. Soc. Chim. biol.*, 1936, 18, 239—240).—The ultra-violet spectrum of the  $Et_2O$  extract of the material after defecation with  $CCl_3CO_2H$  is determined. Under these conditions  $PhOH$  gives a max. at 280.7  $m\mu$  with an extinction coeff. of 2400.

A. L.

**Diazo-coupling reaction for detection of o- and p-phenols in histological technique.** M. CLARA

(Z. wiss. Mikrosk., 1935, 51, 316—337; Chem. Zentr., 1935, i, 3574).—Commercial, stabilised diazo-compounds are used.  
H. N. R.

Detection of intravenously injected substances (especially 1-3:4-dihydroxyphenylalanine) inside epithelial cells. Detection of reducing sugar-like substances in the skin of men and animals, by means of silver nitrate. F. SCHAAF and W. BURCKHARDT (Arch. Derm. Syph., 165, 157—173; Chem. Zentr., 1935, ii, 3018).  
H. N. R.

Chemico-toxicological detection of physostigmine. I. MALANDRUCCO (Biochim. Terap. sperim., 18, 242—247; Chem. Zentr., 1935, i, 3020).—A colour reaction is described.  
H. N. R.

Colorimetric determination of morphine and its derivatives. G. RIZZOTTI (Arch. Farm. sperim., 1935, 60, 545—563).—Blood or tissue extracts are deproteinised by  $\text{Na}_2\text{WO}_4\text{--H}_2\text{SO}_4$ , the resulting clear fluid is treated with  $\text{K}_3\text{Fe}(\text{CN})_6$ ,  $\text{Na}_2\text{CO}_3$ , and  $\text{NaCN}$  at  $100^\circ$ , cooled, and  $\text{Fe}_2(\text{SO}_4)_3$  added, and the Prussian-blue developed is compared with that from suitable glucose standards. The method is based on reduction of  $\text{K}_3\text{Fe}(\text{CN})_6$  by the phenolic OH of morphine and certain of its derivatives.  
F. O. H.

Extraction and determination of small amounts of morphine in organs. B. ZANELLA (Arch. Ital. Sci. farmacol., 1, 120—140; Chem. Zentr., 1935, i, 3020).—An improved isolation process is described.  
H. N. R.

Embsden's cholesterol determination. S. MIYAMORI (Nagoya J. Med. Sci., 1935, 8, 135—137).—The material (2 g.) is hydrolysed with 25% aq. KOH at  $100^\circ$ , the  $\text{Et}_2\text{O}$  extract of the product, dried and dissolved in  $\text{CHCl}_3$ , is treated with  $\text{Ac}_2\text{O}$  and  $\text{H}_2\text{SO}_4$ , and the colour measured. The vals. obtained agree with those from the digitonin method.  
NUTR. ABS. (m)

Colorimetric determination of small amounts of cholesterol in blood and other liquids of the organism. M. N. DEL AGUILA (Bol. Soc. quim. Peru, 1935, 1, No. 3, 73—74).—Blood is extracted with  $\text{Et}_2\text{O}$  after addition of  $\text{EtOH}$  (with or without  $\text{NaOH}$ ), and cholesterol is determined by Grigaut's  $\text{Ac}_2\text{O}$  method.  
CH. ABS. (p)

Determination of phytic acid. L. YOUNG (Biochem. J., 1936, 30, 252—257).—Phytic acid (I) is determined by addition of excess of  $\text{FeCl}_3$ , pptn. of Fe phytate at  $100^\circ$  in  $N/6\text{--HCl}$ , and determination of the excess of Fe colorimetrically with CNS'. In faeces extracts (I) is pptd. as before and the ppt. is separated and decomposed with  $\text{NaOH}$ , and after removal of  $\text{Fe}(\text{OH})_3$  the liberated (I) is determined as above.  
H. D.

Detection and determination of copper in organic matter by benzoinoxime. Z. GRUZEWSKA and G. ROUSSEL (Compt. rend. Soc. Biol., 1936, 121, 289—291; cf. this vol., 260).—Cu is accurately determined in rabbit liver by incineration and pptn. from the ash with benzoinoxime in slightly alkaline solution after removal of Fe. The ppt. is sol. in  $\text{CHCl}_3$ , forming a green solution which serves for the detection of Cu.  
R. N. C.

Colorimetric determination of copper in biological material. E. LASAUSSE and L. FROCRAIN (J. Pharm. Chim., 1936, [viii], 23, 77—82; cf. Fleury *et al.*, A., 1929, 784; Delépine, A., 1908, i, 511).—Org. matter is destroyed by ignition at low red heat after addition of  $\text{Mg}(\text{NO}_3)_2$ . The residue, dissolved in  $\text{HCl}$ , is freed from Fe and Ca by addition of aq.  $\text{NH}_3$  and aq.  $(\text{NH}_4)_2\text{CO}_3$ , and Cu is determined colorimetrically by Na dithiocarbamate.  
W. McC.

Modifications of the 2:2'-dipyridyl method for available iron. G. O. KOHLER, C. A. ELVEHJEM, and E. B. HART (J. Biol. Chem., 1936, 113, 49—53; cf. A., 1935, 115).—Chlorophyll and all interfering pigments are pptd. by  $\text{Pb}(\text{OAc})_2$ , and the method can be applied to green vegetables and other pigmented products, as well as to animal tissues. Wherever possible, a fresh and not a dried sample should be used.  
J. N. A.

Non-interference of sodium chloride in the determination of copper and iron in biological material. L. FROCRAIN and E. LASAUSSE (J. Pharm. Chim., 1936, [viii], 23, 84—85).—If  $\text{Mg}(\text{NO}_3)_2$  or  $\text{MgO}$  is present, no loss of Fe or Cu occurs when material is ignited in presence of very large excess of  $\text{NaCl}$ .  
W. McC.

Quantitative spectrographic analysis of biological material. I. Determination of lead in cerebrospinal fluid. J. S. FOSTER, G. O. LANGSTROTH, and D. R. MCRAE (Proc. Roy. Soc., 1935, A, 153, 141—152).—This micro-method is applicable to concns. of  $1 \times 10^{-8}$ — $2 \times 10^{-5}$  g. per c.c. with a precision of  $>15\%$ . It is based on the fact that when the atoms of a sample are excited by a d.-c. spark under suitable conditions, the intensity of a Pb line  $\propto [\text{Pb}]$ , if  $[\text{Pb}]$  is low.  
L. L. B.

Determination of small amounts of lead in biological material. H. CHEFFTEL and M. L. PIGEAUD (Ann. Falsif., 1936, 29, 76—92; cf. A., 1933, 621; B., 1933, 170).—The dithizone (I) method is substituted for the PbS colorimetric method (*loc. cit.*), which is not sufficiently sensitive. Cu etc. are removed by treatment with KCN. Fe is then liable to interfere by producing a brown colour with (I), but this is prevented by avoiding any excess of KCN. Sn does not interfere if present as  $\text{Sn}^{IV}$ .  
E. C. S.

Determination of lead.—See this vol., 443.

Micro-determination of ferrocyanide in muscle and urine. J. G. EDWARDS and W. D. LANGLEY (J. Biol. Chem., 1936, 112, 469—475).— $\text{Fe}(\text{CN})_6^{4-}$  (1—40 mg.) is determined in tissues by hydrolysis with  $\text{H}_2\text{SO}_4$ , absorption of the volatilised HCN in aq.  $\text{NaOH}$ , and titration with  $\text{AgNO}_3$ .  
H. D.

Determination of nitrate in animal tissues. M. WHELAN (J. Lab. Clin. Med., 1935, 20, 755—757).—The ground tissue is acidified ( $\text{H}_2\text{SO}_4$ ) and extracted first with  $\text{Et}_2\text{O}$  and then with hot  $\text{H}_2\text{O}$ .  $\text{Et}_2\text{O}$  is removed from the combined extract, which is then made alkaline, and diluted. An aliquot is treated with  $\text{HgCl}_2$  to remove interfering substances and  $\text{NO}_3^-$  is determined in the clear liquid.  
CH. ABS. (p)

# BRITISH CHEMICAL ABSTRACTS

## A.—PURE CHEMISTRY

MAY, 1936.

### General, Physical, and Inorganic Chemistry.

**Intensity distribution of the continuous spectrum of hydrogen in mixtures with helium and with neon.** N. D. SMITH (Physical Rev., 1936, [ii], 49, 345—350).—The intensity max. was shifted to longer  $\lambda$ . A study of the intensity distribution of the many-line spectrum in the presence of He showed that 20 cm. of He reduced the vibration in the excited states almost to zero, so that the continuous spectrum in presence of He must be due to transitions from the lowest vibrational level of its upper state. The  $\lambda$  distribution of energy in the continuous spectrum for 0.6 mm. H<sub>2</sub> and 21 cm. He, determined by comparison with the radiation emitted from the positive crater of the C arc, showed a max. intensity at about 3200 Å. compared with 2500 Å. under ordinary conditions.

N. M. B.

**Comparison between the continuous molecular spectra of hydrogen and deuterium.** (MILLE.) A. TOURNAIRE and E. VASSY (Compt. rend., 1936, 202, 562—564; cf. this vol., 127).—The distributions of intensity in the spectra have been measured at 1923—4990 Å. and 0.44—3 mm. pressure.

T. G. P.

**Nitrogen atom and the molecule.** L. S. MATHUR and P. K. SEN-GUPTA (Proc. Acad. Sci. Agra and Oudh, 1935, 5, 187—226).—Recent measurements of the various band systems of N<sub>2</sub> are tabulated and discussed critically.

J. W. S.

**Fine structure of the metastable level of nitrogen.** B. STEPANOV (Physikal. Z. Sovietunion, 1935, 8, 352—353).—The N<sub>2</sub> lines 1742.74 and 1745.26 Å. have been resolved and the components found to have the separation 2.13 cm.<sup>-1</sup> Intensity distribution is discussed in relation to the scheme of Compton and Boyce (A., 1929, 365).

R. S.

**Glow discharge through oxygen.** F. D. GREEVES and J. E. McF. JOHNSTON (Phil. Mag., 1936, [vii], 21, 659—686).—A discharge tube fitted with probe tubes has been used for investigating the negative sections of the cold-cathode glow discharge in O<sub>2</sub>, and the range of conditions under which probes can be used without introducing errors determined. Data are given for the electron energy distributions and consens., and for the potential in the discharge.

J. W. S.

**Reversal of the neon lines 744, 736 Å.** T. TAKAMINE and T. SUGA (Sci. Papers Inst. Phys. Chem. Res. Tokyo, 1936, 29, 1—7).—When a strong condensed discharge is passed through a long tube of Ne at several mm. pressure the resonance lines 744 and 736 Å. are considerably broadened and the latter is much the more conspicuously reversed, with a

white gap in the core extending to about 0.3 Å. The contour of this line is quite asymmetric, with its wing extending towards the shorter  $\lambda$  side, and resembles that of the He resonance line 584 Å.

N. M. B.

**Perturbations of Ne I terms.** Y. ISHIDA and T. TAMURA (Sci. Papers Inst. Phys. Chem. Res. Tokyo, 1936, 29, 9—18).—Anomalies in certain sequences can be explained, assuming that the displacement const. of all the series is 780 cm.<sup>-1</sup> or 0, on the basis of Langer's perturbation theory.

N. M. B.

**Photo-electric measurement of the absorption of sodium resonance radiation.** F. FAIRBROTHER and J. L. TUCK (Trans. Faraday Soc., 1936, 32, 624—633; cf. A., 1935, 466).—A photo-electrometric method for measuring the intensity of a beam of Na resonance light with a precision of  $\pm 0.1\%$  is described, and measurements of absorption between 210° and 100° are recorded. The ratio (intensity of transmitted light)/(intensity of incident light) is a nearly linear function of the no. of Na atoms in the path of the beam up to 45% absorption. Beer's law is followed over 25% of the absorption.

F. L. U.

**Effect of a magnetic field on the absorption spectrum of diatomic sulphur molecules.** J. GENARD (Physica, 1936, 3, 125—130; cf. A., 1935, 1045).

N. M. B.

**Molecular spectrum of sulphur vapour.** M. DESIRANT and J. DUCHESNE (Bull. Acad. roy. Belg., 1935, [v], 21, 1062—1068).—Available data are critically reviewed. Investigations towards longer  $\lambda$  in the infra-red showed a new band system, degraded towards the violet, and extending to 7765 Å.; an expression is found for the band heads. The calc. heat of dissociation is  $4.41 \pm 0.02$  e.v.

N. M. B.

**Inter-system combination lines of A III.** J. C. BOYCE (Physical Rev., 1936, [ii], 49, 351).—Data and classifications for 6 of the lines found in the extreme ultra-violet are tabulated, and revised vals. for the singlet terms previously reported are given (cf. A., 1935, 1291).  $\lambda$  of the "forbidden" lines of A III are calc.; one of them agrees closely with a nebular line at  $\lambda$  7135.6.

N. M. B.

**Electron-optical investigations of the glow emission of nickel in caesium vapour.** D. SCHENK (Z. Physik, 1936, 98, 753—758).

A. B. D. C.

**First spark spectrum of copper.** A. G. SHENSTONE (Phil. Trans., 1936, A, 235, 195—243).—The spectrum of the Cu-cathode Schuler tube has been photographed in the range 10,000—600 Å. Tables

of predicted and identified terms, odd and even terms, and full data on  $\lambda$ , intensity, wave-no., and classification for 1350 lines are given. N. M. B.

**Extreme ultra-violet spectra of zinc and cadmium.** L. BLOCH and E. BLOCH (Ann. Physique, 1936, [xi], 5, 325—354).—Using normal and tangent grating spectrographs and an oscillating electrodeless discharge, complete  $\lambda$  and intensities are tabulated for the regions Cd 2322—221, and Zn 2349—227 Å. A fairly complete separation of the Cd II, III, IV, and Zn II, III, IV, spectra has been effected, and a classification of the fundamental multiplets of Cd IV and Zn IV is proposed. N. M. B.

**Intensity distribution of red cadmium lines excited by electron collisions in molecular rays.** R. MINKOWSKI (Z. Physik, 1936, 98, 791).—A printing error is corr. (cf. A., 1935, 1045). A. B. D. C.

**Anomalous dispersion of the first doublets of  $\text{Sr}^+$  and of  $\text{Ba}^+$ .** L. ALLEGRETTI (Atti R. Accad. Lincei, 1935, [vi], 22, 256—258).—The ratio of the anomalous dispersion coeffs.,  $N_1/N_2$ , for the first doublet of the principal series of  $\text{Sr}^+$  and  $\text{Ba}^+$  has the val. 2.07 and 2.16, respectively. O. J. W.

**Absorption of monochromatic light in iodine vapour.** J. HARDING (Phil. Mag., 1935, [vii], 21, 773—778).—The absorption of the 5461, 4358 Å. Hg lines by I vapour  $\propto$  the pressure up to 2.5 cm. The absorption of  $\lambda$  5461 Å. is increased by the presence of 1.8 cm. of He. For  $\lambda$  4358 Å. He has no effect. H. J. E.

**Spectrum of trebly ionised thorium.** R. J. LANG (Canad. J. Res., 1936, 14, A, 43—47).—The spectrum of Th IV has been analysed. The terms  $7P$ ,  $6D$ ,  $7D$ ,  $8D$ ,  $7S$ ,  $8S$ ,  $9S$ ,  $5F$ , and  $5G$  have been found. The ionisation potential of  $\text{Th}^{+++}$  is 29.38 volts. A. J. M.

**Stabilisation of a glow discharge in a homogeneous field in air at atmospheric pressure by means of electrolytically produced films of aluminium oxide.** T. RUMMEL (Naturwiss., 1936, 24, 158).—It was found possible to maintain a stable glow discharge between two plane, parallel Al electrodes covered electrolytically with a film of  $\text{Al}_2\text{O}_3$  (500  $\mu$ ). The stabilising effect of the  $\text{Al}_2\text{O}_3$  is due to the arrangement of pores in the film, which run from the surface to the base, and give a favourable ratio for the length- to cross-section-conductivity. A. J. M.

**Positive ionic current on the glow cathode in a gas discharge.** M. J. DRUYVESTYEN (Physikal. Z. Sovietunion, 1936, 8, 579—581).—The method employed by Gvozdozer (A., 1935, 1293) is criticised. A. J. M.

**Positive ionic current on the glow cathode in a gas discharge.** S. GVOZDOZER (Physikal. Z. Sovietunion, 1936, 8, 582—583).—A reply to Druyvesteyn (preceding abstract). A. J. M.

**Electrical properties of the interrupted arc.** K. GAULRAPP (Ann. Physik, 1936, [v], 25, 705—727).—Oscillograph records of current and voltage as the electrodes are separated have been obtained with a no. of metallic electrodes in air and  $\text{H}_2$  at various pressures. At low pressures the p.d. across a short

arc is independent of the current and length of the arc. Vals. are given for a no. of metals. Metals can be divided into three groups according to the type of trace left on the cathode. A const.-burning a.c. arc is described. L. J. J.

**Fine structure of sudden luminous discharges obtained by discharging a condenser across a gas tube.** M. LAPORTE and (Mlle.) PIERREJEAN (Compt. rend., 1936, 202, 643—645).—Arc and condensed spark spectra of A and Hg have been examined with a rotating mirror. In the cold Hg-A tube, arc and spark spectra of A are emitted; in the hot tube the arc spectrum of Hg is superimposed. L. J. J.

**"Tube" discharges.** R. SEELIGER and K. SOMMERMEYER (Z. Physik, 1936, 98, 733—739).—Constriction of electric discharges observed in electro-negative gases is explained by the electrons normally diffusing outwards, forming negative ions which return towards the discharge. A. B. D. C.

**Nebular red-shift.** R. J. KENNEDY and W. BARKAS (Physical Rev., 1936, [ii], 49, 449—452).—The possible effect of free electrons in a highly ionised gas on the frequency of light traversing it was investigated. Electrons to a density of about  $5 \times 10^{12}$  per c.c. were produced in a series of low-voltage arcs through which passed light of  $\lambda$  5461 Å. No frequency shift was observed with an interferometer in vac. sensitive to 2 parts in  $10^{10}$ . Results indicate that nebular red-shift is not due to interstellar electrons. N. M. B.

**Width of the  $K\alpha_1$  line of molybdenum.** J. WEIGLE (Compt. rend., 1936, 202, 564—566).—The width, measured with a curved mica crystal, is  $0.190 \pm 0.005$  X. T. G. P.

**Monochromatic cobalt  $K\alpha$  radiation (1.787 Å.).** E. I. SOVZ and V. L. CHEIFETZ (Rept. Centr. Inst. Met., 1934, No. 17, 234—236).—The  $K\alpha$  and  $K\beta$  Co radiations were separated by a filter composed of an electrolytic deposit of Fe on Al foil (0.01 mm. thick). CH. ABS. (e)

**Atomic scattering factors of aluminium, nickel, and copper for Cu  $K\alpha$  radiation and their relation to the theory of X-ray dispersion.** G. W. BRINDLEY (Phil. Mag., 1935, [vii], 21, 778—790; cf. this vol., 3).—Data for Ni and Cu were restandardised using Al powder, in place of KCl, as a basis for intensity measurements. H. J. E.

**X-Ray investigation of atomic vibrations in zinc.** G. W. BRINDLEY (Phil. Mag., 1936, [vii], 21, 790—808; cf. this vol., 412).—Reflecting planes making specially small angles with the basal plane of the structure give low scattering factors, whilst planes making angles of approx.  $90^\circ$  give high scattering factors. This anomaly is discussed in relation to Zener's results (this vol., 273). The lattice vibrations of Zn are calc. H. J. E.

**Al  $K\beta$  bands from Al-Cu alloys.** S. YOSHIDA (Sci. Papers Inst. Phys. Chem. Res. Tokyo, 1936, 28, 243—248).—The bands of the X-ray spectrum emitted when targets of pure Al and Al-Cu alloys were bombarded with electrons have been studied. With pure Al (single band) the results agree with the assumption of three free valency electrons. With the alloys the

band separates into two, and the intensity of the second band increases with the % of Cu. A theoretical interpretation is given. R. S. B.

**Intensity ratio  $E_{\alpha\alpha'}/E_{\beta\gamma}$  and yield coefficients  $u_{\alpha\alpha'}$  and  $u_{\beta\gamma}$  for the characteristic  $K$ -radiation from Co (27) to Te (52).** W. GROTHEY (Ann. Physik, 1936, [v], 25, 577—599).—An elaboration of the differential filter method of Küstner (A., 1931, 993) has been employed to determine  $E_{\alpha\alpha'}/E_{\beta\gamma}$ , with an accuracy of  $\pm 6\%$ , for 20 elements from Co to Te and their compounds with light atoms.  $E_{\alpha\alpha'}/E_{\beta\gamma}$  decreases with increasing at. no., and becomes const. after at. no. 47. L. J. J.

**Wave-length determinations for the  $L$  series of elements 29 copper to 26 iron.** F. TYRÉN (Z. Physik, 1936, 98, 768—774). A. B. D. C.

**X-Ray diffraction by a film of counted molecular layers.** C. HOLLEY and S. BERNSTEIN (Physical Rev., 1936, [ii], 49, 403).—Using a film of 301 mol. layers of Ba stearate on glass (cf. Blodgett, A., 1935, 931) and having a grating space of 48.8 Å., the thickness of two mol. layers, the first three orders of the  $L$  series and the  $M$  line of W were photographed. N. M. B.

**Photo-electric effect of aluminium films evaporated in vacuum.** E. GAVIOLA and J. STRONG (Physical Rev., 1936, [ii], 49, 441—443).—Sensitivity curves of Al films deposited by evaporation in vac. were determined. A new threshold val. of 2830 Å. and a selective max. around 2700 Å. were found. N. M. B.

**Photo-effect at thin adsorbed layers of alkali metals.** V. GEI and I. TRUTEN (Physikal. Z. Sovietunion, 1935, 8, 342—351).—The production of multimol. layers of alkali metals on  $\text{SiO}_2$  gel is described. Ohm's law is obeyed by the metal in this state when the e.m.f.  $< 5$  volts, and the photo-effect is normal, with long-wave limits for K 7800 Å. and Cs 9550 Å. R. S.

**Determination of the thermionic work function of nickel by a new method.** R. M. BOWIE (Iowa State Coll. J. Sci., 1934, 9, 131—132).—The electron emission from a cooling Ni sphere charged a condenser, which was discharged through a ballistic galvanometer. CH. ABS. (e)

**Changes of emission potentials of metals near the m.p.** H. KURZKE (Z. Physik, 1936, 98, 684—691).—Theoretical. These changes imply a change in binding energy of "free" electrons near the m.p. A. B. D. C.

**Ionisation probability of  $\text{He}^{++}$ .** W. BLEAKNEY and L. G. SMITH (Physical Rev., 1936, [ii], 49, 402; cf. *ibid.*, 1933, [ii], 43, 378).—The electron energy-ionisation current curve shows a sharp rise at 79 volts attributed to  $\text{He}^{++}$ . At 300 volts the current reaches a max. and is 1.1% of that ascribed to  $\text{He}^+$ , indicating that 0.55% of the ions are doubly charged. N. M. B.

**Effective cross-sections for ion collisions in the absence of resonance.** F. WOLF (Ann. Physik, 1936, [v], 25, 527—544).—Collisions of  $\text{He}^+$  with Ne and A,  $\text{Ne}^+$  with He, and  $\text{H}_2^+$  with He, Ne, and A, at 30—1030 volts, have been studied. With increas-

ing velocity ( $v$ ), the effective cross-section ( $\sigma$ ) falls steeply at low  $v$ , owing to the decrease in the angular scattering; at high  $v$ ,  $\sigma$  increases slowly, owing to transference of charge, which is marked only at high  $v$ , in contrast to the effect for strict resonance.  $\sigma$  is markedly  $<$  the kinetic theory vals. (e.g.,  $< 0.3$  of this val. for  $\text{Ne}^+$ -He collisions). For a given ion, the scattering decreases with increasing mass of the collision partner.  $\sigma$  due to transference of charge corresponds roughly with the resonance principle. L. J. J.

**Individual effects in ion collisions in the absence of resonance ( $\text{H}^+$ ,  $\text{H}_2^+$ ,  $\text{He}^+ \rightarrow \text{He}$ , Ne, A).** F. WOLF (Ann. Physik, 1936, [v], 25, 737—756).—The rôle of charge transference in the collisions  $\text{H}_2^+ \rightarrow \text{A}$ , Ne, He,  $\text{H}^+ \rightarrow \text{A}$ , and  $\text{He}^+ \rightarrow \text{A}$  has been investigated with velocities of 30—1030 volts. For  $\text{H}_2^+ \rightarrow \text{A}$ , as with other collisions, scattering decreases with increasing velocity, whilst ionisation is absent up to 1000 volts. The theoretical form of the charge transference cross-section ( $I$ )-velocity curve is realised only for  $\text{He}^+ \rightarrow \text{A}$  and  $\text{H}^+ \rightarrow \text{A}$ . For  $\text{H}_2^+ \rightarrow \text{A}$ ,  $I$  is large and approx. equal to the effective cross-section, increasing at both high and low velocities; the dissociation  $\text{H}_2^+ \rightarrow \text{H} + \text{H}^+$  is absent. For  $\text{H}_2^+ \rightarrow \text{Ne}$ ,  $I$  is extremely small at all velocities; dissociation is considerable. L. J. J.

**Collision of corpuscular rays with solids.** K. SOMMERMEYER (Ann. Physik, 1936, [v], 25, 481—511).—Mainly theoretical. Sputtering of metals cannot arise from impact of electrons even of high energy, nor by excitation energy of colliding mols. The theory of cathodic sputtering by local heating is developed. Sputtering takes place from locally vaporised collision areas immediately above the crit. temp., and should increase with decreasing  $t_c$ , and be inversely  $\propto$  the thermal conductivity of the cathode. Data for sputtering of KI by  $\text{A}^+$  rays are in agreement; the emission follows Knudsen's cosine law, and the degree of dissociation of the sputtered KI corresponds with a temp. about 3000° abs. The emission of secondary electrons is in agreement with the theory. L. J. J.

**Effect of the electric field on hydrogen atoms in atomic beam experiments.** H. SCHEFFERS and J. STARK (Physikal. Z., 1936, 37, 217—220; cf. A., 1934, 1053).—The deviation of a beam of H atoms in an inhomogeneous electric field gives the val.  $(3 \pm 1) \times 10^{-25}$  e.c. for the polarisability ( $\alpha$ ). A. J. M.

**Calculation in atomic beam experiments in the electric field.** H. SCHEFFERS (Physikal. Z., 1936, 37, 220—221).—Derivations of the formulæ used in computing results of at. beam experiments employing an electric field are given (cf. preceding abstract). A. J. M.

**Scattering of protons by protons.** M. A. TUVE, N. P. HEYDENBURG, and L. R. HAFSTAD (Physical Rev., 1936, [ii], 49, 402).—Data obtained for the angular range 15—45° and 320—980 kv. do not confirm White's results (cf. *ibid.*, 1935, [ii], 47, 573) for the variation of scattering with angle, but are of the order predicted by Mott's formula. N. M. B.

**Positive and neutral rays. III. Ionisation by atomic collision.** A. ROSTAGNI (Nuovo Cim.,

1934, [ii], 11, 621—634; Chem. Zentr., 1935, ii, 15).—The ionisation produced by neutral A atoms in A, or He atoms in He, increases with the velocity. The effective area of A is about 10 times that of He at the same velocity. J. S. A.

**Use of the magnetic field in the formation of ion-electron beams.** A. A. SLUTZKIN (Physikal. Z. Sovietunion, 1935, 8, 255—269).—The influence of the strength and direction of the magnetic field on the ion-electron beam generated in a magnetron system has been studied. R. S.

**Anomalous secondary electron emission.** L. MALTER (Physical Rev., 1936, [ii], 49, 478).—Al oxidised electrolytically in a bath of borax and  $\text{H}_3\text{BO}_3$  assumes a resistive surface film having a high emission coeff. for secondary electrons. Electron bombardment results in the establishment of an intense potential gradient through the resistive oxide film, and this gradient gives rise to anomalous secondary electron emission. N. M. B.

**Absolute values of the electron mobility in hydrogen.** N. E. BRADBURY and R. A. NIELSEN (Physical Rev., 1936, [ii], 49, 388—393).—A new electrical shutter method for measuring electron mobilities in gases is described. Results are compared with those of the Compton mobility equation. N. M. B.

**Scattering of high-speed electrons.** A. MATVEEV and F. VERGUNAS (Physikal. Z. Sovietunion, 1935, 8, 430—442).—The angular distribution of electrons of 200—240 kv. energy after nuclear scattering in Al, Pb, and Ag is investigated. The experimental results are compared with the theories of nuclear scattering and a difference is found in the magnitude of scattering with light and heavy nuclei. W. R. A.

**Motion of electrons in crossed electric and magnetic fields with space-charge.** L. TONKS (Physikal. Z. Sovietunion, 1935, 8, 572—578).—The conclusions of Braude (A., 1935, 1294) concerning the absence of a magnetic cut-off in the presence of a space-charge are criticised. A. J. M.

**"Cut-off" in the plane magnetron with space-charge.** S. J. BRAUDE (Physikal. Z. Sovietunion, 1935, 8, 584—586).—A reply to Tonks (preceding abstract). A. J. M.

**At. wt. of carbon.** G. P. BAXTER and A. H. HALE (J. Amer. Chem. Soc., 1936, 58, 510—515).—Gravimetric data obtained by combustion of pyrene, chrysene,  $\text{C}_6\text{H}_3\text{Ph}_3$ , and anthracene in  $\text{O}_2$  give the val. 12.009. E. S. H.

**Masses of light atoms.** M. L. OLIPHANT (Nature, 1936, 137, 396—397).—The masses of elements up to and including F are recalculated from transformation data and Aston's new data (this vol., 400). The high val. found for the mass of the neutron (1.0091) raises the question of its stability. Plotting the departure of the mass of an at. species from a whole no. in terms of  $^{16}\text{O}=16.0000$  against the mass no. gives a smooth curve showing repeated oscillations. Deductions concerning the stability of at. species are made, and the probable existence of He of mass 5.0125 is predicted. L. S. T.

**At. wt. of radiogenic lead.** F. HECHT and E. KROUPA (Z. anorg. Chem., 1936, 226, 248—256).—At. wts. of Pb determined by nephelometric titration with  $\text{AgNO}_3$  of  $\text{PbCl}_2$  obtained from various minerals are as follows: pitchblende from Great Bear Lake, 206.080; uraninite from Wilberforce, 206.183; pitchblende from Katanga, 206.044; ordinary galena, 207.216. The HCl-insol. part of the Katanga pitchblende was used. F. L. U.

**At. wt. of uranium.** O. HÖNIGSCHMID and F. WITTNER (Z. anorg. Chem., 1936, 226, 289—309).—The prep. and purification of  $\text{UCl}_4$  and  $\text{UBr}_4$  from four minerals of different origin and geological age are described. The mean at. wt. of U, determined argentometrically, from 18 analyses of  $\text{UCl}_4$ , is 238.073, and from 20 analyses of  $\text{UBr}_4$ , 238.076. The final val. is given as  $238.07 \pm 0.02$ . The differences in the vals. given by the four minerals are within the experimental error, and afford no support for the suggestion that minerals of different geological age contain metal of varying isotopic composition. F. L. U.

**Small chemical separation of the chlorine isotopes.** R. S. BRADLEY (Nature, 1936, 137, 403—404).—The slight increase in  $d$  observed for  $\text{CCl}_4$  after some of it has been decomposed by refluxing with Na amalgam is attributed to a small separation of the Cl isotopes, the light isotope reacting preferentially. No isotopic separation occurs on repeated distillation of  $\text{CCl}_4$  alone (cf. A., 1929, 484). L. S. T.

**Isotope separation for thallium by valency exchange?** J. ZIRKLER (Z. Physik, 1936, 98, 790).—Previous results (this vol., 282) suggest that valency exchange gives isotopic separation. A. B. D. C.

**Periodic system of the elements and its gaps.** I. NODDACK (Uspechi Chim., 1935, 4, 11—21).—Negative results were obtained in a search for elements of at. no. 61 and 87 in minerals which might contain them. CH. Abs. (e)

**Scattering of fast  $\beta$ -rays.** D. SKOBEŁTZYN and E. STEPANOVA (Nature, 1936, 137, 456).—The anomalous scattering of fast  $\beta$ -rays observed in  $\text{N}_2$  is probably due to an intranuclear effect. L. S. T.

**$\beta$ -Rays of high energy.** J. A. GRAY and W. J. HENDERSON (Physical Rev., 1936, [ii], 49, 477).—Intensity measurements show that there is no indication of the emission of  $\beta$ -rays of high energy beyond the main spectrum of Ra-E. N. M. B.

**$\beta$ -Activity induced by  $\gamma$ -rays.** W. RARITA (Physical Rev., 1936, [ii], 49, 475).—A nucleus which is not naturally  $\beta$ -active may be stimulated to emit a  $\beta^-$  or  $\beta^+$  particle under the influence of a  $\gamma$ -ray. The mechanism and emission cross-section are examined. N. M. B.

**Deviation of  $\beta$ -rays by nitrogen nuclei.** M. LECOIN (Compt. rend., 1936, 202, 839—840).—The ratio of the loss of energy to the initial energy of a  $\beta$ -ray in  $\text{N}_2$ , when deviated by  $> 10^\circ$ , has been determined for a no. of rays, and the effective sections of the nucleus for shocks corresponding with different energy losses have been calc. These are considerably  $>$  predicted by theory. M. S. B.

**Influence of pressure and temperature on the recombination coefficient and ionisation by  $\gamma$ -rays in air and carbon dioxide.** W. MÄCHLER (Physikal. Z., 1936, 37, 211—213).—The recombination coeff.  $\alpha$  was determined for  $\text{CO}_2$  up to 25 atm., and from 18° to 52°. Results agree closely with those of Langevin (Ann. Chim. Phys., 1903, 28, 433).  $\alpha$  for air decreases with rising temp., but for  $\text{CO}_2$  there is a very small increase. A. J. M.

**$\gamma$ -Rays of radium-*E*.** J. A. GRAY and J. F. HINDS (Physical Rev., 1936, [ii], 49, 477).—Absorption and intensity measurements show that the  $\gamma$ -rays of Ra-*E* are really X-rays produced by  $\beta$ -rays in escaping from the atoms in which they are produced. N. M. B.

**Scattered and secondary radiation of hard  $\gamma$ -rays.** W. BOTHE and W. GENTNER (Naturwiss., 1936, 24, 171—172; cf. A., 1934, 342, 713).—The dependence of the intensity of secondary radiation of hard  $\gamma$ -rays on the thickness of the radiator has been investigated for very thin layers of Pb (0.06 mm.) and Al (0.2 mm.). The thinness of the layers avoids the complications due to the multiple Compton scattering. A. J. M.

**Excitation of  $\gamma$ -rays by fast neutrons.** S. KIKUCHI, H. AOKI, and K. HUSIMI (Nature, 1936, 137, 398).—The relation between at. no. and the capture cross-sections for fast neutrons in various elements is tabulated. Discontinuities which may be connected with the internal structure of the nuclei of light elements are pointed out. L. S. T.

**Disintegration of the deuteron by  $\gamma$ -rays.** H. HALL (Physical Rev., 1936, [ii], 49, 401—402).—An upper limit to the range of the proton-neutron interaction is discussed in relation to the val. of the cross-section for photo-electric disintegration of a deuteron by  $\gamma$ -rays (cf. Bethe, A., 1935, 279). N. M. B.

**Position of the lowest energy term of the deuteron.** V. RAJEVSKI (Physikal. Z. Sovietunion, 1935, 8, 511—515).—The position of the 1's term of the deuteron can be obtained from the experimental val. of the scattering cross-section of slow neutrons in  $\text{H}_2$ . The term separation  ${}^3E-{}^1E$  thus derived is  $1.7 \times 10^6$  e.v. Consideration of the scattering of rapid neutrons in  $\text{H}_2$  leads to a val. for the radius of the deuteron rather  $> 3 \times 10^{-13}$  cm. A. J. M.

**Relative positions of the resonance levels for the capture of neutrons by silver and iodine.** P. PREISWERK and H. VON HALBAN, jun. (Compt. rend., 1936, 202, 840—842).—The energy of the resonance level of I is shown to be  $>$  that of the isotopes of Ag which form radio-Ag (period 22 sec.) by capturing a neutron. M. S. B.

**Neutron capture and the structure of the atomic nucleus.** N. BOHR (Naturwiss., 1936, 24, 241—245).—A lecture.

**Determination of the selective absorption regions of slow neutrons.** D. F. WEEKES, M. S. LIVINGSTON, and H. A. BETHE (Physical Rev., 1936, [ii], 49, 471—473).—A method is described for measuring energies of neutrons outside the thermal energy range (cf. Fink, this vol., 264), but in the

range deduced from the Wigner-Breit resonance theory of selective absorption. N. M. B.

**Absorption of neutrons detected by boron and lithium.** D. P. MITCHELL (Physical Rev., 1936, [ii], 49, 453—458).—Data are given for the neutron-nucleus collision cross-sections of H,  $\text{HgO}$ , Sm, Al, B, C, Fe, and Li for neutrons that are detectable by the B and by the Li neutron capture reaction and that are strongly absorbed by Cd. The vals. for the three first named differ considerably by the two detectors, and for the others are the same within 10%. Variation of the absorption coeff. of Cd, B, and Li with intensity, the effect of filtering through Ag, Cd, B, and Li, and through paraffin at 293° and 90° abs., and the velocity distribution were investigated. N. M. B.

**Absorption of neutrons in water, paraffin, and charcoal.** L. ARZIMOVITSCH, I. KURTSCHATOV, G. LATISCHEV, and V. CHROMOV (Physikal. Z. Sovietunion, 1935, 8, 472—486).—The  $\gamma$ -radiation, which results from the passage of neutrons through substances, is investigated and its intensity measured. The absorption coeffs. of neutrons for these substances are given and the effective cross-sections of neutrons compared with at. nuclei are ascertained. W. R. A.

**Scattering of slow neutrons.** A. C. G. MITCHELL, E. J. MURPHY, and L. M. LANGER (Physical Rev., 1936, [ii], 49, 400).—Investigations previously reported (cf. A., 1935, 1441) are extended to a determination of the % scattering curves and data for C, Mg, Al, S, Cr, Mn, Ni, Zn, Ag, Cd, and Bi. The respective relative cross-sections for scattering are 3.2, 2.8, 0.9, 0.8, 1.3, 2.0, 17.0, 3.4, 5.9, 1.2, and 9.5. Results are compared with those by the "absorption" method (cf. Dunning, *ibid.*, 1186). N. M. B.

**Selective scattering of slow neutrons.** A. C. G. MITCHELL, E. J. MURPHY, and M. D. WILTAKER (Physical Rev., 1936, [ii], 49, 401; cf. preceding abstract).—Using Ag, Rh, and In detectors, data are given for % scattering by Fe, Ni, Pb, Cu, Sn, Al, Bi, C, and Zn. Vals. differ widely for a given element with different detectors, and possible explanations are discussed. N. M. B.

**General theory of fluctuations in radioactive disintegration.** A. RUARK and L. DEVOL (Physical Rev., 1936, [ii], 49, 355—367; cf. this vol., 5).—Mathematical. N. M. B.

**Coincidence investigations on nuclear processes.** W. BOTHE and H. J. VON BAeyer (Nachr. Ges. Wiss. Göttingen, 1935, [ii], 1, 195—197; Chem. Zentr., 1935, ii, 646).—A concentric arrangement of eight counters around a central source and counter, with interposed absorbing screens, gave the expected coincidences between  $\beta$ - and  $\gamma$ -radiation from Rn. With artificially radioactive B, no coincidences between proton and  $\gamma$ -ray emission were found, in support of the views of Bothe and Becker (A., 1931, 1208). J. S. A.

**Capacity of the elements for disintegration.** T. SEXL (Physikal. Z., 1936, 37, 221—222).—A

formula used by Stetter (this vol., 265) is not applicable for elements with at. no. in the region of 5.

A. J. M.  
**Slowing down of neutrons.** S. GOUDSMIT (Physical Rev., 1936, [ii], 49, 406; cf. Wick, this vol., 264).—Mathematical.  
 N. M. B.

**Method for investigating artificially radioactive elements with very short periods.** K. S. KNOL and J. VELDKAMP (Physica, 1936, 3, 145—146).—A wheel, coated at the circumference with the element under investigation, rotates along the bombarding neutron source and is used with one or more counters. For  $\text{Li}_2\text{CO}_3$  bombarded with slow neutrons the resulting half-period is 0.7 sec., ascribed to the active isotope  ${}^3\text{Li}^8$ .  
 N. M. B.

**Efficiencies of production and the half-lives of radio-carbon and radio-nitrogen.** S. K. ALLISON (Proc. Camb. Phil. Soc., 1936, 32, 179—182).—The half-life of the activity produced by bombardment of a thick, solid target of  $\text{B}_2\text{O}_3$  by deuterons varies with time elapsing after the bombardment, the limits being 17.5 and 21.5 min. The low vals. are obtained immediately after bombardment, and are due to radio-N obtained from deuteron bombardment of C present as an impurity in the  $\text{B}_2\text{O}_3$ . Only radio-C is produced by the deuteron bombardment of  $\text{B}_2\text{O}_3$ , the mean half-life of radio-C removed from  $\text{B}_2\text{O}_3$  being  $21.0 \pm 0.6$  min. The half-life of radio-N obtained by bombardment of graphite by protons and deuterons, respectively, is the same ( $10.3 \pm 0.3$  min.). The efficiencies of production of radio-C and radio-N by various methods are compared.  
 A. J. M.

**Radiations emitted from artificially produced radioactive substances. I. Upper limits and shapes of the  $\beta$ -ray spectra from several elements.** F. N. D. KURIE, J. R. RICHARDSON, and H. C. PAXTON (Physical Rev., 1936, [ii], 49, 368—381).—The  $\beta$ -ray spectra of  $\text{N}^{13}$ ,  $\text{F}^{17}$ ,  $\text{Na}^{24}$ ,  $\text{Si}^{31}$ ,  $\text{P}^{32}$ ,  $\text{Cl}^{41}$ , and  $\text{K}^{42}$ , investigated by measuring the curvature of the tracks due to the  $\beta$ -rays in a cloud-chamber traversed by a known magnetic field, give results in good agreement with theory (cf. Konopinski, A., 1935, 1048), which, however, gives an upper limit  $>$  is found from the data. The upper limit of  $\text{N}^{13}$  is 1.5 mv.  
 N. M. B.

**Induced radioactivity of mercury.** E. B. ANDERSEN (Nature, 1936, 137, 457).—Bombardment of  $\text{HgO}$  by neutrons from a Rn-Be source yields an active product, probably  ${}^{80}\text{Hg}^{205}$ , decaying with a period of  $40 \pm 5$  hr.  $\text{CCl}_4$ , irradiated with neutrons, yields an active isotope of S decaying with a period  $> 2$  months. Irradiation of  $\text{Bi}_2\text{O}_3$  gives no measurable activity.  
 L. S. T.

**New transformation processes in the irradiation of uranium with neutrons.** L. MEITNER and O. HAHN (Naturwiss., 1936, 24, 158—159).—In addition to the elements of half-life 13 min., 100 min., and 3 days, respectively, previously discovered (A., 1935, 278, 1050), an element of half-life 12 hr. has been obtained by irradiation of U with neutrons. It is a higher homologue of the Pt group (eka-Os $^{237}$ ). For the investigation of the

processes by which these and other transformations with U occur, the activity produced in U by bombardment with rapid and with slow (through paraffin) neutrons, respectively, has been examined. Three concurrent processes take place. (1)  $\text{U}^{238} + n \rightarrow \text{Th}^{235} + \alpha$ ;  $\text{Th}^{235} \xrightarrow{\beta} \text{Pa}^{235} \xrightarrow{\beta} \text{U}^{235} \xrightarrow{\beta} \text{eka-Re}^{235} \rightarrow (?)$ . This occurs only when slow neutrons are used. (2)  $\text{U}^{238} + n \rightarrow \text{U}^{237} + 2n_1$ ;  $\text{U}^{237} \xrightarrow{\beta} \text{eka-Re}^{237} \xrightarrow{\beta} \text{eka-Os}^{237} \xrightarrow{\beta} \text{eka-Ir}^{237} (?)$ . This process is confirmed by the fact that the 13-min. element (eka-Re $^{237}$ ;  $Z=93$ ) is formed in smaller amount when the bombarding neutrons are slower. The process is brought about by rapid neutrons.  $\text{U}^{237}$  has half-life 40 sec.  $\text{U}^{238}$ , an  $\alpha$ -radiator of long life, and  $\text{U}^{237}$ , a  $\beta$ -radiator of short life, are analogous to  $\text{Th}^{232}$  and U-Y. (3)  $\text{U}^{238} + n_1 \rightarrow \text{U}^{239}$ ;  $\text{U}^{239} \xrightarrow{\beta} \text{eka-Re}^{239} \xrightarrow{\beta} \text{eka-Os}^{239} \xrightarrow{\beta} \text{eka-Ir}^{239}$ . This process occurs for bombardment with slow neutrons. Half-lives are eka-Re $^{239}$  2.2 min., eka-Os $^{239}$  59 min., eka-Ir $^{239}$  3 days.  
 A. J. M.

**Absorption of penetrating corpuscular radiation under different zeniths.** G. BERNARDINI and D. BOCCIARELLI (Ric. sci. Prog. tec., 1935, 6, 33—39; Chem. Zentr., 1935, ii, 12).—At three different inclinations, a superimposed soft and a hard radiation were detected, which were similarly distributed spatially.  
 J. S. A.

**Measurement of cosmic-ray showers by means of Geiger-Müller counters.** C. G. MONTGOMERY and D. D. MONTGOMERY (J. Franklin Inst., 1936, 221, 59—64).—Mathematical. A statistical basis for the formulation of experimental data is deduced.  
 L. J. J.

**Can protons represent the primary cosmic rays at sea level?** W. F. G. SWANN (Physical Rev., 1936, [ii], 49, 478; cf. A., 1935, 1442).—Difficulties in this view are discussed. The protons probably function through the production of secondary rays which are then observed by the counters.  
 N. M. B.

**Variations of properties of cosmic shower radiations with altitude.** J. C. STEARNS and D. K. FROMAN (Physical Rev., 1936, [ii], 49, 473—474, 591).—Curves for rates of shower detection in the determination of optimum thickness of Pb for shower production at altitudes of 120, 5300, 10,800, and 14,200 feet show no variation in shape or optimum Pb thickness with altitude, but the shape and max. vary with the method used. Curves for absorption measurements with Pb thickness are given.  
 N. M. B.

**Cloud chamber photographs of counter-selected cosmic-ray showers.** E. C. STEVENSON and J. C. STREET (Physical Rev., 1936, [ii], 49, 425—428).—Cosmic-ray showers from a Pb plate 1.3 cm. thick in a large cloud chamber controlled by three counters are described and discussed.  
 N. M. B.

**Direct photographic tracks of atomic cosmic-ray corpuscles.** T. R. WILKINS and H. ST. HELENS (Physical Rev., 1936, [ii], 49, 403).—A photograph obtained on a stratosphere flight shows a track interpreted as due to an  $\alpha$ -particle; at a point on the

path is the track of an ejected particle which is probably a proton. N. M. B.

Periods of natural and artificial radioactive bodies, the existence of shells, and the classification of atomic nuclei. B. KEVAL and (MLLE.) A. RIEDERBERGER (Compt. rend., 1936, 202, 566—567).—The existence of closed shells of protons suggests the possibility of a natural classification of at. nuclei. T. G. P.

Theory of the atomic nucleus. P. JORDAN (Naturwiss., 1936, 24, 209—216).—A review.

Structure of the electron and positron. U. KAKINUMA (Sci. Papers Inst. Phys. Chem. Res. Tokyo, 1936, 28, 249—270).—Theoretical. A wave equation for the electron similar to Schrödinger's is derived on the assumption of finite and continuous energy density. The radius of the electron is calc. to be approx.  $10^{-30}$  cm. The nature of the electron and positron and their bearing on cosmology are discussed. R. S. B.

Interaction between protons and neutrons. G. WATAGHIN (Compt. rend., 1936, 202, 833—835).—Theoretical. M. S. B.

Electron-neutron interaction. E. U. CONDON (Physical Rev., 1936, [ii], 49, 459—461).—Mathematical. N. M. B.

Polarisation effects in the positron theory. W. PAULI and M. E. ROSE (Physical Rev., 1936, [ii], 49, 462—465).—Mathematical. N. M. B.

Light quanta and neutrinos. P. JORDAN (Z. Physik, 1936, 98, 759—767).—Postulates two neutrinos corresponding with positive and negative electrons. A. B. D. C.

Consequences of Dirac's positron theory. W. HEISENBERG and H. EULER (Z. Physik, 1936, 98, 714—732).—Theoretical. Necessary modifications of Maxwell's equations are deduced. A. B. D. C.

Effects of exchange forces on the excitation function of  $\text{Li}^7$  under proton bombardment. M. OSTROFSKY, W. E. BLEICK, and G. BREIT (Physical Rev., 1936, [ii], 49, 352—354).—Van Vleck's recently reported effective potential due to Majorana exchange forces varies with proton or neutron velocity (cf. A., 1935, 1296). The effect of this variation on the shape of the excitation curve of Li under proton bombardment is negligible, but the position of stationary proton levels is largely affected. Agreement of calculations with the mass defect of  $\text{Be}^8$  is improved by using the exchange potential. N. M. B.

Depth distribution of energy absorbed from cathode rays by aluminium. K. GENTNER and W. ROLLWAGEN (Physikal. Z., 1936, 37, 214—215).—The experimental distribution curve agrees with theory. A. J. M.

Lower limit of the helium ground state calculated by Ritzsch's method. W. ROMBERG (Physikal. Z. Sovietunion, 1935, 8, 516—527).—Calculations of the lower limit of the ground state for He by the methods of Hylleraas (A., 1928, 698; 1929, 616), Ritzsch (Kellner, A., 1927, 912), and Weinstein (A., 1932, 787) are discussed. The method of Ritzsch gives good results. A. J. M.

Analytical wave-functions for beryllium-like atoms. V. FOCK and (Miss) M. PETRASHEN (Physikal. Z. Sovietunion, 1935, 8, 359—368). Analytical wave-functions of H-like type are constructed for atoms with four electrons and an arbitrary nuclear charge. Energy vals. are compared with those calc. by the method of self-consistent field with and without exchange, and with observed vals. for Be,  $\text{B}^{+1}$ ,  $\text{C}^{+2}$ ,  $\text{N}^{+3}$ ,  $\text{O}^{+4}$ . A semi-empirical formula for the energy in terms of the nuclear charge is deduced. W. R. A.

Deuteron theory. D. BLOCHINZEV (Physikal. Z. Sovietunion, 1935, 8, 270—274).—The theory of the deuteron is discussed from the relativistic viewpoint. R. S.

Atomic dimensions. M. PIERUCCI (Nuovo Cim., 1934, [ii], 11, 690—700; Chem. Zentr., 1935, ii, 322; cf. A., 1921, ii, 583).—At. radii are exact multiples of 0.0398 Å. This rule is consistent with wave mechanics. H. J. E.

Definition of electromagnetic field in terms of potentials; magnetic moment of the electron. A. PROCA (Compt. rend., 1936, 202, 641—643).—A complete description of an electromagnetic field must take into account the magnetic as well as the electric potential. The existence of the magnetic moment of the electron is implicit in the Maxwell-Lorentz equations. L. J. J.

Proper mass of the photon and the electromagnetic tensor. J. GÉHÉNIAU (Compt. rend., 1936, 202, 559—560).—Mathematical. T. G. P.

Franck-Condon principle. A. S. COOLIDGE, H. M. JAMES, and R. D. PRESENT (J. Chem. Physics, 1936, 4, 193—211).—Theoretical. M. S. B.

Interaction of "spinor"-particles. P. JORDAN (Z. Physik, 1936, 98, 709—713).—Theoretical. A. B. D. C.

Photon counters for visible and ultra-violet. Z. OLLANO (Nuovo Cim., 1934, [ii], 11, 603—620; Chem. Zentr., 1935, ii, 18).—The sp. sensitivity of a variety of photo-electrically active surfaces has been determined over the spectral range indicated. J. S. A.

Application of a simplified model of the Jamin polarisation interferometer to the study of absorption. P. BARCHWITZ (Compt. rend., 1936, 202, 300—301). H. J. E.

Absorption spectrum of solid oxygen. II. A. PRICHOTKO and M. RUHEMANN (Physikal. Z. Sovietunion, 1935, 8, 294—299; cf. A., 1935, 1291).—Five band groups similar to the first two series in the visible have been observed between 4000 and 3000 Å. with layers of  $\alpha\text{-O}$  of different thickness. Preliminary results for the region below 3000 Å. are given. R. S.

Continuous absorption spectra of diatomic molecules. H. TRIVEDI (Proc. Acad. Sci. Agra and Oudh, 1935, 5, 171—186).—Mathematical. J. W. S.

Far ultra-violet absorption spectra and ionisation potentials of  $\text{H}_2\text{O}$  and  $\text{H}_2\text{S}$ . W. C. PRICE (J. Chem. Physics, 1936, 4, 147—153).—The absorption spectra of  $\text{H}_2\text{O}$  and  $\text{H}_2\text{S}$  for  $\lambda\lambda < 1600$  Å. give

Rydberg series of which the limits indicate  $12.56 \pm 0.02$  and  $10.42 \pm 0.01$  volts, respectively, as the ionisation potentials of the two mols. The analysis agrees with Mulliken's prediction that the bands should be due to the excitation and removal of a non-bonding electron localised near O or S.

M. S. B.

Spin coupling in the  $^3\Sigma$ -state of phosphorus deuteride. R. W. B. PEARSE and M. ISHAQUE (Nature, 1936, 137, 457).

L. S. T.

Ultra-violet absorption in hydrogen fluoride. H. J. PLUMLEY (Physical Rev., 1936, [ii], 49, 405; cf. *ibid.*, 1935, [ii], 48, 105).—A correction.

N. M. B.

Optical properties of lithium fluoride in the extreme ultra-violet. E. G. SCHNEIDER (Physical Rev., 1936, [ii], 49, 341—345).—Variations similar to those for natural fluorite were found for the absorption coeff. of 50 laboratory-produced crystals of LiF in the extreme ultra-violet. Light lost at the surface from a transmitted beam and effects of surface cleaning and polishing were investigated. The refractive index (about 1.65 at 1200 Å.) was extended into the Schumann region by a modified min. deviation method.

N. M. B.

Influence of fluorides on the spectral absorption of coloured iron complexes. W. WEYL and H. RUDOW (Z. anorg. Chem., 1936, 226, 341—349).—Addition of F' to Fe(CNS)<sub>3</sub>, Fe salicylate, sulphosalicylate, or acetylacetonate leads to formation of the colourless FeF<sub>6</sub>'''', and thereby diminishes the intensity of coloration. Simultaneously the absorption bands are broadened and their max. shifted towards shorter  $\lambda$ , owing to loose addition of F'. The effect of added F' diminishes with rising temp., whilst simultaneous addition of H<sub>3</sub>BO<sub>3</sub>, which yields a complex with F', shifts the bands towards longer  $\lambda$ .

J. W. S.

Photochemistry of nitrites, nitrates, and nitro-compounds. H. W. THOMPSON and C. H. PURKIS (Trans. Faraday Soc., 1936, 32, 674—680).—Absorption spectra of Me and Et nitrites, MeNO<sub>3</sub>, EtNO<sub>3</sub>, nitro-methane and -ethane have been measured. The results are discussed. V.p. of the three Me compounds have been determined over a wide range and are expressed in formulæ.

F. L. U.

Intensities in the bands of the violet cyanogen system. N. R. TAWDE (Proc. Indian Acad. Sci., 1936, 3, A, 140—147).—Vibrational intensities in the  $2\Sigma \rightarrow 3\Sigma$  system of CN, emitted by a C arc in air, are estimated by the method of heterochromatic spectral photometry. The experimental distribution of intensities is compared with that derived by the application of the Franck-Condon principle of max. transitions from the potential energy functions of Morse and of Rydberg.

O. D. S.

Absorption spectra of chromium, molybdenum, and tungsten hexacarbonyls in vapour and dissolved states. G. MILAZZO and G. SCHEIBE (Z. physikal. Chem., 1936, B, 31, 431—438).—The absorption curves in the vapour state in the visible and down to about 1600 Å. consist of three continuous absorption regions at about 3800, 2800, and 2300 Å.,

respectively. It is inferred that light absorption in all three regions leads to dissociation; to what products of dissociation they are to be attributed is uncertain. The absorption curves of the EtOH and hexane solutions are practically the same as those of the vapours.

R. C.

Werner complexes. Absorption of hexacoordinated cobalt and chromium derivatives in aqueous solution. J. P. MATHIEU (Bull. Soc. chim., 1936, [v], 3, 463—475).—The absorption spectra of 24 complexes in aq. solution have been determined in the visible region. A wide absorption band is observed in each spectrum at a position varying with the chemical lability of the co-ordinated groups. In certain cases the wide band splits into two bands.

E. S. H.

[Optical absorption of substituted benzenes. VI.] H. CONRAD-BILLROTH (Z. physikal. Chem., 1936, B, 31, 475—476).—Corrections and comments on Steurer's paper (this vol., 8).

R. C.

Influence of physical state on absorption and fluorescence spectra of organic substances. P. K. SESHAN (Trans. Faraday Soc., 1936, 32, 689—694).—The positions of some absorption bands of fluorene, naphthacene, and perylene have been measured in the vapour, liquid, and solid state, and in liquid and solid solution. Corresponding with the change vapour  $\rightarrow$  solution  $\rightarrow$  liquid  $\rightarrow$  solid there is a progressive broadening of the absorption bands and a displacement of the whole band system towards the red. For solutions in different solvents, the shift towards the red is the greater, the higher is the refractive index of the solvent. For a given solvent the position of the bands is nearly independent of concn. when the solutions are dil. Similar results have been obtained for the fluorescence bands.

F. L. U.

Alterations in the spectra of solutions of diacenaphthylidene. I. Influence of solvent on fluorescence and absorption spectra. II. Influence of temperature on the fluorescence spectrum. B. TWAROWSKA (Acta phys. polon., 1933, 2, 267—272, 273—281; Chem. Zentr., 1935, ii, 346—347).—I. The fluorescence max. move towards the violet as the  $d$  of the solvent decreases. In xylene and isoamyl alcohol the fluorescence bands and, less markedly, the absorption bands tend to come together.

II. At lower temp. the fluorescence bands become smaller and sharper, and tend to split up into groups; the effect varies somewhat from solvent to solvent.

H. N. R.

Absorption spectra of some aromatic compounds. I. Hydrocarbons. II. Quinones and quinols. P. K. SESHAN (Proc. Indian Acad. Sci., 1936, 3, A, 148—171, 172—187).—I. An investigation of the variations produced in absorption spectra of aromatic compounds by the progressive addition of benzene rings to the mol. Absorption spectra have been determined from 7000 to 2300 Å. of C<sub>10</sub>H<sub>8</sub>, anthracene, naphthacene, phenanthrene, 1:2-benzphenanthrene, pyrene, and fluorene in solid and vapour states and in EtOH, of 1:2:5:6-dibenzanthracene in the solid state and EtOH solution, of

perylene, acenaphthene, fluorene,  $\text{CH}_2\text{Ph}_2$ , and  $\text{C}_2\text{H}_4\text{Ph}_2$  in the vapour state and in EtOH, and of  $\text{Ph}_2$ ,  $\text{C}_6\text{H}_4\text{Ph}_2$ ,  $\text{CHPh}_3$ ,  $s\text{-C}_6\text{H}_3\text{Ph}_3$ ,  $s\text{-C}_6\text{H}_2\text{Me}_4$ , and  $\text{C}_6\text{Me}_6$  in the vapour state. Characteristic vibrational and electronic frequencies are calc. The relation between the structure of the mol. and the nature of the absorption spectrum is discussed.

II. Absorption spectra have been determined between 7000 and 2200 Å. of *p*-benzoquinone (I) and quinol (II) in solid and vapour states and in EtOH solution, of 1:4-naphthoquinone (III), anthraquinone (IV), phenanthraquinone (V), 2-hydroxyanthraquinone in the vapour state and EtOH solution, and of naphthazarin, phloroglucinol, and quinhydrone (VI) in the vapour state. The spectra of (I) and (II) show rotational fine structure. Vibrational and electronic frequencies are calc. for (III), (IV), and (V). Vibrational fine structure is absent in the spectra of the quinols. The absorption of (VI), at  $t > 100^\circ$ , is a superposition of those of (I) and (II) which are probably present as dissociation products.

O. D. S.

Absorption spectra of pyocyanine, prodigiosine, and violaceine. O. EHRSIMANN and W. NOETHLING (Biochem. Z., 1936, 284, 376—382).—Max. absorption occurs at 264—300, 294 and 550, and 480 and  $< 250 \text{ m}\mu$ , respectively. F. O. H.

Optical absorption of porphyrins. IV. A. STERN and H. WENDERLEIN (Z. physikal. Chem., 1936, 175, 405—437; cf. this vol., 8).—The absorption of porphin (I), tetra- and hexa-substituted porphyrins, esters of porphyrins with higher alcohols, porphyrins having one or two groups containing CO,  $\beta\delta$ -di-iminocoproporphyrin  $\text{Me}_4$  ester, rhodin  $g_3$  Me ester, and 2-de-ethyldeoxyphyloerythrin has been determined. Alkyl substitution in (I) shifts all the band max. but one towards the red. If the absorption curve of a porphyrin is of the "rhodo" type a CO group is present in a nucleus of the (I) systems or conjugated with it. If the CO group is attached to a methine bridge of the (I) framework the absorption curve is not of the rhodo type. If there are two groups containing CO in two nuclei of the porphyrin, only those porphyrins which have the groups in the nuclei I and III or II and IV have curves of the rhodo type. The nucleus of the porphyrin system in which substitution with a group containing CO emphasises the "rhodo" character of the absorption curve has a pyrrole structure. In the formation of a monoxime of a porphyrin with two CO groups it is possible to determine from the absorption curve at which CO group the oxime has been formed. The application of these observations to the determination of configuration is discussed.

R. C.

[Absorption] spectra of solutions of chemical warfare materials. H. MOHLER and J. PÓLYA (Helv. Chim. Acta, 1936, 19, 283—287).—Preliminary. Extinction curves are given for  $\text{C}_6\text{H}_{14}$  solutions of nineteen compounds belonging to the four divisions of chemical warfare materials.

F. L. U.

Fine structure of the absorption band of water vapour at  $0.94 \mu$ . J. H. HSU (Chinese J. Physics, 1935, 1, 59—67).— $\lambda$  for 28 absorption lines are recorded, and agree with some absorption lines in

the solar spectrum. Doublet structure in agreement with a triangular  $\text{H}_2\text{O}$  mol. is indicated. L. J. J.

Hindered rotation in liquid  $\text{H}_2\text{O}$  and  $\text{D}_2\text{O}$ . C. H. CARTWRIGHT (Physical Rev., 1936, [ii], 49, 470—471).—Assuming a tetrahedral quartz-like structure for the  $\text{H}_2\text{O}$  mol., the calc. intermol. field leads to the prediction of a characteristic frequency at  $60 \mu$  due to a mutual vibration between the mols., and a frequency at  $20 \mu$  due to hindered rotation. The observed characteristics and shifts of these bands, their variations in  $\text{H}_2\text{O}$  and  $\text{D}_2\text{O}$ , and a theoretical explanation are described and discussed. N. M. B.

Structure of the infra-red absorption of crystals. F. SEITZ (Physical Rev., 1936, [ii], 49, 405; cf. A., 1935, 1444).—A correction. N. M. B.

Infra-red absorption of hydrogen chloride in non-ionising solvents. W. WEST and R. T. EDWARDS (Physical Rev., 1936, [ii], 49, 405; cf. Plyler, this vol., 406).—Observations on the infra-red absorption for the harmonic at  $1.76 \mu$  are in general agreement with results obtained from Raman spectra (cf. A., 1934, 583). Information for solutions in  $\text{PCl}_3$ ,  $\text{POCl}_3$ ,  $\text{CCl}_4$ , and  $\text{SO}_2$  is outlined. N. M. B.

Infra-red absorption spectra of mixtures of acetone and water. D. WILLIAMS and E. K. PLYLER (J. Chem. Physics, 1936, 4, 154—157).—The infra-red absorption spectra of  $\text{COMe}_2\text{-H}_2\text{O}$  mixtures have a band indicating association near  $2.7 \mu$ . The intensity of the band increases with increasing  $\text{H}_2\text{O}$  content, but  $[\text{H}_2\text{O}]$  as low as 0.1% may be detected by the presence of the band. M. S. B.

Infra-red absorption spectra of deuteroxide solutions in deuterium oxide. E. K. PLYLER and D. WILLIAMS (J. Chem. Physics, 1936, 4, 157—160).—The infra-red absorption spectra of  $\text{D}_2\text{O}$  and solutions of  $\text{NaOD}$ ,  $\text{Na}_2\text{CO}_3$ , and  $\text{K}_2\text{CO}_3$  in  $\text{D}_2\text{O}$  have been measured for the range  $2.5\text{--}9 \mu$ . Intense bands are observed in  $\text{NaOD}$  solutions at  $3.1$ ,  $4.95$ , and  $7.1 \mu$ .  $\text{Na}_2\text{CO}_3$  and  $\text{K}_2\text{CO}_3$  in  $\text{D}_2\text{O}$  also give rise to bands in these regions, but with a shift in  $\lambda$  probably due to absorption by  $\text{CO}_3^{2-}$  and  $\text{D}_2\text{CO}_3$  formed in solution. The band at  $3.1 \mu$  is attributed to  $\text{OD}'$ , corresponding with the  $\text{OH}'$  band at  $2.3 \mu$ . The two bands at  $4.95 \mu$  and  $7.1 \mu$  are probably due to hydration and correspond with the bands at  $3.65 \mu$  and  $5.2 \mu$  in hydroxide solutions (cf. A., 1934, 1154). M. S. B.

Temperature dependence of the absorption spectra of alcohols in the near infra-red, up to and above the critical point. A. NAHERNIAC (Compt. rend., 1936, 202, 649—651).—For  $\text{MeOH}$ ,  $\text{EtOH}$ ,  $\text{Pr}^\text{OH}$ ,  $\text{Pr}^\text{OH}$ , and  $\text{Bu}^\text{OH}$ , the intensity of the OH band at about  $10,000 \text{ Å}$ . increases continuously with rise of temp. The positions of the band for the liquid and vapour at const. vol. approach one another with rising temp., and coincide at the crit. temp. Thus the  $\lambda$ - $t$  curve resembles the density curve.

L. J. J.

Infra-red absorption spectrum of HDS and  $\text{D}_2\text{S}$ . A. H. NIELSEN and H. H. NIELSEN (J. Chem. Physics, 1936, 4, 229).— $\text{D}_2\text{S}$  has bands at  $3.65$ ,  $4.55$ , and  $10.8 \mu$  and HDS at  $2.1$ ,  $3.15$ ,  $4.1$ , and  $9.0 \mu$ . The  $\text{H}_2\text{S}$  bands are shifted towards longer  $\lambda$  in the anticipated manner.

M. S. B.

**Infra-red absorption spectra of chlorinated methanes.** C. CORIN (Compt. rend., 1936, 202, 747—749).—Data are recorded for 15, 15, and 18 bands in the infra-red absorption spectra of liquid  $\text{MeCl}$ ,  $\text{CH}_2\text{Cl}_2$ , and  $\text{CHCl}_3$ , respectively.  $\text{CCl}_4$  gave no bands in this region ( $0.7\text{--}2.6\ \mu$ ). The bands of  $\text{CHCl}_3$  were not observed in  $\text{CCl}_3\text{NO}_2$ , but 7 new bands, associated with the  $\text{C-NO}_2$  group and occurring for  $\text{C(NO}_2)_4$ , were observed. The intensity of absorption increases with the no. of C-H linkings in the mol. H. J. E.

**Vibration frequencies of chlorine derivatives [of some aliphatic compounds] deduced from infra-red absorption and Raman spectra.** H. C. CHENG and J. LECOMTE (Ann. Physique, 1936, [xi], 5, 427—443; cf. A., 1935, 1053).—Infra-red absorption spectra measurements in the frequency range  $640\text{--}1400\ \text{cm}^{-1}$  lead to interpretation of available Raman data and of C-Cl vibrational frequencies. The latter, in the case of  $\text{Cl}_3$ -derivatives, show marked divergence from theory, and anomalous bands are classified. N. M. B.

**Raman effect in chemistry.** G. DUPONT (Bull. Soc. chim. Belg., 1936, 45, 37—56).—A lecture.

**Raman effect and problems of constitution.**  
IX. **Stability of the aromatic C-X linking.**—See this vol., 599.

**Polarisation in the molecular diffusion spectrum of liquid carbon tetrachloride.** A. ROUSSET (Compt. rend., 1936, 202, 654—656).—Depolarisation factors  $\neq 0$  are recorded for the Rayleigh scattered radiation and the line of undisplaced  $\lambda$ , and are due, respectively, to depolarised rotational wings (Cabannes-Daure effect) and to the depolarised  $Q$  branch. This can be explained by anisotropy of the  $\text{CCl}_4$  mol., which is confirmed by the incomplete polarisation of the symmetrical vibration Raman line  $459\ \text{cm}^{-1}$  (isotopy effect of Cl), and the incomplete depolarisation and splitting of the Raman lines 219 and  $316\ \text{cm}^{-1}$ , due to dissymmetry of the C valencies. L. J. J.

**Polarisation of Raman radiation and constitution of molecules.** II. B. TRUMPY (Z. Physik, 1936, 98, 672—683).—Polarisation measurements show  $\text{Bu}^i\text{OH}$  to have  $C_{3v}$  symmetry, and give an allocation of Raman frequencies. Measurements on the Raman spectrum of  $\text{C}_2\text{H}_2\text{Br}_4$  show absence of free rotation, the *cis*- and *trans*-forms being equally probable.  $\text{C}_2\text{D}_2\text{Cl}_4$  and *cis*- and *trans*- $\text{C}_2\text{D}_2\text{Cl}_2$  have Raman spectra in agreement with their H equivs. (cf. A., 1935, 565). A. B. D. C.

**Raman effect in chemical dynamics.** W. F. BEZGHOLD and L. S. ORNSTEIN (Physica, 1936, 3, 154—172).—The Raman spectrum of transformer oil showed, after oxidation, a decrease in the intensity of the C-H oscillation lines. The photochemical chlorination of  $\text{CHCl}_3$  was followed completely by the Raman effect, the amount of  $\text{CCl}_4$  being estimated by the intensity of the lines; the reaction is independent of  $[\text{CHCl}_3]$ . A theoretical interpretation of the empirical reaction equation is given. Results are compared with those for the vapour state (cf. Schumacher, A., 1934, 740). A new method of illum-

ination and measurement by means of a photo-electric cell is described. N. M. B.

**Deformation frequencies in the Raman spectra of linear molecules: acetylene.** S. BHAGAVANTAM and A. V. RAO (Proc. Indian Acad. Sci., 1936, 3, A, 135—139).—New bands at  $\Delta\nu$  589 and 646 have been recorded with long exposure. The negligible intensity of the  $Q$  branch and the observed separation support an interpretation as the max. of the unresolved  $O$ ,  $P$ ,  $R$ , and  $S$  branches of the total symmetric deformation vibration of the mol. The mean frequency shift is in good agreement with the val. deduced from infra-red absorption. N. M. B.

**Raman spectrum of some derivatives of pyrrole.** G. B. BONINO and R. MANZONI-ANSIDEI (Atti R. Accad. Lincei, 1935, [vi], 22, 349—354).—The Raman spectra of 1-ethyl-, 1-allyl-, 1-methyl-, 2:5-diethyl-, 2:5-dimethyl-1-ethyl-, and 2:5-dimethyl-3-ethyl-pyrrole have been measured. They all give the two pyrrole ring lines at  $1460\text{--}1520$  and  $1370\text{--}1390\ \text{cm}^{-1}$ . The interpretation of other lines found is discussed. O. J. W.

**Raman spectrum of pyrrole and some derivatives.** A. STERN and K. THALMAYER (Z. physikal. Chem., 1936, B, 31, 403—419).—In the Raman spectrum of pyrrole (I) frequencies due to the  $\text{CH}_2$  group and to the C'C, C'N, and aliphatic C-H linkings have been observed. Hence even in unsubstituted (I) there must be an equilibrium between the pyrrole and pyrrolene forms. The position of equilibrium between these forms and the supposed centric form is very much in favour of the latter. The model of (I) and interpretation of the Raman spectra of its derivatives proposed by Bonino (A., 1934, 830) are criticised. R. C.

**Comparison of Raman spectra of *cis*- and *trans*-cinnamyl derivatives.** (MLLE.) B. GREDY (Compt. rend., 1936, 202, 664—666).—In contrast to the corresponding *cis*- and *trans*- $\alpha$ -derivatives of  $\Delta^8$ -octene, the *cis*- and *trans*-cinnamyl derivatives (RH, ROH, ROME, ROAc, RBr) have only one or two lines in common in their Raman spectra, apart from the  $\text{C}_6\text{H}_6$  lines. Data are recorded. The *trans*- have higher b.p.,  $n$ , and  $d$  than *cis*-derivatives. L. J. J.

**Raman spectra of some organic liquids under high dispersion and resolving power.** R. ANANTHAKRISHNAN (Proc. Indian Acad. Sci., 1936, 3, A, 52—74).—Detailed data, including a no. of new faint lines, are recorded for  $\text{C}_6\text{H}_6$ , PhMe, PhOH, PhCl,  $\text{C}_5\text{H}_5\text{N}$ , and cyclohexane.  $\nu$  and relative intensities for the line  $992\ \text{cm}^{-1}$  of  $\text{C}_6\text{H}_6$  and its satellites are: 979 ( $\frac{1}{2}$ ), 984 (1), 992.5 (10), 998 (1), 1006 ( $\frac{1}{2}$ ). The corresponding line ( $802\ \text{cm}^{-1}$ ) in cyclohexane shows no fine structure; in  $\text{C}_5\text{H}_5\text{N}$  and mono-derivatives of  $\text{C}_6\text{H}_6$  it has a faint satellite,  $\nu$  and intensity of which, however, bear no simple relation to those of the main line. It is concluded that the satellite  $984\ \text{cm}^{-1}$  in  $\text{C}_6\text{H}_6$  is not due to the  $\text{C}^{13}$  isotope. The constitution of the  $\text{C}_6\text{H}_6$  ring is considered. L. J. J.

**Raman effect.** LIV. **cyclohexyl derivatives and symmetry of cyclohexane and dioxan.**

K. W. F. KOHLRAUSCH and W. STOCKMAIR (Z. physikal. Chem., 1936, B, 31, 382—401; cf. this vol., 137).—The spectra of monosubstituted cyclohexane (I) derivatives,  $C_6H_{11}X$  ( $X=NH_2$ , OH, Me, CN, Cl, Br, I) and of (I), dioxan (II), and piperidine have been determined. Substitution depresses the ring frequencies in (I) less than in  $C_6H_6$ .  $C_6H_{11}X$  show fewer Raman lines than would be anticipated, possibly owing to "accidental" degeneracy. The results are reconcilable with the "chair" configuration for the (I) ring, but not with the trough form, or a form intermediate between the trough and chair forms and having the C atoms 1, 2, 4, and 6 in one plane. For (II) also the trough and intermediate forms are excluded. R. C.

**Raman effect of organic sulphides.** P. DONZELLOT and M. CHAIX (Compt. rend., 1936, 202, 851—852).—The Raman spectra of  $(C_6H_5)_2O$  and  $(C_6H_5)_2S$  have been compared with those of  $Ph_2O$  and  $Ph_2S$  (A., 1935, 1301) in order to study the effect of a third closed ring connecting the two  $C_6$  rings. A marked displacement of the  $C_6H_6$  frequencies takes place, and, instead of two frequencies in the neighbourhood of 1000, as in  $Ph_2O$ ,  $Ph_2S$ , and some other  $C_6H_6$  derivatives, there is one only for  $(C_6H_5)_2O$  and  $(C_6H_5)_2S$ . Raman spectra of  $Et_2S$ ,  $Et_2S_2$ , and  $Et_2S_3$  indicate that the frequencies in the neighbourhood of 635, 655, 960, 1045, and 1150 are associated with the C-S linking, and that the frequency 179, associated with the S-S linking in  $Et_2S_2$ , is doubled, giving 151 and 204, in  $Et_2S_3$ . A frequency in the neighbourhood of 500 is probably associated with S-S in both compounds. M. S. B.

**Raman spectrum of tetraethylsilane. Vibrational resonance of tetra-alkyls.** T. F. ANDERSON (J. Chem. Physics, 1936, 4, 161—164).—The Raman spectrum of  $SiEt_4$  is given together with the data available for other tetra-alkyl compounds and assignments of frequencies are made. The presence of extra lines in the spectra is explained by resonance between vibrations. First-order perturbation calculations of the observed resonance effects are given. M. S. B.

**Molecular clustering in liquid fatty acids.** R. S. KRISHNAN (Proc. Indian Acad. Sci., 1936, 3, A, 126—134; cf. A., 1935, 11).—The intensity and depolarisation of light scattered transversely by dust-free samples of  $HCO_2H$ ,  $AcOH$ ,  $EtCO_2H$ , and  $Pr^iCO_2H$  are measured between  $20^\circ$  and  $90^\circ$ . The depolarisation of the horizontally polarised light is high for  $HCO_2H$  and  $AcOH$  and is greatest at room temp. In opposition to the theory of mol. scattering, the depolarisation decreases with rising temp. These anomalies show the presence in the liquids, at low temp., of mol. aggregates of a size comparable with the  $\lambda$  of light. Anomalies in the optical anisotropy of  $HCO_2H$  and  $AcOH$  in the liquid and vapour state observed by Ramanathan (Indian J. Physics, 1926, 1, 401) and Rao (A., 1928, 1311) are explained. No evidence is obtained of the presence of mol. clusters in  $EtCO_2H$  and  $PrCO_2H$ . O. D. S.

**Slightly modified scattered radiation of crystals and the characteristic vibrations of the molecules in the lattice.** M. VUKS (Compt. rend.

Acad. Sci. U.R.S.S., 1936, 1, 73—76; cf. A., 1935, 281, 564, 914).—The scattered spectra of the  $\alpha$  and  $\beta$  modifications of  $p-C_6H_4Cl_2$  show marked differences, whilst the usual Raman spectrum is found for both forms to be identical with that for the liquid substance. This is held to support the theory that the "wings" in the Raman spectra are produced by the linkings between mols. in the lattice, and give the characteristic vibrations of the mol. The Raman spectra of the isomorphous  $p-C_6H_4Cl_2$  and  $p-C_6H_4Br_2$  are compared. A. J. M.

**Selective light scattering in mercury vapour.** G. LANDSBERG and L. MANDELSTAM (Physikal. Z. Sovietunion, 1935, 8, 378—400).—The selective scattering at 2558 Å. of Hg is studied and a method is given for investigating the mol. and at. parts of the radiation. The intensity of the at. part agrees with the theoretical val. The mol. part is feebly polarised and the at. part almost completely polarised. The extinguishing effect of  $N_2$  is slight. W. R. A.

**Longitudinal scattering of light according to Plotnikov.** M. KATALINIĆ (Kolloid-Z., 1936, 74, 288—296).—A crit. discussion of published work. E. S. H.

**Raman effect of ammonia.** P. DAURE, A. KASTLER, and H. BERRY (Compt. rend., 1936, 202, 569—572).—The Raman spectra of gaseous, liquid, and aq.  $NH_3$  have been investigated and the polarisation has been determined. The spectrum in liquid  $NH_3$  is ascribed to association, which is destroyed by  $H_2O$ , probably in two stages. T. G. P.

**Raman spectra of sulphates at different concentrations.** S. M. MITRA (Z. Physik, 1936, 98, 740—741).—Variation of Raman displacements with concn. of  $Li_2SO_4$  and  $MgSO_4$  observed by Embrikos (A., 1930, 1499) could not be detected. A. B. D. C.

**Raman spectra of orthophosphoric acid and some phosphates.** C. S. VENKATESWARAN (Proc. Indian Acad. Sci., 1936, 3, A, 25—30).— $H_3PO_4$  at concns. 3—85% shows new lines indicating ionisation to  $H^+ + H_2PO_4^+$  and  $2H^+ + HPO_4^{++}$ , as well as weak lines due to OH vibrations. For  $MH_2PO_4$ ,  $M_2HPO_4$ , and  $M_3PO_4$  ( $M=Na$ ,  $K$ , and  $NH_4$ ), spectra due to  $H_2PO_4^+$ ,  $HPO_4^{++}$ , and  $PO_4^{+++}$  have been identified. Comparison with data for sulphates and selenates indicates tetrahedral structure for  $PO_4^{+++}$ . L. J. J.

**Raman spectra of organic borates.** M. S. JOGLEKAR and V. N. THATTE (Z. Physik, 1936, 98, 692—701).—Raman lines are given for Me, Et, Bu, amyl, isoamyl, and Ph borates. Some  $BO_3$  frequencies appear in the org. borate spectra, indicating similarity of  $BO_3^{+++}$  and  $B(OR)_3$ . A. B. D. C.

**Fluorescence of sodium salicylate.** G. DEJARDIN and L. HERMAN (Compt. rend., 1936, 202, 651—654).—The spectrum of the diffused light from cryst. Na salicylate irradiated with the continuous  $H_2$  spectrum is continuous, with weak intensity max. at  $\lambda\lambda$  2500, 2700, and 3300 Å., in addition to the fluorescence band in the blue-violet. With the Hg line 2482 Å., only the fluorescence band can be distinguished; the energy distribution in this band is independent of the incident  $\lambda$  for  $\lambda\lambda$  3130—2537 Å. L. J. J.

**Displacement of fluorescence and absorption spectra of tribenzyldecacyclene in relation to the solvent.** P. MARGULIES (*Acta phys. polon.*, 1934, 3, 373—384; *Chem. Zentr.*, 1935, ii, 31).—From measurements in 26 solvents connexions are traced between the displacement of the spectra and the properties of the solvent. H. N. R.

**Absorption and fluorescence spectra of a dicinnamoylmethane derivative and the carrier of this fluorescence.** E. RAKOWER (*Acta phys. polon.*, 1934, 3, 415—420; *Chem. Zentr.*, 1935, ii, 32).—The spectra of Me 3-cinnamoylacetyl coumarin-7-carboxylate, dicinnamoylmethane, and coumarin are described and discussed. H. N. R.

**Influence of viscosity and temperature on fluorescent power.** J. BOUCHARD (*J. Chim. phys.*, 1936, 33, 232—246).—The extinction coeff. ( $k$ ) of the fluorescence of a solution, corr. for its variation due to changes in the sp. inductive power of the medium, decreases with increasing viscosity ( $\eta$ ) of the medium. The  $k$ - $\eta$  curve is analogous to a velocity of diffusion  $\eta$  curve, in accord with the view relating the decay in fluorescence with the concn. and velocity of diffusion of fluorescent mols. Perrin's law represents satisfactorily the variation of fluorescent power ( $\Phi$ ) as a function of concn. at 2—80°. The extrapolated val. of  $\Phi$  for rhodamine-B decreases with rise of temp., but for uranine, eosin, erythrosin, and acridine-yellow it is approx. const.  $k$  increases with rise of temp. for solvents of low inductive power (alcohols,  $\text{COMe}_2$ , etc.), probably owing to the low association in these solvents and the increased probability of collision between dissolved mols. at higher temp. For aq. solutions  $k$  decreases with rising temp., probably because the extinction of fluorescence depends on the presence of associated mols., the concn. of which decreases with rising temp. J. W. S.

**Influence of specific inductive capacity on fluorescent power. I. Influence of the specific inductive capacity of the solvent on the decrease of fluorescent power as a function of the concentration of fluorescent material. Uranine. II. Fluorescent materials other than uranine.** J. BOUCHARD (*J. Chim. phys.*, 1936, 33, 127—149; cf. this vol., 408).—The fluorescence of uranine in aq. mixtures of MeOH, EtOH,  $\text{Pr}^n\text{OH}$ ,  $\text{Bu}^n\text{OH}$ ,  $\text{C}_5\text{H}_5\text{N}$ , and  $\text{COMe}_2$  containing 0.1N-NaOH has been studied. The fluorescent power,  $\Phi$ , varies with concn.,  $c$ , and composition of the solvent according to Perrin's law,  $\Phi = \Phi_0 e^{-kc}$ , whilst the extrapolated fluorescent power,  $\Phi_0$ , is approx. const. Determinations of the dielectric consts. of the solvents lead to the relation  $k = 1/(A - B\epsilon)$  where  $A$  and  $B$  are consts. Eosin, acridine-yellow, rhodamine-B, -G, -S, -3B, and -6G behave similarly. In the case of rhodamine-B in EtOH- $\text{CCl}_4$  mixtures,  $k$  increases with  $[\text{CCl}_4]$  as if this acted only as a diluent. R. S.

**Theories of phosphorescence.** M. CURIE (*Compt. rend.*, 1936, 202, 751—753).—A discussion. H. J. E.

**Spectrum of the thermoluminescence of fluorite.** H. STEINMETZ and A. GISSER (*Naturwiss.*, 1936, 24, 172).—In contrast to the thermolumin-

escence spectra of most minerals, which are continuous, that of  $\text{CaF}_2$  is composed of several bands, the  $\lambda\lambda$  of which are given. A. J. M.

**Inner photo-effect with semi-conductors.** H. FRÖHLICH (*Physikal. Z. Sovietunion*, 1935, 8, 501—510).—The electron distribution function for a semi-conductor illuminated with monochromatic light is calc., and the result is confirmed by consideration of the Demer effect. A. J. M.

**Influence of temperature on the photo-electric effect of the metal-cuprous oxide interface.** J. ROULLEAU (*Compt. rend.*, 1936, 202, 749—751).—Anomalies in the temp. variation of the photopotential are explained by the simultaneous temp. variation of the contact resistance and of the photopotential. H. J. E.

**Photo-electric activity of iron and its oxides.** J. S. HUNTER (*Nature*, 1936, 137, 460; cf. A., 1935, 682).—The surface of  $\text{Fe}_2\text{O}_3$  is photo-electrically insensitive. The spectral distribution curve for FeO showed a max. at 2190 Å. with a photo-electric threshold at  $< 2500$  Å. The results support a theory of gas adsorption, in preference to instantaneous oxidation, as the initial change undergone by a clean metal surface on exposure to air. L. S. T.

**Electrical behaviour of cuprite crystals.** P. BRAUER (*Ann. Physik*, 1936, [v], 25, 609—624).—The resistance and Hall const. of  $\text{Cu}_2\text{O}$  crystals increase with the partial pressure of  $\text{H}_2\text{O}$  vapour in the surrounding atm., a surface effect due to variation in the concn. of conductivity electrons. The effect of  $\text{H}_2\text{O}$  vapour is not associated with any detectable change in the cryst. structure. L. J. J.

**Primary photo-electric current in NaCl crystals.** W. THIELE (*Ann. Physik*, 1936, [v], 25, 561—568).—Irradiation of rock-salt crystals containing absorption centres (free Na atoms) with  $\lambda\lambda$  405 and 436 m $\mu$  gives rise to a new absorption band in the infra-red. Subsequent irradiation with  $\lambda > 800$  m $\mu$  gives a photo-electric effect which decays with time. It is concluded that some of the electrons initially liberated from Na atoms combine with positive ions to form new loosely bound absorption centres. The half-life period of these centres diminishes as the temp. is raised. L. J. J.

**Destruction of an adsorbed rectifying film by pressure.** F. TREY (*Physikal. Z.*, 1936, 37, 213—214).—Pressure of 4000 kg.-per sq. cm. on a rectifying PbS pastille destroys its rectifying powers. A. J. M.

**True conductivity and back e.m.f. in layered dielectrics.** F. QUITTNER (*Physikal. Z. Sovietunion*, 1935, 8, 275—278; cf. A., 1930, 1504).—A model consisting of alternate thick and thin layers of good and bad conductivity is discussed in relation to previous experimental data on rock-salt. The simple form of model does not account for the results. R. S.

**Normal cathode fall at the m.p. of bismuth.** H. KURZKE (*Ann. Physik*, 1936, [v], 25, 688—696; cf. A., 1934, 1291).—Bi shows a decrease (2 volts with a normal cathode fall of 160 volts) in passing from solid to liquid, in contrast to Sn and Pb. This corre-

sponds with a change of 0.05 volt in the emission energy. L. J. J.

**Substances of low conductivity, and the Rebooul effect.** O. VIKTORIN (Chem. Listy, 1936, 30, 60—64).—A discussion. R. T.

**Abnormal electrical conductivity in powdered tellurium.** C. H. CARTWRIGHT (Physical Rev., 1936, [ii], 49, 443—448).—Under 1000 kg. per sq. cm. pressure Te powder had about 10 times greater conductivity than that of a single crystal under the same pressure. The anomaly was most marked in pure Te, disappearing, probably due to masking, in presence of impurities. Momentary passage of an electric current through the powder under pressure diminished its vol., and greatly decreased its conductivity. Under 20,000 kg. per sq. cm. hydrostatic pressure massive Te increases in conductivity > 100 times, and the rate of increase rises rapidly with pressure. The anomaly may be due to local pressures in excess of the measured average; other explanations are discussed.

N. M. B.

**Electrical conductivity of cuprous oxide in strong electric fields.** M. D. BORISSOV, I. I. KARA, and K. D. SNELENIKOV (Physikal. Z. Sovietunion, 1935, 8, 425—429).—Using different field strengths the increase in conductivity depends on the no. of conducting electrons. W. R. A.

**Mechanism of electrical conduction of solid ionic conductors.** A. SMEKAL (Physikal. Z., 1936, 37, 150—153).—The theory of Schottky (A., 1935, 1302, 1305) is discussed. The equation used by Schottky *et al.* for the polarisation effect is not applicable. According to the theory, in ionic conduction, an ion jumps from its place to a void in the lattice. The probability of this will depend on the properties of the ion and the frequency of the thermal vibrations of the lattice. When equal nos. of cationic and anionic voids are present, differences in mobilities of the ions must be due only to differences in properties of the ions. It is not necessary to assume any different mechanism for the conduction of AgCl and AgBr, where it is entirely cationic. Since lattice conduction is due to disorder phenomena, and these can be "frozen," it should be possible to observe unstable conditions of conduction at low temp. Reversible low-temp. decreases in conduction are therefore not always to be ascribed to electrolytic purification. This is probably the explanation of Kassel's experiments with rock-salt (A., 1934, 1163).

A. J. M.

**Breakdown with internal photo-electric effect.** I. M. GOLDMAN and B. M. VUL (Physikal. Z. Sovietunion, 1935, 8, 369—377).—For rock-salt crystals changes in electronic conductivity within a large range do not influence the dielectric strength. Stained crystals give lower breakdown potentials with d.c. and a.c. when subjected to light; this is due to secondary factors. W. R. A.

**Dielectric constant of wool fibre.** F. W. HOLL (Helv. Chim. Acta, 1936, 19, 281—283).—The dielectric const. of washed and fat-free Cape wool, determined by the bridge-condenser method, is  $4.56 \pm 10\%$ . F. L. U.

**Dielectric constant and electrostriction of amino-acids and peptides.** J. P. GREENSTEIN and J. WYMAN, jun. (J. Amer. Chem. Soc., 1936, 58, 463—465; cf. A., 1935, 694).—Data for *l*-asparagine, acetylhistidine, glycyl-leucine, alanyl-, *N*-methyl-leucyl-, glycyl-, and glycylphenyl-alanine, leucyl-, phenylalanyl-, and leucylglycyl-glycine are recorded. E. S. H.

**Determination of dielectric constants and dipole loss at high frequencies.** I. Introduction. M. WIEN. II. Dipole loss in liquids for long waves. C. SCHRECK. III. Determinations with sucrose and fructose solutions. W. DAHMS. IV. Determinations with different kinds of glass. W. HACKEL. V. Determination of losses in different liquids by the thermometer method. C. SCHMELZER (Physikal. Z., 1936, 37, 155—156, 156—158, 158—160, 160—162, 162—164).—I. Results previously obtained for the behaviour of liquids in powerful and high-frequency electric fields are summarised. The most important results of the Debye theory of dipole loss are collected.

II. Determinations of dipole loss were made using the barretter method with a non-polar liquid ( $C_6H_6$ ) and polar liquids (aq. solutions of sucrose and fructose,  $Bu^oOH$ ). The variation of dipole conductivity ( $\Delta\chi$ ) with  $\lambda$  was linear in the case of  $Bu^oOH$  and sucrose. For dil. solutions of fructose  $\Delta\chi \propto 1/\lambda^2$ , but for conc. solutions  $\Delta\chi \propto 1/\lambda$ . There was no loss in  $C_6H_6$ .

III. Aq. solutions of sucrose and fructose give qual. agreement with theory as regards variation of  $\Delta\chi$  with  $1/\lambda^2$  for short  $\lambda$ , but deviations occur with more conc. solutions. Similar results are obtained as for long  $\lambda$  (see above). There is a considerable decrease of dielectric const. ( $\epsilon$ ) of fructose solutions with increase of  $d$  of solution. This is not found for sucrose, contrary to theory. The deviations of the dipole effect from theory may be due to inhomogeneity, or to the possibility that the Debye theory is not accurate for very viscous solutions.

IV. A method for the simultaneous determination of  $\epsilon$  and conductivity ( $\chi$ ) of solids is described in which the solid is placed between the plates of a condenser filled with a liquid of which the  $\epsilon$  and  $\chi$  are varied until they are the same as those of the solid.  $\epsilon$  and  $\chi$  of the liquid are then determined. The method was used with various Jena (Schott) glasses over the  $\lambda$  range 12,000—10 m. The high-frequency  $\chi$  is strongly dependent on the kind of glass. At first  $\chi \propto 1/\lambda$  but with shorter  $\lambda$  it increases more slowly than this. The variation of  $\epsilon$  with  $\lambda$  is different for the different glasses, and although there are deviations from the Debye theory, the phenomena can still be explained as connected with dipole loss. The results are compared with those obtained for fructose solutions (see above).

V. The thermometer method of Harms and Malsch (A., 1932, 214) was used to determine the high-frequency  $\chi$  and dipole loss ( $\Delta\chi$ ) of various liquids. Non-polar substances (e.g., dioxan) show no loss. For  $Pr^oOH$   $\Delta\chi \propto 1/\lambda^2$ , although the slope of the curve between  $\Delta\chi$  and  $1/\lambda^2$  is > theory; this, however, is accounted for. Solutions of  $HgCl_2$  and  $AcOH$  in  $CO_2$  show a considerable increase in  $\chi$  at high frequency above that at low frequency. This is

due to formation of ion pairs of large dipole moment. A solution of  $\text{NBu}_4^+\text{Br}^-$  in  $\text{C}_6\text{H}_6$  behaves similarly.  $\Delta\chi$  in this case depends on field strength, which causes alteration in the no. of ion pairs. A. J. M.

**High-frequency loss of polar solutions.** G. MARTIN (Physikal. Z., 1936, 37, 164—165).—If dissolved mols. are regarded as spheres rotating in a viscous medium, an expression connecting relaxation time with coeff. of viscosity ( $\eta$ ) and size of mols. can be obtained on the basis of Stokes' law.  $\text{C}_6\text{H}_6$  solutions of *o*-, *m*-, and *p*- $\text{C}_6\text{H}_4\text{Cl}_2$  show a high-frequency loss  $\propto$  (dipole moment)<sup>2</sup>. The effect of size of mol. was investigated with  $\text{PrOH}$ , hexyl, octyl, and cetyl alcohols in dil.  $\text{C}_6\text{H}_6$  solutions. The loss, extrapolated to infinite dilution, increased linearly with the no. of C in the alcohol mol. The results agree with theory. The effect of  $\eta$  was investigated with solutions of *o*- $\text{C}_6\text{H}_4\text{Cl}_2$  in  $\text{C}_6\text{H}_{14}$ ,  $\text{C}_6\text{H}_8$ ,  $\text{CCl}_4$ , and decalin. The relaxation time was not accurately  $\propto \eta$  as required by theory.

A. J. M.

**Dielectric losses at high frequency in liquids.** M. DIVILKOVSKI and M. FILIPPOV (Physikal. Z. Sovietunion, 1935, 8, 311—318).—The dielectric losses in  $\text{EtOH}$ ,  $\text{Pr}^n\text{OH}$ , and glycerol have been obtained by determination of the expansion of the liquid in a thermometer vessel when placed in a high-frequency electric field. No rise of temp. could be observed in the case of  $\text{C}_6\text{H}_6$ .

R. S.

**Electric moments of solute molecules.** E. A. GUGGENHEIM (Nature, 1936, 137, 459—460).—The new formula deduced is claimed to give vals. more accurate than the Clausius-Mosotti formula when applied to the experimental data of other investigators.

L. S. T.

**Calculation of various physical constants of heterogeneous substances. II. Dielectric constants and conductivities of polycrystals of non-regular systems.** D. A. G. BRUGGEMAN (Ann. Physik, 1936, [v], 25, 645—672).—The theory (this vol., 151) developed for mixtures of isotropic substances is extended to anisotropic aggregates. The new theory gives vals. in agreement with existing data for the dielectric const. of S and  $\text{CaCO}_3$  polycrystals and suspensions in liquids, and for  $\text{BaSO}_4$ -air and  $\text{PbCl}_2$ -air mixtures. The influence of texture in the case of Sb, Bi, Sn, Cd, and Zn polycrystals explains anomalies in existing conductivity data.

L. J. J.

**Minimum estimate of the dipole moments of two oxonium salts.** (MRS.) C. G. LE FÈVRE and R. J. W. LE FÈVRE (J.C.S., 1936, 398—399).—2-Phenyl- and 2-phenyl-3-methyl-benzopyrylium perchlorates in  $\text{NPhMe}_3$  at  $25^\circ$  have dipole moments at least about 8 and 7, respectively. Four pyrylium ferriehlorides are sol. in  $\text{NPhMe}_3$  but have very high  $\kappa$ .

R. S. C.

**Dipole moment and solvent.** K. HIGASI (Sci. Papers Inst. Phys. Chem. Res. Tokyo, 1936, 28, 284—309).—The polarising influence of an ellipsoidal dipole with an axis of symmetry ( $c$ ) on a non-polar solvent is considered. The dipole moment of the solute in solution,  $\mu'$ , is given by  $\mu + 4\pi n\alpha A\mu$ , where  $\mu$  is the moment in the gaseous phase,  $n$  is the no. of

solvent mols. per c.c.,  $\alpha$  is the polarisability of the solvent, and  $A$  is dependent only on the shape of the solute mol. If  $a$  is the axis perpendicular to the symmetry axis,  $\mu'$  is  $>$ ,  $=$ , or  $< \mu$  according as  $a$  is  $<$ ,  $=$ , or  $> c$ ; Müller's theory considers only the case  $\mu' < \mu$ . Examples agree with theory,  $\text{CHCl}_3$ ,  $\text{Et}_2\text{O}$ , and the alcohols (data of Higasi) in  $\text{C}_6\text{H}_6$  and  $\text{C}_6\text{H}_{12}$  giving  $\mu' > \mu$ . The shape of the mols. is considered in relation to X-ray evidence, optical polarisabilities, and Kerr const.; in general negative vals. of the Kerr const. are correlated with  $\mu' > \mu$ .  $\mu'$  can be "corr." for solvent effect by plotting  $\mu'$  against  $(\epsilon - 1)/(\epsilon + 2)$  ( $\epsilon$  is dielectric const. of solvent), the slope of  $\mu'/\mu - 1$  against  $(\epsilon - 1)/(\epsilon + 2)$  being positive or negative, and extrapolating to  $\epsilon = 1$ . If extrapolation is not possible the solvent with the smallest  $\epsilon$  gives the best val. for  $\mu$ .

R. S. B.

**Steric configuration and the condition of strain of some ring compounds.** J. BÖESEKEN (Chem. Weekblad, 1936, 33, 206—214).—The importance of the study of dipole moments (in parentheses), the formation of *B*-compounds, and the velocity of the

reaction  $>\text{C}:\text{C} + \text{AcO}_2\text{H} \rightarrow \text{---}\text{C}\text{---}\text{C}\text{---}\text{O} + \text{AcOH}$ , for determining stereochemical configurations are discussed and applied to dioxan (0.3), tetra-, m.p.  $61-64^\circ$  (1.85), 99.5—101.5° (1.05), 143—144° (0), hexachlorodioxan (0), naphthodioxans, m.p.  $111^\circ$  (1.90),  $136^\circ$  (0.72), pyrocatechol dimethylene ether (1.40), and several cyclic hydrocarbons including terpenes. The mol. wt. of metaldehyde is twice that of paraldehyde.

S. C.

**Dipole moment and structure of organic compounds. XV. Electric moments of some chlorinated naphthalenes.** G. C. HAMPSON and A. WEISSBERGER (J.C.S., 1936, 393—398).—Data are recorded for the two  $\text{C}_{10}\text{H}_7\text{Cl}$  and the ten  $\text{C}_{10}\text{H}_6\text{Cl}_2$  in  $\text{C}_6\text{H}_6$  solution at  $25^\circ$ . The C-Cl moment in 2- $\text{C}_{10}\text{H}_7\text{Cl}$  (1.65D) is approx. the same as in  $\text{PhCl}$ , whilst in the 1-position it is less (1.51D).  $\mu$  is 0.48D for 1:4- $\text{C}_{10}\text{H}_6\text{Cl}_2$ , but zero for the 1:5- and 2:6-isomerides. There is no evidence of fixation of single and double linkings. The results indicate that each C-Cl is directed as from the centre of the ring, and induces in the rest of the mol. a moment corresponding with the calc. polarisability of the system, including an "ortho-effect" when two Cl are close together.

L. J. J.

**Structure of anisotropic liquids.** R. D. SCHULVAS-SOROKINA and M. V. POSNOVA (Physikal. Z. Sovietunion, 1935, 8, 319—325).—The dielectric const. of *p*-azoxyanisole is unaffected by electrical fields of frequencies  $10^3-35$  Hertz. The conductivity-temp. curve is inflected at  $116^\circ$  and  $136^\circ$  corresponding with the change from the supercooled state and the change anisotropic-isotropic state, respectively.

R. S.

**Molecular volume of normal liquids.** R. LAUTIE (Compt. rend., 1936, 202, 753—754; cf. A., 1935, 435, 814).—The val. of  $K$  in the expression  $(T_c/\theta) \log (240/V_c) = K$  is always  $< 3$  for the rare gases or for light mols. or mols. containing few atoms. For associated liquids it is  $> 3$ . Typical vals. are given.

H. J. E.

**Werner complexes.** Optical activity and configuration of ions containing the groups  $[\text{Me en}_2]$  or  $[\text{Me ox}_2]$ . J. P. MATHIEU (Bull. Soc. chim., 1936, [v], 3, 476—498).—The optical rotation and circular dichroism of 20 complexes of Co, Cr, and Ir have been studied in the visible region. The bearing of the results on the configuration of the ions is discussed. E. S. H.

**Heats of combustion and refractivity data of crotonic esters.** E. SCHJÄNBERG (Z. physikal. Chem., 1936, 175, 342—346).—The energy of cleavage of the C-C linking, calc. from the heats of combustion, shows slight constitutive variations. The refractive and dispersive increments of the linking are  $\gg$  the vals. calc. from Eisenlohr's at. refractions, and the increments for normal, *iso*-, and *sec*.-esters are all different. R. C.

**Magnetic rotatory power of nitric oxide.** H. BIZETTE and B. TSAI (Compt. rend., 1936, 202, 648—649).—The Verdet const. for NO is  $-0.0068'$  for the Hg green line at  $16^\circ$  and 90 kg. per sq. cm. Data for the variation of the magnetic rotation with  $\lambda$  are given. L. J. J.

**Absolute determination of the magnetic rotatory power of water.** R. DE MALLEMANN, P. GABIANO, and F. SUHNER (Compt. rend., 1936, 202, 837—838).—Verdet's const.,  $A$ , for  $\text{H}_2\text{O}$  for the green Hg line is  $(1.543' \pm 0.001) \times 10^{-2}$  at  $11.5^\circ$ . The val. of  $A$  calc. from this for the  $D$  line, using the known val. of the dispersion, is  $1.312 \times 10^{-2}$ , in agreement with the val. obtained by other investigators. M. S. B.

**Magneto-optical dispersion of acetylacetone.** L. SHUEQ-SHANN (Chinese J. Physics, 1935, 1, 54—58).—Data for magneto-optical dispersion and Verdet const., measured in a field of 6000 gauss, are recorded.  $M[\alpha]$ , and  $e/m$  calc. from the data, are compared with calc. and accepted vals., respectively. L. J. J.

**Optic moments of organic molecules in relation to crystalline and magnetic birefringence.** M. RAMANADHAM (Proc. Indian Acad. Sci., 1936, 3, A, 43—50; cf. A., 1935, 565).—Vals. of  $C_M$  are recorded for  $\text{C}_{10}\text{H}_8$ ,  $\text{Ph}_2$ , acenaphthene, benzil, salol,  $\text{COPh}_2$ , and phenanthrene, in  $\text{CCl}_4$  solution. For  $\text{C}_{10}\text{H}_8$ , observed vals. of  $C_M$  agree with vals. calc. from Salceanu's data for the fused state (A., 1932, 561). For  $\text{Ph}_2$ , the results of Groth for the positions of the optic axes, and of Hendricks and Jefferson (A., 1933, 1104) for  $n$ , are confirmed. The direction of max.  $n$  coincides with the length of the mol., making an angle  $20^\circ 42'$  with the crystallographic  $c$  axis. The optic moments  $b_1, b_2, b_3$  (length, breadth, and thickness of mol.), calc. from  $n$  in  $\text{CCl}_4$  solution, are 33.32, 23.06, and 12.13 ( $\times 10^{-24}$ ) c.g.s., respectively, for  $\text{Ph}_2$ , and 32.36, 23.74, and 14.36 ( $\times 10^{-24}$ ), respectively, for  $(\text{CH}_2\text{Ph})_2$ , in agreement with  $n$  for the liquids, and in the case of  $\text{Ph}_2$  with the observed  $C_M$ . L. J. J.

**Linking of magnesium oxide.** H. LESSHEIM and R. SAMUEL (Current Sci., 1936, 4, 584—586).—Mols. of  $\text{MgO}$ ,  $\text{CaO}$ , etc. crystallise with the NaCl type of lattice, yet do not show ionic properties. It is suggested that it is possible for a covalent non-ionic mol. to crystallise in this type. The infra-red absorp-

tion spectrum of  $\text{MgO}$  contains several main max. and in its gross structure appears to be much too complicated for a symmetrical cubic lattice, resembling more that of the hexagonal  $\text{BeO}$  lattice. It is therefore possible that the  $\text{MgO}$  crystal is a giant mol. with covalent linkings. The assumption that the NaCl lattice is a rigorously valid criterion of the electrovalent linking is criticised on the ground that many examples are known of substances crystallising in the same lattice type, yet possessing quite different linking forces. A. J. M.

**Symmetry of the benzene molecule.** P. TERPSTRA and W. J. VAN WEERDEN (Rec. trav. chim., 1936, 55, 161—169; cf. this vol., 274).—Consideration of available data leads to the conclusion that the symmetry of the  $\text{C}_6\text{H}_6$  mol. is either  $D_{3d}$  or  $D_{6h}$ , the former being the more probable. Models are suggested and discussed. F. L. U.

**Chemical constitution of planetary atmospheres.** K. WURM (Chem.-Ztg., 1936, 60, 266—268).—A review.

**Rearrangement of molecules in unimolecular films.** Polycyclic compounds of the five-ring series. W. D. HARKINS, H. E. RIES, jun., and E. F. CARMAN (J. Chem. Physics, 1936, 4, 228—229).—In unimol. films of certain compounds such as betulin, containing five  $\text{C}_6\text{H}_6$  rings, an increase in pressure is followed by a rapid rearrangement of the mols. resulting in an almost complete disappearance of the pressure increase. M. S. B.

**Distribution of molecules in a model liquid.** W. E. MORRELL and J. H. HILDEBRAND (J. Chem. Physics, 1936, 4, 224—227).—A three-dimensional model mol. assemblage has been constructed and employed to determine the relative frequency of occurrence of different intermol. distances. The model can also be made to simulate thermal expansion. The distribution is similar to that observed by Menke in liquid Hg by X-ray diffraction (A., 1932, 986). M. S. B.

**Virial theorem and the theory of fusion.** E. L. HILL (Physikal. Z. Sovietunion, 1935, 8, 401—406).—The force function used to describe the mutual interactions between mols. is discussed, and it is emphasised that this function contains a contribution from the kinetic energy terms of the electrons. From this fact, with further simplifying assumptions about the process of melting, a schematic explanation of the observed changes in kinetic and potential energies of the mols. along the melting curve is proposed. W. R. A.

**Some relationships between atomic lattices.** E. L. FEINBERG (Physikal. Z. Sovietunion, 1935, 8, 407—415).—An approximation of the metallic crystal by means of a space lattice formed by the ions, the inter-ion space being filled with the gas of free electrons, and the division of the crystal into the Wigner and Seitz spherically-symmetrical cells, permits determination of the interat. distance which corresponds with the stable state of the crystal expressed as the function of the valency  $z$  of the element. In this way the dependence of the valency on the at. vol. is obtained and Lothar Meyer's at. vol. curve is ex-

plained. Also, the dependence on the valency of the energy of the ionisation which deprives the atom of all its  $z$  valency electrons is obtained, in good agreement with experimental data. W. R. A.

**Theory of the accommodation coefficient.** L. LANDAU (Physikal. Z. Sovietunion, 1935, 8, 489—500; cf. Jackson *et al.*, A., 1932, 1074; 1934, 6).—Calculation of the accommodation coeff.  $\alpha$  on classical lines gives  $\alpha \propto T^{3/2}$  for  $T$  not too great and for  $(h/2\pi)\eta \ll kT$ , where  $\eta$  is collision frequency. Where  $(h/2\pi)\eta \gg kT$  a quantum treatment gives  $\alpha \propto T^3$ .

A. J. M.

**Possibility of applying the Thomas-Fermi method to the problem of metallic cohesion.** E. L. FEINBERG (Physikal. Z. Sovietunion, 1935, 8, 416—424).—Mathematical. The energy of the crystal calc. on the basis of the Thomas-Fermi method, when expressed as a function of the interat. distance, has no min. and confirms the calculations of the energy curve (Slater, Krutter). The Thomas-Fermi method does not explain the stability of the crystal lattice.

W. R. A.

**Heitler-London repulsive state of hydrogen.** H. M. JAMES, A. S. COOLIDGE, and R. D. PRESENT (J. Chem. Physics, 1936, 4, 187—193).—Theoretical.

M. S. B.

**American measurements on supercooled steam.** M. JAKOB (Z. tech. Physik, 1935, 16, 83—86; Chem. Zentr., 1935, ii, 22—23).—Yellott's curve for the spontaneous condensation of ion- and dust-free  $H_2O$  vapour indicates that condensation occurs on nuclei 1.5—2 times the radius of unassociated  $H_2O$  mols., in agreement with Wilson's theory that associated mols. are involved.

J. S. A.

**Calculation of surface tension from experiment.** II. [Capillary] rise in tubes of circular section of all widths. III. Height of the meniscus in wide or narrow tubes when the angle of contact is zero; or the determination of the capillary constant for sessile drops of all sizes. A. W. PORTER (Phil. Mag., 1936, [vii], 703—706, 706—708; cf. A., 1933, 250).—II. A satisfactory correction of Richards and Coombs' formula (A., 1915, ii, 522) can be obtained by using Bashford and Adams' tables and extending these by Rayleigh's formula for very wide tubes.

III. The treatment developed previously can be extended by Bashford and Adams' tables to include very narrow capillaries or very small sessile drops.

J. W. S.

**Parachor and chemical constitution. Structure of nitrobenzyl-dialkylamines.** B. SINGH and A. SARUP (J. Chim. phys., 1936, 33, 183—187).—The surface tensions,  $d$ , and parachors of *o*-, *m*-, and *p*-nitrobenzyl-dimethyl-, -dipropyl-, and -dibutylamine are given. The parachors of the *o*-compounds correspond to a non-co-ordinated mol. structure.

R. S.

**Double refraction of X-rays in crystals.** J. FRENKEL (Physikal. Z. Sovietunion, 1935, 8, 587—588).—The failure of Hertzrücken *et al.* (*ibid.*, 1933, 4, 50) to detect double refraction of X-rays in quartz is due to the fact that the  $\lambda$  of X-rays is  $<$  interat. distances. This, as well as some other optical effects

due to anisotropy of separate mols., cannot occur with X-rays, since the electrostatic interaction of the atoms vanishes compared with the radiative interaction, and the latter is unable to give rise to anisotropy.

A. J. M.

**Distribution of electron density and potential in a crystal lattice from X-ray data.** V. E. LASCHKAREV (Physikal. Z. Sovietunion, 1935, 8, 227—239; cf. A., 1935, 1308).—A new method of calculation is described.

R. S.

**Calculation of potential distribution in certain crystal lattices.** V. E. LASCHKAREV and A. S. TSCHABAN (Physikal. Z. Sovietunion, 1935, 8, 240—254; cf. preceding abstract).—The potential distributions in Li, Al, NaCl, and diamond have been calc.

R. S.

**Distribution of X-ray reflexions from a crystal lattice.** W. KOSSEL (Ann. Physik, 1936, [v], 25, 512—526; cf. A., 1935, 1306).—The directions of reflexion from a crystal for a given  $\lambda$  can be represented by the intersections with the surface of a sphere of a series of planes corresponding with the lattice planes. The development of such a system of reflexions with decreasing  $\lambda$  for a face-centred cubic lattice is illustrated.

L. J. J.

**Theoretical and experimental Laue patterns from bent sodium chloride crystals.** A. P. KOMAR (Nature, 1936, 137, 397—398).—A method of calculation and construction of Laue patterns from bent crystals of NaCl which gives good agreement with experimental patterns is proposed. The agreement shows that in the process of plastic deformation the crystal behaves as a mosaic aggregate of blocks which change their orientation practically independently.

L. S. T.

**Stability of closest packing of spheres.** R. NIINI (Ann. Acad. Sci. fenn., 1934, 39, A, No. 10; Chem. Zentr., 1935, ii, 13).—The hexagonal close-packed arrangement has the smallest potential energy.

J. S. A.

**Transition mechanism of cubic body-centred into hexagonal close-packed zirconium. Relation with the modifications of calcium.** W. G. BURGERS (Metallwirts., 1934, 13, 785—786; Chem. Zentr., 1935, ii, 318).—A cubic face-centred intermediate phase is assumed, but has not been detected. For Ca all three forms are known.

H. J. E.

**Kinetics of recrystallisation of tin, cadmium, and iron.** M. KORNFELD and F. SAVIZKI (Physikal. Z. Sovietunion, 1935, 8, 528—532).—In the recrystallisation of these metals, as with Al (Karnop, A., 1930, 530; B., 1930, 911) and rock-salt (Müller, A., 1934, 1058), there is an incubation period before the appearance of cryst. nuclei. The rate of growth of crystals is linear with time. Recovery from deformation is complete before the appearance of the first visible nucleus.

A. J. M.

**Formation of nuclei in recrystallisation. II. Nature of the incubation period.** M. KORNFELD (Physikal. Z. Sovietunion, 1935, 8, 533—535; cf. A., 1935, 1307).—The existence of the incubation period can be explained in two ways: (1) the formation of a

nucleus in a small vol. of the deformed material takes place suddenly owing to a single thermal fluctuation, and (2) a continuous irreversible process takes place in a definite part of the deformed material from the commencement of heating. The incubation period corresponds with the time taken for the completion of this process. The dependence of the no. of recrystallisation nuclei on the duration of heating is calc. on the basis of each of these explanations. The results of experiment favour the second explanation.

A. J. M.

**Effect of heat-treatment on the structure of gold- and silver-leaf.** G. D. PRESTON and L. L. BIRUMSHAW (Phil. Mag., 1935, [vii], 21, 713—727).—The contraction when Au-leaf is heated in air at 350—400° was shown by electron diffraction to be due to recrystallisation and reorientation. The new grains grow in a position favourable for reflexion from the (110) planes. The effect may be connected with transitory oxide formation, since it does not occur in H<sub>2</sub> or in vac. up to 700°. Similar, though less definite, results were obtained for Ag heated in air at 290°. Certain "extra" rings were attributed to the presence of Hg, but do not correspond with known phases in the Au-Hg and Ag-Hg systems. Phases present in thin films may have a different structure from those in the massive state.

H. J. E.

**Structure of solid  $\gamma$ -oxygen.** W. H. KEESOM and K. W. TACONIS (Physica, 1936, 3, 141—144).—Results obtained by the X-ray goniometer are identical with those of Vegard (cf. A., 1935, 1450).

N. M. B.

**Theoretical diffraction patterns corresponding with some simple types of molecular arrangement in liquids.** J. A. PRINS and H. PETERSEN (Physica, 1936, 3, 147—153).—Computations are made for the structures: (a) cubic and hexagonal close-packed, (b) body-centred cubic, (c) simple cubic, (e) diamond structure; the respective co-ordination numbers are 12, 8, 6, and 4. Results are confirmed experimentally by taking for (a) inert gases and Hg, (b) alkali metals, (c) Sb, (d) SiO<sub>2</sub> and H<sub>2</sub>O.

N. M. B.

**Structure of stannous sulphide and teallite.** W. HOFMANN (Fortschr. Min., 1935, 19, 30—31; Chem. Zentr., 1935, ii, 820).—Herzenbergite SnS (I), teallite PbSnS<sub>2</sub> (II), and synthetic ZnS have very similar deformed galena structures. (I) and (II) have  $a$  3.98, 4.04,  $b$  4.33, 4.28,  $c$  11.18, 11.33 Å., respectively.

J. S. A.

**X-Ray study of anhydrous ferric phosphates.** P. BRASSEUR (Compt. rend., 1936, 202, 761—762).—X-Ray diagrams showed the existence of only two forms of the metaphosphate Fe<sub>3</sub>(PO<sub>3</sub>)<sub>6</sub>. Characteristic diagrams were obtained from Fe<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub> and from a pyrophosphate Fe<sub>3</sub>(P<sub>2</sub>O<sub>7</sub>)<sub>3</sub>. No characteristic diagram was observed for Fe<sub>3</sub>O<sub>3</sub>(P<sub>2</sub>O<sub>5</sub>)<sub>2</sub>. An impure basic phosphate was identified.

H. J. E.

**Interpretation of X-ray diffraction pattern of liquid carbon tetrachloride.** I. NITTA and T. WATANABÉ (Sci. Papers Inst. Phys. Chem. Res. Tokyo, 1936, 28, 277—283).—It is inferred that under the influence of the van der Waals forces adjacent mols. orient themselves preferentially with

tetrahedral faces towards one another, giving a quasi-association. The distance between the centres of Cl atoms of adjacent mols. is 3.90 Å., i.e., the "envelope" around a Cl atom is 0.98 Å. thick.

R. S. B.

**Structure of cellulose nitrates.** I. Normal high nitrates. II. X-Ray patterns and structure of nitrates of various nitrogen contents. III. Density of nitrates and the properties of the recovered cellulose. IV. Existence of various space lattices of nitrates of the same nitrogen content. M. ISHIHARA (J. Soc. Chem. Ind. Japan, 1936, 39, 62—65B, 65—68B, 68—70B, 70—74B).—I. Details are given of the X-ray pattern of nitrated hemp (13.3% N); it is concluded that the lattice unit contains 20 glucopyranose nitrate units in four chains each five units long. No period corresponding with two units was observed.

II. The X-ray patterns of nitrates containing 3.95—13.54% N are described, and differences are observed between the classes 0—7, 10.01, 10.87, 12.80—13.2, 13.3—13.5, and 13.5% N.

III. Measurements of  $d$  of cellulose nitrates in H<sub>2</sub>O show that, with some exceptions,  $d$  increases with increasing N content, but not linearly.

IV. Nitrates with approx. the same N content (>13%) have different X-ray diagrams, and hence different lattices, according to their mode of prep. or subsequent treatment.

A. G.

**$\beta$ -Modification of the gutta-percha hydrocarbon.** G. W. PANKOW (Helv. Chim. Acta, 1936, 19, 221—222).—The stretched  $\beta$ -hydrocarbon shows interference in the X-ray diagram corresponding to a unit of length about 115 Å. along the length of the fibre.

R. S. C.

**X-Ray study of amorphous rubber.** G. L. SIMARD and B. E. WARREN (J. Amer. Chem. Soc., 1936, 58, 507—509).—The X-ray scattering curve for unstretched rubber has been submitted to a Fourier analysis. The distribution agrees with the view of a long-chain mol.

E. S. H.

**Electron microscope for filaments: emission and adsorption by tungsten single crystals.** R. P. JOHNSON and W. SHOCKLEY (Physical Rev., 1936, [ii], 49, 436—440).—A simple electron microscope for small cylindrical filaments is described. The activation of thoriated W was investigated. Electron emission from single crystals grown in drawn pure W filaments varies around the wire circumference and depends on crystallographic direction; the variation with this is more pronounced and complex for filaments self-activated in Cs or K vapour.

N. M. B.

**Surface structure of polished cleavage faces of calcite.** H. G. HOPKINS (Phil. Mag., 1936, [vii], 21, 820—830).—The polished cleavage face of calcite was shown, by electron diffraction, to be crystal. The action of very dil. acids is essentially one of pitting. Kikuchi lines were observed at a depth of 200 Å. The polishing action extends to a depth of 6000 Å., as a twinned layer was observed at this depth.

H. J. E.

**Experiments with models on the theory of the Kikuchi lines.** A. LICHTENFELD and K. SCHWARZ (Naturwiss., 1936, 24, 172—173).—The  $\lambda$  of electrons used in investigation of crystal structure is about 100 times  $<$  the distance between the lattice planes. It is suggested that besides diffraction phenomena, purely optical processes, such as shadow formation, will be encountered, and that the latter gives rise to the Kikuchi lines. Models of the NaCl lattice, with the lattice const. about 1000 times  $>$   $\lambda$  of visible light, give shadow effects with such light similar to the Kikuchi lines. A. J. M.

**Experiments with models on the theory of the Kikuchi lines.** M. VON LAUE (Naturwiss., 1936, 24, 218).—The model suggested by Lichtenfeld *et al.* (see above) for explaining the Kikuchi lines as a shadow effect is criticised on the ground that the shadows appear to be cast by the rods joining the spheres representing atoms in the model, instead of by the spheres themselves, and that the shadows fall in the direction of the incident light, whereas the position of the Kikuchi lines is determined only by the lattice. A. J. M.

**Theory of Kikuchi lines.** M. VON LAUE (Ann. Physik, 1936, [v], 25, 569—576; cf. A., 1935, 1306). L. J. J.

**Examination by electron beams of some aliphatic esters.** G. NATTA and R. RIGAMONTI (Atti R. Accad. Lincei, 1935, [vi], 22, 342—348).—Investigation of thin films of some aliphatic long-chain compounds (fatty acids, ethers, esters, and ketones) by means of electron diffraction shows that they all give two fundamental distances lying in the plane of the film and normal to the chain axis, viz., 7.46 and 4.98 Å. These are found also in the paraffins. It is suggested that these long-chain compounds show a two-dimensional isomorphism, which is independent of the active terminal groups and persists when  $\cdot\text{CH}_2\cdot$  groups are replaced at long intervals by  $\cdot\text{CO}\cdot$  or  $\cdot\text{O}\cdot$ . O. J. W.

**Supposed dependence on temperature of spontaneous magnetisation.** K. HONDA and T. NISHINA (Z. Physik, 1936, 98, 657—665).—Variation of remanent magnetisation with temp. has been measured for the three principal axes of single Fe crystals, and shows no dependence on temp. of spontaneous magnetisation. A. B. D. C.

**Volta potential, work function, and thermopotential.** I. G. MÖNCH (Erlanger Ber., 1934, 65, 191—201; Chem. Zentr., 1935, ii, 20).—A survey of the author's results as to (i) the relation between the Volta potential and the work function; (ii) the variation of the Volta potential of metals with temp. (no measurable variation up to 400°); (iii) the variation with temp. of the Volta potential of semiconductors.  $\text{Cu}_2\text{O}$  becomes more negative at high temp., probably due to alteration in the Volta potential; (iv) the connexion between Volta potential and thermopotential; (v) relationships between Volta potential, lattice dimensions, and at. vol. J. S. A.

**Connexion between work function and Volta potential.** II. G. MÖNCH (Erlanger Ber., 1934,

65, 202—207; Chem. Zentr., 1935, ii, 20).—For the metal pair W—Pt, the difference between the work functions is equal in magnitude to the difference in Volta potentials. J. S. A.

**Dependence of Volta potential on state of strain of a metal surface.** VI. G. MÖNCH (Erlanger Ber., 1934, 65, 211—214; Chem. Zentr., 1935, ii, 21).—The work function of a Ni surface, measured by the Volta potential, was not changed by the surface strains and lattice distortion resulting from flexion below the elastic limit. With  $\text{Cu}_2\text{O}$  a reproducible change occurred. J. S. A.

**Internal energy of ferromagnetics.** E. C. STONER (Phil. Trans., 1936, A, 235, 165—193).—Theoretical. A crit. analysis of the results obtained for the magnetisation, magneto-caloric effect, and sp. heat of Ni by various experimental methods is given. Discrepancies in  $-(1/\sigma)(dE/d\sigma)$  ( $E$ =internal energy,  $\sigma$ =sp. magnetisation) derived by different methods can be explained by supposing that a small amount of the Ni consists of domains of  $10^3$ — $10^4$  atoms. It is suggested that such domain-structure is not confined to ferromagnetics, but is practically equiv. to the mosaic structure met with in metals in general, due to distortion arising from impurity atoms. A. J. M.

**Refraction and dispersion in crystals and solids.** XII. Molecular refractivities and molecular volumes in the glasses  $\text{B}_2\text{O}_3$ ,  $\text{B}_2\text{O}_3, x\text{Na}_2\text{O}$ , and  $\text{B}_2\text{O}_3, x\text{Na}_2\text{O}, y\text{NaCl}$ . P. WULFF and S. K. MAJUMDAR (Z. physikal. Chem., 1936, B, 31, 319—342).—The  $d$  of anhyd.  $\text{B}_2\text{O}_3$  is  $<$  that of  $\text{B}_2\text{O}_3$  containing a small amount of  $\text{H}_2\text{O}$ , whilst the mol. refractivity,  $R$ , is larger; apparently  $d$  passes through a max. at a very small  $\text{H}_2\text{O}$  content. The apparent mol. vol.,  $\Phi$ , and  $R$  of  $\text{Na}_2\text{O}$  in  $\text{Na}_2\text{O}$ — $\text{B}_2\text{O}_3$  glass rise with the  $\text{Na}_2\text{O}$  content, but approach a limit at  $\text{Na}_2\text{O}:\text{B}_2\text{O}_3=1:2$ . For  $\text{B}_2\text{O}_3$   $\Phi$  is approx. const. in presence of varying amounts of  $\text{Na}_2\text{B}_4\text{O}_7$ , but is  $<$  the val. for pure  $\text{B}_2\text{O}_3$  glass. For  $\text{Na}_2\text{B}_4\text{O}_7$   $R$  and  $\Phi$  fall with increase in the ratio  $\text{B}_2\text{O}_3:\text{Na}_2\text{B}_4\text{O}_7$ , the effect being large compared with those observed with aq. solutions. These variations are ascribed to the effect of the  $\text{Na}^+$  ions and dipole mols. on the  $\text{B}_2\text{O}_3$  glass, acting as solvent of small dielectric const. The  $R$  and  $\Phi$  of NaCl dissolved in  $\text{Na}_2\text{O}$ — $\text{B}_2\text{O}_3$  glass are rather  $<$  those of cryst. NaCl, corresponding with the view that a one-sided deformation of ions in the formation of mols. has a greater effect on refractivity than a deformation on all sides, as in a crystal lattice. R. C.

**[Optical] dispersion of crystalline and vitreous quartz.** J. ENGL (Ann. Physik, 1936, [v], 25, 600—608).—Theoretical. A formula is given for the refractive power of  $\text{SiO}_2$  as a function of  $\lambda$ . The relation between the dispersive power and the absorption coeff. with varying  $\lambda$  is discussed. L. J. J.

**Theory of elastic after-effect in un-ordered mixed crystals.** V. S. GORSKI (Physikal. Z. Sovietunion, 1935, 8, 457—471).—Mathematical. The after-effect in polycryst. metals and alloys is discussed in relation to diffusion and a theory is developed. W. R. A.

**Metallic crystals.** E. SCHMID (Rev. Mét., 1935, 32, 638—648).—A survey is given of the properties of single crystals in which attention is given to lattice types and the mechanism of transformation from type to type. Properties discussed are anisotropy of physical properties, mode of plastic deformation, pptn. from supersaturated solid solution, and the relationship between the polycryst. aggregates and single crystals. E. H. B.

**Electrical and optical investigations of the conversion of non-metallic into metallic antimony.** R. SUHRMANN and W. BERNDT (Physikal. Z., 1936, 37, 146—149).—Sb vapour was condensed in vac. on a quartz surface cooled by liquid  $N_2$ , and the absorption spectrum of the substance immediately after condensation compared with that shown by the film after it had warmed to a temp.  $>$  transition temp. at which the film becomes metallic in character. Well-defined absorption lines were found at low temp. but they disappeared on warming to  $373^\circ$  abs., indicating a transition from the non-metallic to the metallic state. The transition temp. varied with the thickness of the film, three vals. obtained being  $325^\circ$  (15  $m\mu$ ),  $280^\circ$  (35  $m\mu$ ), and  $270^\circ$  abs. (109  $m\mu$ ). The higher val. obtained by Kramer *et al.* (A., 1932, 1192) is possibly due to the film containing gas. A. J. M.

[Allotropy of] potassium metaphosphate prepared by dehydration of potassium dihydrogen orthophosphate. A. BOULLÉ (Compt. rend., 1936, 202, 662—664).—Thermal analysis of  $KPO_3$  obtained by dehydration of  $KH_2PO_4$  at  $225^\circ$  indicates reversible transformations at  $460^\circ$  and  $650^\circ$ . The X-ray spectrum and the m.p. ( $810^\circ$ ) are unaffected by washing the product. The same X-ray spectrum is given by the initial dehydration product, the product of slow cooling from fusion, and specimens cooled rapidly from  $300^\circ$ ,  $550^\circ$ ,  $615^\circ$ ,  $700^\circ$ , and  $800^\circ$ , which give different viscosities in 0.1N- $Na_4P_2O_7$  solution. It is concluded that only the amorphous form and a single cryst. form can exist at room temp. L. J. J.

**Transition of solid ammonium bromide at about  $-39^\circ$ .** A. SMITS, J. A. A. KETELAAR, and G. J. MÜLLER (Z. physikal. Chem., 1936, 175, 359—376).—The results of the study of the transition of  $NH_4Cl$  (A., 1933, 1119) are examined thermodynamically in relation to Smits' theory of allotropy. Dilatometric studies have shown that at about  $-39^\circ$   $NH_4Br$  undergoes a heterogeneous transition, arising from a homogeneous transformation above or below the transition region. There is a region of heterogeneous hysteresis extending over  $0.06^\circ$ . It is suggested that one pseudo-component of the system  $NH_4Br$  contains oscillating, the other rotating,  $NH_4$  groups. R. C.

**Sodium benzyldisulphonate: dimorphism.** F. D. DODGE (J. Amer. Chem. Soc., 1936, 58, 437—438).—The conditions of formation of an unstable orthorhombic and a stable mono- (or tri-)clinic modification are described. Peculiar optical properties of the latter form may be due to twinning of the crystals. E. S. H.

**Dispersion of sound and stereochemistry of nitrogen atom.** O. STEEL (Z. physikal. Chem., 1936, B, 31, 343—360).—By means of an acoustic interferometer capable of measurements up to  $150^\circ$  the velocity of sound,  $v$ , in  $NH_3$  at room temp. has been measured. Between 300 and 1000 kilohertz there is anomalous dispersion of  $v$ , which is probably connected with the N atom moving through the  $H_3$  plane so as to turn the pyramidal mol. inside out. A relation between  $v$  and frequency is deduced. R. C.

**Velocity of ultrasonic waves at low pressures.** E. J. PUMPER (Physikal. Z. Sovietunion, 1935, 8, 300—310).—The influence of pressure on the velocity of ultrasonic waves in air and in  $CO_2$  at low pressures has been studied, and the reasons for the observed deviations from classical laws are discussed. R. S.

**Absorption of ultrasonic waves in certain liquids.** P. BASHULIN (Physikal. Z. Sovietunion, 1935, 8, 354—358).—The absorption coeffs.  $\alpha$  of ultrasonic waves in vaseline-petroleum mixtures and in  $CCl_4$  have been determined by two methods depending on the diffraction of light. Agreement with the hydrodynamic theory is only partial.  $\alpha$  is unaffected by rise of temp. R. S.

**Diffraction of light by high-frequency sound waves. III. Doppler effect and coherence phenomena.** C. V. RAMAN and N. S. N. NATH (Proc. Indian Acad. Sci., 1936, 3, A, 75—84; cf. this vol., 148).—Theoretical. The variation of the refractive index of the medium with time is taken into account. L. J. J.

**Diffraction of light by high-frequency sound waves. IV. Generalised theory.** C. V. RAMAN and N. S. N. NATH (Proc. Indian Acad. Sci., 1936, 3, A, 119—125).—Mathematical. O. D. S.

**Theory of volume anomalies for ferromagnetic substances.** L. NÉEL (Compt. rend., 1936, 202, 742—744).—Theoretical. H. J. E.

**Magnetic atomic moments of manganese dissolved in copper, silver, and gold.** G. GUSTAFSSON (Ann. Physik, 1936, [v], 25, 545—560).—A method of measuring para- and dia-magnetic susceptibilities of samples in the form of wire at  $20$ — $450^\circ$  is described. Data are recorded for the at. susceptibility ( $\chi_A$ ) and at. moment of Mn for a no. of dil. solid solutions in Cu, Ag, and Au. There is a linear relation between  $\chi_A$  and  $1/T$ . L. J. J.

**Magnetic susceptibility of single crystals of lead, thallium, and tin.** S. R. RAO and K. R. SUBRAMANIAM (Phil. Mag., 1936, [vii], 21, 609—624).—No change in the magnetic susceptibility ( $\chi$ ) of single Pb or Sn crystals is noted as they are rotated about the cylindrical axis. For  $\alpha$ -Tl,  $\chi$  parallel to and perpendicular to the hexagonal axis is  $0.412$  and  $0.165 (\times 10^{-6})$ , respectively, indicating a magnetic anisotropy ( $2.5$ )  $>$  for other similar metals. The average val. for polycryst.  $\alpha$ -Tl is  $0.247$ . The mean val. of  $\chi$  for  $\beta$ -Tl (cubic) is  $0.158 \times 10^{-6}$ , becoming  $0.131 \times 10^{-6}$  after melting. It is suggested that two of the three valency electrons in  $\alpha$ -Tl have orbits in the hexagonal planes and that their linking is

homopolar, whilst the third electron is free. In  $\beta$ -Ti there are probably only Ti<sup>+</sup> ions, with the remaining electron free. J. W. S.

**Magnetochemical investigations. XX. Magnetic behaviour of simple vanadium compounds.** W. KLEMM and E. HOSCHKE (Z. anorg. chem., 1936, 226, 359—369).—The magnetic susceptibilities ( $\chi$ ) of V<sub>2</sub>O<sub>5</sub>, VCl<sub>4</sub>, VO<sub>2</sub>, VCl<sub>3</sub>, VBr<sub>3</sub>, V<sub>2</sub>O<sub>3</sub>, V<sub>2</sub>S<sub>3</sub>, VCl<sub>2</sub>, and VBr<sub>2</sub> have been measured at 20°, -78°, and -183°.  $\chi$  for VCl<sub>4</sub>, VCl<sub>3</sub>, and VBr<sub>3</sub> is in accord with theory, but for VCl<sub>2</sub> and VBr<sub>2</sub> divergencies are obtained, especially at low temp.  $\chi$  for V<sub>2</sub>O<sub>5</sub> is in accord with theory; VO<sub>2</sub> in spite of its odd no. of electrons is almost non-magnetic. V<sub>2</sub>O<sub>3</sub> and V<sub>2</sub>S<sub>3</sub> show deviations from the vals. expected for ionic compounds, of the magnitude observed with other analogous compounds. V<sub>2</sub>S<sub>5</sub> does not exist, and heating of V<sub>2</sub>S<sub>3</sub> with S yields only a polysulphide of composition between VS<sub>3.8</sub> and VS<sub>4</sub>. J. W. S.

**New types of complex paramagnetic salts of the iron series.** L. CAMBI and A. CAGNASSO (R. Ist. lomb. Sci. Lett., 1934, [ii], 67, 741—747; Chem. Zentr., 1935, ii, 331; cf. A., 1934, 1057).—The vals. of  $\chi$  for complex salts of Fe(CNS)<sub>2</sub> and Co(CN)<sub>2</sub> with *o*-phenanthroline and 2:2'-dipyridyl point to the existence of forms derived from the homopolar valency 3d4sp<sup>2</sup>, as predicted by Pauling (A., 1931, 670, 1356). H. J. E.

**Determination of magnetic susceptibilities of some diamagnetic compounds. Calculation of ionic susceptibilities.** O. E. FRIVOLD (Avh. norsk. Vidensk.-Akad. Oslo, Mat.-nat. Kl., 1933, No. 9, 21 pp.; Chem. Zentr., 1935, ii, 331).—The vals. for  $\chi_m \times 10^6$  in aq. solution at 20° were: HCl 21.0, HBr 32.5, LiCl 24.2, LiBr 36.0, KBr 50.3, KF 24.1, CaCl<sub>2</sub> 56.7, CaBr<sub>2</sub> 78.5, SrCl<sub>2</sub> 65.3, SrBr<sub>2</sub> 87.9, BaCl<sub>2</sub> 76.3, CdBr<sub>2</sub> 92.1, K<sub>4</sub>Fe(CN)<sub>6</sub> 134.1, ZnCl<sub>2</sub> 60.1. Vals. of the ionic  $\chi$  were calc. H. J. E.

**Measurement of the coefficient of magnetisation of organic liquids.** C. COURTY (Bull. Soc. chim., 1936, [v], 3, 420—422).—The mol. susceptibilities of pyrrole and nicotine are  $46.029 \times 10^{-6}$  and  $116.316 \times 10^{-6}$ , respectively. E. S. H.

**Thermomagnetism of rare earth salts in solution.** G. DUPOUX (Compt. rend., 1936, 202, 646—648).—Data are recorded for the paramagnetic ions Pr<sup>+++</sup>, Nd<sup>+++</sup>, Sm<sup>+++</sup>, Eu<sup>+++</sup>, and Gd<sup>+++</sup>, for which the magnetic moment and Curie temp. are calc. Weiss' law is obeyed by all the solutions studied. The existence of different magnetic states is indicated. L. J. J.

**Magnetic effects and current-sensitivity of superconducting films.** A. D. MISENER (Canad. J. Res., 1936, 14, A, 25—37).—The extent to which an external magnetic field will penetrate a thin superconducting film of Sn, mounted on a German-silver tube, has been studied for films of various thicknesses (12.2—0.3  $\mu$ ) at different temp. < transition point. There is a crit. field which will penetrate the film, this field being < that required to restore the resistance of the film at the same temp. The current-sensitivity of the films is due to a surface increase of c.d. The restoration of resistance is caused by the

magnetic field associated with the current, but this field is < that which has to be applied externally to produce the same result. Thin films of Sn are anomalous superconductors. A. J. M.

**Superconductive tantalum.** K. MENDELSSOHN and (Miss) J. R. MOORE (Phil. Mag., 1936, [vii], 21, 532—544).—A discrepancy exists between the magnetic threshold curve and the penetration curve for superconducting Ta, similar to that observed for alloys (A., 1934, 480; 1935, 20). This is attributed to the formation of a non-homogeneous sponge-like structure, since thermodynamically if the same free energy difference occurs between superconductive and normal Ta, much higher magnetic threshold vals. would be expected for small regions than for solid material. J. W. S.

**Relaxation phenomena in the transition from the superconductive to the non-superconductive state.** W. H. KEESOM and P. H. VAN LAER (Physica, 1936, 3, 173—181).—The transition in the case of Sn, if caused by a rise of temp. with const. magnetic field, takes place with a relaxation of several sec.; if caused by an increase of external magnetic field no appreciable relaxation is found. These results agree with the view that, the threshold val. curve being reached, there is a weak coupling between the at. lattice and the system of superconductive electrons, and a strong coupling between the latter and the external magnetic field and between the non-superconductive electrons and the at. lattice. N. M. B.

**Transition of a monocrystalline tin sphere from the superconductive to the non-superconductive state.** W. J. DE HAAS and O. A. GUINAU (Physica, 1936, 3, 182—192).—Transition is investigated at const. temp. with increasing magnetic field and at const. external field and rising temp. Relations between permeability, applied field, and crit. field are determined. N. M. B.

**Energetic theory of thermo-electric phenomena.** F. MICHAUD (J. Chim. phys., 1936, 33, 161—179).—The classical theory is criticised. It is shown that thermo-electric phenomena are partly irreversible in nature, and an appropriate equation has been deduced. R. S.

**Thermo-electric and voltaic properties of normal and abnormal metallic films.** R. DEAGLIO (Compt. rend., 1936, 202, 831—832).—The electrical properties of Au films vary with variation in colour by transmitted light. An e.m.f. of 0.6 volt may be obtained from the system: red or blue Au film|H<sub>2</sub>O|massive Au, but, after replacement of the red by a green film, the voltage is < 0.005. By combining the green film with massive Au in a hot and cold junction, however, a definite e.m.f. is obtained. The results may be explained by Perucca's theory (A., 1930, 280) of a difference between the surface and bulk concn. of electrons in a metal. In the first case the surface concn. is involved and in the second the bulk concn. M. S. B.

**Atomic heats and heats of fusion of neon, argon, and krypton.** K. CLUSIUS (Z. physikal. Chem., 1936, B, 31, 459—474).—The at. heats have been determined between 10° abs. and the normal

b.p. The Debye  $\theta$  vals. and latent heats of fusion are: Ne, 64°, 80.1; A, 80°, 280.8; Kr, 63°, 390.7 g.-cal. per mol.; Xe, 55°. For A, Kr, and Xe the observed  $\theta$  vals. agree with those calc. from Lindemann's formula with a modified numerical factor:  $0 = 163 \sqrt{(T_e/A v^{2/3})}$  ( $T_e = \text{m.p.}$ ,  $A = \text{at. wt.}$ ). The calc. (approx.) compressibilities and the relative space demands of the individual atoms in the solid decrease with increasing at. wt. With He the zero point energy has a decisive influence on the thermal behaviour, and with Ne the effect is still appreciable, but from A onwards it is negligible. In applying the principle of corresponding states to the thermal data the zero point energy must be allowed for. R. C.

**Specific heats of liquid carbon tetrachloride at high temperatures.** G. DAMKÖHLER (Z. physikal. Chem., 1936, B, 31, 439—453).—The isentropic cooling on adiabatic expansion, the coeff. of expansion, and the isothermal compressibilities have been determined at room temp. to 200°, and from them  $C_p$  and  $C_v$  under 26 atm. calc. The difference between  $C_p$  and that part of it due to at. vibrations within the mol. is const. at 10.4 g.-cal. up to 100°, then slowly rises with the temp. and approaches  $6R$ . It is inferred that the rotation of the mols. in the liquid is not completely free, neither is there pure rotation-vibration. R. C.

**Determination of molecular heat of gases at low temperatures by thermal conductivity method.** A. EUCKEN and A. BERTRAM (Z. physikal. Chem., 1936, B, 31, 361—381).—The method previously described (A., 1934, 20) has been developed further and used to determine the mol. heat of Kr, N<sub>2</sub>, CO, CH<sub>4</sub>, C<sub>2</sub>H<sub>4</sub>, C<sub>2</sub>H<sub>6</sub>, SF<sub>6</sub>, SeF<sub>6</sub>, TeF<sub>6</sub>, CF<sub>2</sub>Cl<sub>2</sub>, C<sub>2</sub>H<sub>2</sub>, C<sub>2</sub>N<sub>2</sub>, and CF<sub>4</sub> at 150—280° abs. From the results the following fundamental frequencies have been deduced: CF<sub>2</sub>Cl<sub>2</sub>,  $\nu_{\text{rotation}} = 408$ ; C<sub>2</sub>N<sub>2</sub>,  $\delta(a) = 740$ ; CF<sub>4</sub>,  $\nu_3 = 503$ ,  $\nu_4 = 1000$  ( $\pm 100$ ) cm.<sup>-1</sup>. At temp. equal to about  $\frac{3}{2}T_b$ , where  $T_b$  is the b.p. abs., the accommodation coeffs. of the above gases and A on an oxidised Ni wire in respect of translational degrees of freedom are  $\sim 1$ . For the variation with temp.,  $T$ , of the accommodation coeff. in respect of rotational and vibrational degrees of freedom,  $\alpha'$ , the equation  $\log_e (1/\alpha' - 1) = -A/T + B$  has been deduced theoretically and agrees with the experimental data. In general,  $A$  increases with  $T_b$ . R. C.

**Thermal data on organic compounds. XVI.** Heat capacity, entropy, and free energy data for typical benzene derivatives and heterocyclic compounds. G. S. PARKS, S. S. TODD, and W. A. MOORE (J. Amer. Chem. Soc., 1936, 58, 398—401; cf. this vol., 278).—Data for C<sub>6</sub>H<sub>3</sub>Ph<sub>3</sub>, PhNO<sub>2</sub>, PhSH, CH<sub>2</sub>Ph.OH, *o*-C<sub>6</sub>H<sub>4</sub>(CO<sub>2</sub>H)<sub>2</sub>, *o*-C<sub>6</sub>H<sub>4</sub>(CO)<sub>2</sub>O, C<sub>5</sub>H<sub>5</sub>N, and quinoline are recorded. E. S. H.

[Boiling points of elements.] J. J. VAN LAAR (Chem. Weekblad, 1936, 33, 215—216).—A criticism. The following b.p. are recorded: Zn 907°, Cd 767°, Hg 356.71°, Sc 2400°, Cu 2369°, Pb 1730°. S. C.

**Critical temperatures of simple deuterium compounds.** H. KOPFER (Z. physikal. Chem., 1936, 175, 469—472).—The crit. temp. for various D

compounds have been determined. They are  $<$  those of the corresponding H compounds. R. C.

**Fusion.** E. L. HILL (Physical Rev., 1936, [ii], 49, 406).—A discussion of Herzfeld's theory of the fusion of solid A and He (cf. A., 1935, 157).

N. M. B.

**X-Ray measurement of the thermal expansion of pure nickel.** E. A. OWEN and E. L. YATES (Phil. Mag., 1936, [vii], 21, 809—819).—The parameter of Ni at 18° was 3.5172<sub>4</sub> Å. Its structure was face-centred cubic (12—600°). In the region of magnetic transformation (320—390°) there was an abnormally high rate of expansion (max. at 370°), followed by a rapid decrease. The ferromagnetic change in length per unit length for 99.98% pure Ni was  $2.4 \times 10^{-4}$ .

H. J. E.

**Vapour density of water.** R. SCHARF (Z. phys. chem. Unter., 1935, 48, 108—110; Chem. Zentr., 1935, ii, 87).—A modification of the Victor Meyer method is described, using apparatus filled with H<sub>2</sub>.

J. S. A.

**Temperature dependence of the vapour pressure of metals.** W. LEITGEBEL (Metallwirts., 1935, 14, 267—270; Chem. Zentr., 1935, ii, 334).—A summary and crit. discussion of available data.

H. J. E.

**Vapour pressure of caesium.** J. A. M. VAN LIEMPT (Rec. trav. chim., 1936, 55, 157—160).—Formulæ for the v.p. of liquid and solid Cs, based on the most accurate published data, are given.

F. L. U.

**Vapour pressure abnormalities of capillary-active amalgams.** H. H. VON HALBAN (Helv. phys. Acta, 1935, 8, 65—79; Chem. Zentr., 1935, ii, 334).—Na, K, and Zn amalgams have abnormally low Hg v.p. unless the surface is fresh. The hypothesis of surface enrichment of the dissolved metal is not entirely satisfactory. An adsorbed film of C<sub>6</sub>H<sub>6</sub> does not alter the v.p. of Hg.

H. J. E.

**Methods and apparatus in use at the Bureau des Etalons Physico-Chimiques. IX.** Variation of the density as a function of temperature for a series of ten hydrocarbons. L. MASSART (Bull. Soc. chim. Belg., 1936, 45, 76—94).—Liquid and v.d. of C<sub>6</sub>H<sub>6</sub>, PhMe, *o*-, *m*-, and *p*-xylene, PhEt, PhPr<sup>2</sup>, PhBu<sup>2</sup>, cyclohexane, and methylcyclohexane have been determined dilatometrically from the m.p. to  $>$  b.p.

R. S.

**Vapour pressures and association of metallic and non-metallic alkyls.** H. W. THOMPSON and J. W. LINNETT (Trans. Faraday Soc., 1936, 32, 681—685).—V.p. of the following have been measured: ZnMe<sub>2</sub>, ZnEt<sub>2</sub>, HgMe<sub>2</sub>, HgEt<sub>2</sub>, SnMe<sub>4</sub>, PEt<sub>3</sub>, NMe<sub>3</sub>, NEt<sub>3</sub>, MeI. The Trouton consts. are calc., and indicate little or no association. The results are compared with those for other similar compounds.

F. L. U.

**Formation of drops in supersaturated D<sub>2</sub>O vapour.** Surface tension of D<sub>2</sub>O. H. FLOOD and L. TRONSTAD (Z. physikal. Chem., 1936, 175, 347—352).—The adiabatic expansion required for drop formation in D<sub>2</sub>O vapour is  $\ll$  than that necessary with H<sub>2</sub>O. This is explained on Volmer's theory (A., 1935, 25) by the variation of the metastable limit with temp.

The difference in the crit. supersaturations, however, is small, because the supersaturation of  $D_2O$  increases with the degree of supercooling more rapidly than that of  $H_2O$ . At 12–50° the surface tension of 99%  $D_2O$  is the same as that of  $H_2O$  (cf. *ibid.*, 1059). R. C.

**Application of kinetic theory to the problems of evaporation and sublimation of monatomic gases.** P. D. CROUT (J. Math. Phys. Mass. Inst. Tech., 1936, 15, 1–54).—The complete relationship between surface pressure and rate of evaporation for all rates of evaporation is derived. At the boundary of the liquid surface where isotropy has not been attained, it is necessary to assume two temp. corresponding with mol. motions parallel and normal to the liquid surface. It is assumed that velocity distribution of the emitted mols. is unaffected by that of the incident mols. It follows that the rate of evaporation cannot exceed that corresponding with a drift velocity equal to the velocity of sound in the isotropic gas. The anisotropic region has a depth of the order of several mean free paths. The theory is illustrated by data on the evaporation of Hg. C. R. H.

**Theoretically interesting aspects of high-pressure phenomena.** P. W. BRIDGMAN (Rev. Modern Phys., 1935, 7, 1–33). CH. ABS. (e)

**Extreme values of the Joule-Thompson effect. Inversion points of the second order.** V. JACZYNA (Z. Physik, 1936, 98, 775–789).—Theoretical.

A. B. D. C.

**Glass. XIV. Compressibility of glucose glass.** J. C. LYMAN and G. S. PARKS (J. Chem. Physics, 1936, 4, 218–219).—The coeff. of cubic compressibility of glucose glass (I) at 24° is  $18.8 \times 10^{-4}$  atm.<sup>-1</sup> at 7–25 atm. Liquid glycerol and (I) have a smaller compressibility and thermal expansion than org. substances such as EtOH and  $C_6H_6$  (liquid and cryst.), indicating that the intermol. forces in polyhydroxy-compounds are considerably > in ordinary liquids, or even in a typical non-polar crystal. This is probably a factor governing the formation of a stable glass. M. S. B.

**Gas-kinetics properties of light and heavy hydrogen.** O. HALPERN and E. GWATHMEY (J. Chem. Physics, 1936, 4, 229).—The effect of statistical wts. of mols. on the difference between the viscosity of ordinary and para-H at different temp. has been calc. The difference is thus shown to be vanishingly small for D. M. S. B.

**Viscosity of "ice sol" as dependent on temperature and concentration.** E. EMBLIK (Z. ges. Kalte-Ind., 1935, 42, 71–74; Chem. Zentr., 1935, ii, 23).—Data for the dynamic and kinematic viscosity are given. J. S. A.

**Viscosity of methyl alcohol and acetone above their b.p.** P. C. BLOKKER (Rec. trav. chim., 1936, 55, 170–172; cf. this vol., 291).—Viscosities of MeOH and  $CO_2$  at temp. up to 218° have been measured. The vals. for  $CO_2$  up to 140° agree with Batschinsky's formula. Deviations observed at higher temp. are discussed. F. L. U.

**Viscosity formula for binary mixtures, the association degrees of constituents being taken into consideration.** T. ISHIKAWA and T. BABA

(Bull. Chem. Soc. Japan., 1936, 11, 64–101).—Viscosity formulæ are applied to the published results of other observers. The characteristic consts. for various binary mixtures are tabulated. C. R. H.

**Interpretation of diffusion and viscosity curves in binary mixtures.** H. LEMONDE (Compt. rend., 1936, 202, 731–733).—The interpretation of curves connecting the diffusion coeff. (*D*), the viscosity ( $\eta$ ), and the product *D* $\eta$  with the composition of EtOH- $H_2O$  mixtures at 10° and 18° is discussed. The *D*- $\eta$  curve leads to the same conclusions about association as the b.-p. curve. H. J. E.

**Viscosity of solutions of phenol and of camphor.** A. CASTIGLIONI (Gazzetta, 1935, 65, 1214–1217; cf. A., 1934, 1166).—PhOH, like camphor (I), lowers the viscosity of oils. Data are recorded for mixtures of olive oil and a second liquid ( $CHCl_3$ ,  $C_6H_6$ , PhMe, xylene) and for mixtures of vaseline and PhMe, before and after the addition of 10% of (I). For certain mixtures, the viscosity is not affected by the addition of (I). O. J. W.

**Viscosity of the critical mixture for the ternary system benzene-alcohol-water.** O. KIMURA (Bull. Chem. Soc. Japan., 1936, 11, 57–63).—Viscosity data for mixtures in the crit. region indicate that increase of viscosity, accompanied by opalescence, is due to the presence of colloid particles, supposed to be  $C_6H_6$  droplets covered with a thin EtOH film. The concn. of the colloid particles is of the order of 0.0001 near the crit. point. C. R. H.

**Magnetic susceptibility and other properties of binary mixtures of organic liquids.** V. C. G. TREW and J. F. SPENCER (Trans. Faraday Soc., 1936, 32, 701–708; cf. A., 1934, 137).—The density,  $n$ , heat of mixing, sp. heat, and magnetic mass susceptibility have been determined for mixtures of  $C_6H_6$  with PhMe, *m*-xylene with  $C_6H_6$ , PhMe,  $PhNO_2$ , and  $NH_2Ph$ , and  $PhNO_2$  with  $NH_2Ph$ . Deviations from the mixture law are shown by all the pairs and for all the properties considered. The mol. magnetic susceptibility is a more nearly additive property than the others studied. F. L. U.

**Diamagnetic susceptibility of sulphuric acid-water mixtures.** B. N. RAO (Proc. Indian Acad. Sci., 1936, 3, A, 188–192).—Deviations from additivity are attributed to the formation of  $H_2SO_4 \cdot 2H_2O$ . O. D. S.

**Condensation and b.p. curves of nitrogen-carbon monoxide mixtures up to 17 atmospheres.** F. STECKEL (Physikal. Z. Sovietunion, 1935, 8, 337–341).—The data are tabulated and show good agreement with the theory of Roozeboom. R. S.

**Heats of vaporisation of ternary mixtures.** V. FISCHER (Ann. Physik, 1936, [v], 25, 728–736).—Theoretical. Expressions are deduced for heats of vaporisation at const. pressure and temp., and these are used to calculate heats of mixing and entropy changes. L. J. J.

**Rectification of ternary mixtures, especially oxygen-nitrogen-argon mixtures.** H. HAUSEN (Forsch. Ingenieurw., 1935, 6, A, 9–22; Chem. Zentr., 1935, ii, 730).—Equilibrium diagrams between

1 and 5 atm. are given and methods for calculating the composition of the products of rectification under various conditions are discussed. J. S. A.

**Classification of binary, ternary, and quaternary alloys.** E. JANECKE (Z. Elektrochem., 1936, 42, 128—138).—A lecture. F. L. U.

**Binary systems of alkali metals. II.** G. GORIA (Gazzetta, 1935, 65, 1226—1230; cf. this vol., 23).—Thermal diagrams for the systems Na-Cs, K-Cs, and Rb-Cs are recorded. The first shows the formation of the compound Na<sub>2</sub>Cs, a eutectic at -28° with 7.0 wt.-% Na, and no solid solution formation. The second suggests the formation of the compound KCs. In the third system there is a eutectic at -39° (13 wt.-% Rb) but neither compound nor solid solution formation is indicated. O. J. W.

**Structure of some alloys of copper.** W. BRONIEWSKI (Rev. Mét., 1935, 32, 649—657).—The constitution and properties of binary alloys of Cu with Ni, Ag, Al, Zn, Sn, and Au are reviewed. E. H. B.

**Elastic after-effect in the ordered Cu-Au alloys. (Elastic after-effect of the first kind.)** V. S. GORSKI (Physikal. Z. Sovietunion, 1935, 8, 562—571; cf. A., 1935, 439).—An after-effect amounting to 60—100% of the elastic deformation is shown by polycryst. alloys; for single crystals the corresponding magnitude of the after-effect is 10—60%. The influence of temp. on the time factor involved has been examined in both polycryst. material and single crystals. Results are in agreement with theory. A. J. M.

**Transitions in alloys. IV. Theory of arrangement processes and diffusion in mixed crystals of AuCu.** V. S. GORSKI (Physikal. Z. Sovietunion, 1935, 8, 443—356).—Mathematical. The temporary change in the degree of orderliness and the diffusion coeff. for an ordered CuAu lattice has been calc. by three methods: atom migration in the inter-lattice plates, migration of empty lattice plates, and direct atom plate alternation. Experimental data disagree with the vals. given by each of these methods. W. R. A.

**Gold-copper alloys.** W. BRONIEWSKI and K. WESOŁOWSKI (Ann. Physik, 1936, [v], 25, 757—758).—Polemical, against Le Blanc and Wehner (A., 1935, 1198). L. J. J.

[Gold-copper alloys.] M. LE BLANC and G. WEHNER (Ann. Physik, 1936, [v], 25, 759—760).—A reply to the above. L. J. J.

**Electrical conductivity and equilibrium diagram for binary alloys. XVIII. System palladium-cobalt.** G. GRUBE and H. KÄSTNER (Z. Elektrochem., 1936, 42, 156—160; cf. A., 1935, 291).—Data for the f.p. and m.p., variation of sp. resistance with temp., and Curie temp. of alloys of Pd and Co have been determined. The phase-equilibrium diagram is given. F. L. U.

**Equilibrium diagram of the magnesium-rich magnesium-aluminium-silicon ternary system.** H. SAWAMOTO (Suiyo-Shi, 1935, 8, 713—727).—The

ternary eutectic temp. coincides with that of the Mg-Al binary system at 437° (Al 32.7, Mg 67.3%).

CH. ABS. (e)

**Effect of nickel on the limits of the  $\alpha$ -phase of copper-aluminium alloys.** V. GRIDNEV and G. KURDJUMOV (Metallwirts., 1936, 15, 229—231, 256—259).—Additions of 2% and 4% Ni reduce the limit of the  $\alpha$ -range from 9.8 to 8.6% Al at the eutectoid temp., and raise the latter from 570° to 605°. Below this temp. the  $\alpha$ -range is const. in alloys containing 2% Ni, but narrows slightly with falling temp. when 4% Ni is added. The eutectoid point is displaced to higher Al contents. C. E. H.

**Spectrographic study of modifications undergone by the surface of light alloys; application to duralumin.** H. TRICHÉ (Compt. rend., 1936, 202, 745—747).—The spectrum obtained with a high-frequency spark between a Au wire and a duralumin electrode has been examined. After electrolysis in conc. aq. H<sub>2</sub>CrO<sub>4</sub> the intensity of the lines of Cu, Si, and Ca became much feebler, or even disappeared. The spectrum was unaltered after electrolysis in H<sub>2</sub>SO<sub>4</sub>. After short treatment with H<sub>2</sub>CrO<sub>4</sub>, electrolysis in H<sub>2</sub>SO<sub>4</sub> restores the surface to its initial state (as judged by the spark spectrum), but after prolonged treatment with H<sub>2</sub>CrO<sub>4</sub> the H<sub>2</sub>SO<sub>4</sub> electrolysis merely increases the thickness of the surface film. H. J. E.

**Special magnetic behaviour of cold-rolled iron-nickel alloys. (Development of isoperms.)** O. DAHL and J. PFAFFENBERGER (Metallwirts., 1935, 14, 25—28; Chem. Zentr., 1935, ii, 659).—Binary Fe-Ni alloys, like those containing Cu, show isperm properties, but these can be made use of only if the hysteresis is depressed. X-Ray investigation shows a well-developed cubic macrostructure. J. S. A.

**Compensation of nickel-beryllium alloys.** W. GERLACH (Naturwiss., 1936, 24, 218).—An alloy containing 2% Be is weakly magnetic after heating to 1200° and quenching. After annealing at 500° with mechanical compensation, the magnetisation increases by 50%, and the coercive force, residual magnetism, and Curie point also show a rise. The phenomenon is due to the separation during the annealing of Be from the Ni-Be mixed crystals, which are supersaturated at low temp. A mixed crystal with higher Curie point results. There is also considerable distortion of the Ni lattice. The distorted lattice is very stable, and the magnetic properties are not changed by long heating at 300°. A. J. M.

**Critical solution temperatures of aliphatic acids with nitromethane.** G. BROUGHTON and D. C. JONES (Trans. Faraday Soc., 1936, 32, 685—689; cf. A., 1934, 477).—Crit. solution temp. of mixtures of MeNO<sub>2</sub> with normal saturated fatty acids are as follows: C<sub>6</sub> (hexoic) -3.4°, C<sub>8</sub> 34.85°, C<sub>9</sub> 48.60°, C<sub>12</sub> 78.90°, C<sub>16</sub> 104.55°, C<sub>18</sub> 114.0°. F. L. U.

**Calculation of the solubility of a mixture of hydrogen and nitrogen in water at 25° in the pressure range 50—1000 atmospheres.** J. KIEL-

LAND (J. Amer. Chem. Soc., 1936, 58, 426—427).—Theoretical. E. S. H.

**Solubility of nickel sulphate in mixtures of sulphuric acid and water.** A. V. BABAEVA and E. I. DANILUSCHKINA (Z. anorg. Chem., 1936, 226, 338—340).—The solubility of  $\text{NiSO}_4$  in  $\text{H}_2\text{SO}_4$ - $\text{H}_2\text{O}$  mixtures has been measured at 0°, 20°, 40°, and 80°. Besides the known hydrates  $\text{NiSO}_4 \cdot 7\text{H}_2\text{O}$ ,  $\text{NiSO}_4 \cdot 6\text{H}_2\text{O}$  (blue),  $\text{NiSO}_4 \cdot 6\text{H}_2\text{O}$  (green), and  $\text{NiSO}_4 \cdot 2\text{H}_2\text{O}$ , the hydrate  $\text{NiSO}_4 \cdot 5\text{H}_2\text{O}$  (green) has been found to occur at 40° in presence of higher  $[\text{H}_2\text{SO}_4]$ . J. W. S.

**Solubility of monometric  $\text{As}_2\text{O}_3$  in acids and compounds  $\text{AsXO}_4$ .** D. GHIRON and G. MANGILI (Gazzetta, 1935, 65, 1244—1249).—The solubility in dil. acid solutions ( $< 1.0M$ ) is approx. the same as in  $\text{H}_2\text{O}$ , but the rate of dissolution is  $>$  in the acid solutions. In more conc. acid solutions the solubility depends on the basicity rather than on the strength of the acid, and is greatly increased in  $\text{H}_3\text{AsO}_4$  and in  $\text{H}_3\text{PO}_4$ . The existence of the compounds  $\text{AsAsO}_4$  and  $\text{AsPO}_4$  is confirmed. O. J. W.

**Solubility of potassium silicofluoride under different conditions.** A. A. VASILIEV and N. N. MARTJANOVA (J. Appl. Chem. Russ., 1936, 9, 152—154).—At 17° the solubility in  $\text{H}_2\text{O}$  is 0.1147, in 50%  $\text{EtOH}$  0.0042, in saturated aq.  $\text{KNO}_3$  and  $\text{KCl}$  0.0055 and 0.0054, respectively, and in 50%  $\text{EtOH}$  (containing 2%  $\text{KCl}$ ) 0.0022 g. per 100 ml. When used for washing the ppt., 100 ml. of the last named solution dissolve 0.9 mg. of  $\text{K}_2\text{SiF}_6$ . R. T.

**Solubility of sodium naphthalene-1:6-disulphonate in aqueous sodium chloride at 15°.** N. A. TOLMATSHEV (Anilinokras. Prom., 1935, 5, 219—220).—The solubility falls from 18% in  $\text{H}_2\text{O}$  to 1% in 25%  $\text{NaCl}$ . R. T.

**Congruent solubility of dolomite.** F. HALLA (Z. physikal. Chem., 1936, 175, 396—399).—Whether a double carbonate dissolves in  $\text{H}_2\text{O}$  congruently or incongruently is independent of the pressure of  $\text{CO}_2$  above the solution. R. C.

**Influence of foreign ions on the double [zinc] mercuric thiocyanate reaction.** B. V. J. CUVELIER and F. BOSCH (Natuurwetensch. Tijds., 1936, 18, 9—11).—The solubility of  $\text{ZnHg}(\text{SCN})_4$  in various salt solutions increases in the order  $\text{NaNO}_3 < \text{Na}_2\text{SO}_4 < \text{NaCl} < \text{NaBr} < \text{NaI}$ . The solubility in aq.  $\text{NaNO}_3$  is  $\times$  in  $\text{H}_2\text{O}$ , and for its determination Zn should therefore be in the form of nitrate (cf. A., 1935, 441, 721, 1068). D. R. D.

**Simultaneous solubility of sulphur and iodine in carbon tetrachloride.** A. A. JAKOVKIN and P. A. ARCHANGELSKI (Z. anorg. Chem., 1936, 226, 350—352).—At 0° the solubility of S in  $\text{CCl}_4$  is almost unaltered in presence of I, whilst the solubility of I is slightly increased. At 25° the solubility of each solute is increased in presence of the other, equilibrium being reached with 0.178 g. of I and 0.137 g. of S per 100 c.c. of solution. The results can be explained by the formation of a small amount of an unstable compound between the solutes. J. W. S.

**Liquid ammonia as a solvent for inorganic compounds. III. Vapour pressure measure-**

**ments.** M. LINHARD (Z. physikal. Chem., 1936, 175, 438—458; cf. A., 1934, 138).—The v.p. of solutions of alkali chlorides, bromides, and iodides, and of alkali and alkaline-earth nitrates have been determined at 0° from 0.2N to saturation. The ionisation in liquid  $\text{NH}_3$  solution is much  $<$  in aq. solution at the same concn. With  $\text{NH}_4\text{Cl}$ ,  $\text{AgI}$ , and alkaline-earth nitrates there is appreciable association even at small concns. The solvation of the ions and the tendency to association in conc. solution and in the ammoniated cryst. salts largely run parallel. Solvation increases from the chlorides to the iodides and from the Cs to the Na salts. The solubility increases, in general, in the same order, and for a series of salts with a common ion increases as the solvation increases and the lattice energy of the salt diminishes. With the alkaline-earth nitrates solvation is especially high, owing to the double charge of the cation, and the solubility falls with increasing at. vol. of the metal. The Raman spectrum of  $\text{NH}_3$  solutions of  $\text{AgI}$  indicates the presence of polymerised mols. R. C.

**Supersaturation.** R. E. LIESEGANG (Scientia, 1935, 57, 345—353; Chem. Zentr., 1935, ii, 476).—A discussion. H. J. E.

**Growth of crystals. VIII. Stabilising action of cations which accelerate the crystal growth on the supersaturated solution.** T. YAMAMOTO (Bull. Inst. Phys. Chem. Res. Japan, 1936, 15, 183—200).—Data for the supersaturation, crystallisation temp., and supersolubility of  $\text{KCl}$ ,  $\text{NH}_4\text{Cl}$ , and  $\text{KCl}$  in presence of  $\text{Pb}^{++}$ , and of  $\text{NH}_4\text{Cl}$  in presence of  $\text{Mn}^{++}$ , are given and discussed. N. M. B.

**Distribution of radium in crystals of radium-containing barium salts.** (MME.) B. E. MARQUES (J. Chim. phys., 1936, 33, 219—225).—A comparison of the effects produced on a photographic plate by outer and inner crystal faces has shown that  $\text{BaBr}_2$  crystals which contain  $\text{RaBr}_2$  have a higher  $[\text{Ra}]$  near the centre than in the outer layers. Doerner and Hoskins' formula holds for the distribution in a single crystal as well as for the distribution between solid and liquid phases. J. W. S.

**Calorimetric investigation of adsorption of light and heavy hydrogen on active nickel.** A. MAGNUS and G. SARTORI (Z. physikal. Chem., 1936, 175, 329—341).—The rate of absorption at 0° and 25° and initial pressures of 0.25—1.25 mm. has been studied by observations on the heat evolved and the change in pressure. The results agree with the view that the sorption consists in an almost instantaneous physical adsorption of a small amount of H which undergoes adsorption at a high but measurable rate on the active centres; the sorbed H then slowly changes into another state, perhaps the dissolved state, the heat effect accompanying this process being too small to be detectable calorimetrically. H is adsorbed much more rapidly than D, the heat of activation being  $\sim 1.0$  as compared with  $\sim 1.7$  kg.-cal. The heats of adsorption vary little with temp. R. C.

**Absorption of gases on sodium chloride.** F. C. TOMPKINS (Trans. Faraday Soc., 1936, 32, 643—653).—Adsorption isotherms for  $\text{NO}$ ,  $\text{CO}$ ,  $\text{CH}_4$ ,  $\text{N}_2$ ,

A, and  $O_2$  at  $-183^\circ$ , and for  $(CN)_2$ ,  $CO_2$ ,  $N_2O$ , and  $C_2H_4$  at  $-78.2^\circ$  on cryst. NaCl have been determined at pressures  $> 0.4$  mm. The dipole gases are highly adsorbed according to the val. of their electric moment. Adsorption of non-polar gases increases with their polarisability. The shape of the isotherms is explained. No lateral diffusion of adsorbed mols. occurs at  $-192^\circ$  or  $-183^\circ$ , but slow secondary absorption is observed at  $-78.2^\circ$ . Heats of adsorption of A,  $CH_4$ , and CO in the range  $-183^\circ$  to  $-192^\circ$  are  $<$  those theoretically expected. F. L. U.

**Adsorption isotherm for lead chloride as an adsorbent.** F. DURAU and G. TSCHOEPE (Naturwiss., 1936, 24, 156—157).—The adsorption of  $C_6H_6$ ,  $C_6H_{14}$ , and  $COMe_2$  on purified  $PbCl_2$  has been examined by a method based on measurements of vol. The adsorption-pressure curves for dry  $C_6H_6$  and  $C_6H_{14}$  are linear at low pressures, but that for  $COMe_2$  dried over  $CaCl_2$  shows some deviations due to  $H_2O$  vapour not removed by  $CaCl_2$ . The curves deviate from the linear as the saturation pressure is approached and do not agree with Langmuir's theory. A. J. M.

**Mathematical formula for determination of the total adsorbable substance of an adsorption system by means of repeated extractions.** J. VOICU (Kolloid-Z., 1936, 74, 316—328).—Mathematical. E. S. H.

**Structural changes taking place during the ageing of precipitates. IX. Mechanism of adsorption of lead on aged barium sulphate.** I. M. KOLTHOFF and W. M. MACNEVIN (J. Amer. Chem. Soc., 1936, 58, 499—504; cf. this vol., 284).—Th-B is removed from aq. solution when shaken with pptd.  $BaSO_4$  (a) by rapid exchange of the ions with  $Ba^{++}$  in the surface, (b) by incorporation of exchanged Th-B in the  $BaSO_4$  lattice as a result of recrystallisation. The rate of recrystallisation depends on the degree of perfection of  $BaSO_4$ , the temp. and composition of the solution; it is reduced markedly by addition of 50% EtOH. Th-B can be desorbed by adding a large excess of Ba salt. E. S. H.

**Separation of amino-acids. I, II. Adsorption of diamino-acids on Japanese acid clay.** M. MASHINO and N. SHIKAZONO (J. Soc. Chem. Ind. Japan, 1936, 39, 54—55B).—Japanese acid clay, especially when activated by treatment with HCl, is a powerful absorbent for the  $(NH_2)_2$ -acids from hydrolysed soya-bean protein. Adsorption is a max. at  $pH$  5—7 and falls rapidly in alkaline media. The following amounts % of  $NH_2$ -acids were absorbed from 0.5% solutions: glycine 8.45, alanine 9.38, leucine 6.5, phenylalanine 11.14, aspartic acid 3.55, glutamic acid 4.18, arginine 86.80, histidine-HCl 84.80, lysine-2HCl 62.92%. Active C adsorbs  $NH_2$ - and  $(NH_2)_2$ -acids equally;  $SiO_2$  gel is much less effective. S. C.

**Application of Bangham and Sever's formula of sorption velocity.** I. HIGUTI (Bull. Inst. Phys. Chem. Res. Japan, 1936, 15, 96—108).—Bangham and Sever's formula  $\log[S/(S-x)] = kt^n$ , where  $S$  is the saturation val.,  $x$  the quantity adsorbed at time  $t$ , and  $k$  and  $n$  are consts., has been found to

hold for a wide range of published results.  $k$  and  $n$  change abruptly near the saturation point. The formula holds for chemisorption as well as occlusion, but when several compounds are formed, as with  $NH_3$  and  $AgCl$ ,  $n$  and  $k$  are sp. for each compound. R. S. B.

**Surface tension of soap solutions.** N. K. ADAM (Trans. Faraday Soc., 1936, 32, 653—656).—Increase in the surface tension of soap solutions caused by adding small amounts of alkali is due to suppression of hydrolysis, which is greatly magnified in the surface layer because the surface activity of the acid, or acid soap,  $>$  that of neutral soap. The adsorption of neutral K dodecoate is calc. from published data. The adsorbed film is gaseous. F. L. U.

**Transport numbers of ions through membranes, as a characteristic of their electro-osmotic properties.** I. I. I. SHUKOV and A. I. JURSHENKO (J. Appl. Chem. Russ., 1936, 9, 9—22).—The  $\zeta$ -potentials of membranes (porcelain, gelatin, cellulose, bakelite paper, leather) interposed between the anode and cathode in the electrolysis of aq. KCl-HCl, at different  $p_H$ , do not run parallel with the transport nos. of the ions within the membranes. In the case of leather different results are obtained according to which side is directed towards the anode or cathode. R. T.

**Cryoscopy of solutions in formamide.** I. F. H. GETMAN (Rec. trav. chim., 1936, 55, 231—243).—From measurement of the surface tension between  $4^\circ$  and  $78^\circ$  the association factor for  $HCO \cdot NH_2$  is calc. to be about 6 at room temp. The f.p. const. is 3.50, and  $n_D^{25} = 1.44682$ . The mol. wts. of  $HCO \cdot NH_2$  and  $H_2O$ , each dissolved in the other, are those of non-associated mols. A modification of the Beckmann f.-p. method is described. F. L. U.

**Electrolytic solutions. XVIII. Molecular polarisations and polar moments of electrolytes in benzene solutions.** J. A. GEDDES and C. A. KRAUS. XIX. Conductance of mixed electrolytes in ethylene chloride. Tetrabutyl- and tetramethyl-ammonium picrates. D. J. MEAD, R. M. FUOSS, and C. A. KRAUS (Trans. Faraday Soc., 1936, 32, 585—593, 594—606).—XVIII. Dielectric consts. of  $C_6H_6$  solutions of various alkyl-ammonium salts have been determined at  $25^\circ$  at concns. down to  $4 \times 10^{-5} N$ . Polar moments ranging from 7 to  $20 \times 10^{-18}$  indicate the existence of electrical dipoles. Polarisation-concn. curves of three types are obtained, the form being related to the structure of the ions concerned, and determined by the association of dipoles. The results agree with f.p. and conductance measurements in  $C_6H_6$  (A., 1933, 1120; 1934, 1304).

XIX. Conductances of solutions of  $NMe_4$  and  $NBu_4$  picrates, and of mixtures of the two, in  $C_6H_6$ , have been determined at  $25^\circ$  between  $10^{-5}$  and  $10^{-3} N$ . Up to about  $10^{-4} N$ , conductances of the mixtures calc. theoretically agree within 0.1% with the observed vals. Improved technique for making dilutions with a volatile solvent is described. F. L. U.

**Polar structure of betaines.** II. G. DEVOTO and M. ARDISONE (*Gazzetta*, 1935, 65, 1235—1239; cf. A., 1934, 1100).—Further measurements of the dielectric const. of aq. solutions of betaines of varying concn. show that the latter all have a polar amphoteric structure. O. J. W.

**Highly polymerised compounds.** CXXXV. [Viscosity of solutions of aliphatic hydrocarbons.] H. STAUDINGER (*Helv. Chim. Acta*, 1936, 19, 204—218).—Criticism of a paper by Meyer and van der Wyk (A., 1935, 1318). F. L. U.

[Viscosity of solutions of aliphatic hydrocarbons.] K. H. MEYER and A. VAN DER WYK (*Helv. Chim. Acta*, 1936, 19, 218—221).—A reply to the above. F. L. U.

**Constitution of ferric oxide sols.** W. HELLER, O. KRATKY, and H. NOWOTNY (*Compt. rend.*, 1935, 202, 1171—1173).—By magneto-optical and X-ray observations of the sols over several years it has been shown that the normal course of the ageing process is  $\text{FeOCl} \rightarrow \beta\text{-FeO}\cdot\text{OH} \rightarrow \alpha\text{-FeO}\cdot\text{OH}$ . The time required varies with the method of prep. of the sol. M. S. B.

**Viscosity of aqueous suspensions.** R. HERMANN (*Forsch. Ingenieurw.*, 1935, A, 6, 1—8; *Chem. Zentr.*, 1935, ii, 815).—Aq. suspensions possess no true viscosity. The  $\eta$  val. derived from the Hagen-Poiseuille law is a function of the tangential stress at the wall and decreases to a const. val. at high tangential stress.  $\eta$  increases on ageing. Aq. suspensions exhibit no external friction. J. S. A.

**Viscosity of suspensions and solutions.** III. **Viscosity of sphere suspensions.** (Calculation of wall effect and reciprocal influence in viscosity, with rotating spheres.) E. GUTH and R. SIMHA (*Kolloid-Z.*, 1936, 74, 266—275; cf. this vol., 426).—Mathematical. E. S. H.

**Viscosity of suspensions and solutions.** IV. **Viscosity of sphere suspensions.** F. EIRICH, M. BUNZL, and H. MARGARETHA (*Kolloid-Z.*, 1936, 74, 276—285).—Measurements made with the Couette, falling-sphere, and capillary viscosimeters agree with Einstein's relation between  $\eta$  and the vol. of disperse phase. E. S. H.

**Tyndall light of milk.** T. KATSURAI (*Kolloid-Z.*, 1936, 74, 287—288).—The turbidity-concn. relations of whole and skimmed milk have been determined in the region of visible  $\lambda$ , and the theoretical aspects are discussed. E. S. H.

**Stability of emulsions.** H. M. CASSEL (*Nature*, 1936, 137, 405).—Theoretical. L. S. T.

**Emulsions.** V. **Heterogeneous regions of the sodium oleate-phenol-xylene-water system and the corresponding binary and ternary systems.** J. WEICHERTZ and N. PLETENJEVA (*Kolloid-Z.*, 1936, 74, 330—343; cf. A., 1932, 994, 1086).—Equilibria in the above systems have been determined at 25°. E. S. H.

**Observations of the coagulation of cellulose acetate under the ultramicroscope.** K. ATSUKI and S. OKAJIMA (*J. Soc. Chem. Ind. Japan*, 1936, 39, 57—58B).—When cellulose acetate in  $\text{CHCl}_3$  is

coagulated by EtOH the behaviour is similar to that observed when suspensoids are coagulated by electrolytes; the particles are probably rod-shaped. The rate of coagulation is expressed by Smoluchowski's equation  $1/n = 1/n_0 + kt$ , in which  $n$  is the no. of particles. A. G.

**$\zeta$ -Potential and stability of cellulose [nitrate and] ethers.** S. GLIKMAN and E. MEDVEDKOV (*J. Chim. phys.*, 1936, 33, 150—160; cf. A., 1934, 1069).— $\zeta$ -Potentials have been determined by the method of electrophoresis under the ultramicroscope using (a) lyophobes present as impurity in the sol, and (b) added lyophobes such as AgI. The  $\zeta$ -potential decreases with the cellulose nitrate concn. to a limiting val. corresponding to the adsorption max. This is the same for different cellulose nitrate fractions.  $\zeta$ -Potentials of benzyl- and ethyl-cellulose in various solvents have also been derived. Increasing concn. of salts lowers the potential and in the case of  $\text{CaCl}_2$  the charge may be reversed, whilst in different  $\text{COMe}_2\text{-H}_2\text{O}$  mixtures there is a sharp increase corresponding with the change lyophile  $\rightarrow$  lyophobe (16—18%  $\text{H}_2\text{O}$ ). It is inferred that the  $\zeta$ -potential is not the essential factor determining the stability of colloids. R. S.

**Mechanism of coagulation by ultrasonic waves.** K. SÖLLNER and C. BONDY (*Trans. Faraday Soc.*, 1936, 32, 616—623; cf. A., 1935, 820).—Coagulation of emulsions or suspensions by ultrasonic waves is primarily due to a "radiation pressure," caused by diffraction of sound energy by the individual particles, imparting to the latter a movement which results in a kind of orthokinetic coagulation. When stationary waves are produced the coagulating effect is accentuated by the increased concn. of the disperse phase through accumulation of particles at the nodes, if the particles are less dense than the dispersion medium, or at the antinodes if they are denser. This effect is most marked with large ( $> 1\mu$ ) particles, and hardly observable with those of truly colloidal size. The limiting concn. of an emulsion formed by ultrasonic radiation is the resultant of the formative and destructive actions which proceed simultaneously. If the energy supplied is  $<$  the crit. val., or if cavitation is prevented by applying external pressure, coagulation only takes place. F. L. U.

**Physical chemistry of amino-acids, peptides, and related substances.** VI. **Densities and viscosities of aqueous solutions of amino-acids.** J. DANIEL and E. J. COHN (*J. Amer. Chem. Soc.*, 1936, 58, 415—423; cf. A., 1935, 1467).—The increase of apparent mol. vol. of the free  $\text{NH}_2$ -acids with concn. is greater with increasing dipole moment and diminishing hydrocarbon chain. The increase of  $\eta$  with length of hydrocarbon chain is given by  $(\eta/\eta_0) - 1 = (0.052 + 0.10 \times n_{\text{OH}})C = 2.5k\varphi$ , where  $\varphi$  is the vol. fraction occupied by the solute,  $C$  its concn., and  $V$  its mol. vol. Solutions of the Na salts are more viscous than those of the free acids. E. S. H.

**Gans effect, streaming double refraction, and particle shape in protein solutions.** E. WÖHLISCH and B. BELONOSCHKIN (*Biochem. Z.*, 1936, 284, 353—364).—The polarisation of Tyndall light and the presence of streaming double refraction have been examined in sols of ovalbumin, caseinogen, serum-

and ovo-globulin, fibrin, fibrinogen, and myosin. The behaviour is compared with that of inorg. sols and discussed with reference to particle shape. F. O. H.

**Determination of diffusion constants of proteins by a refractometric method.** O. LAMM and A. POLSON (Biochem. J., 1936, 30, 528—541).—A refractometric method for measuring diffusion consts. of proteins is described and several methods for calculating the diffusion consts. from the curves are discussed. The consts. of ovalbumin (I), human CO-haemoglobin (II), serum-albumin (III), gliadin, erythrocrucorin, and lactoglobulin are determined and it is shown that the consts. for (I), (II), and (III) increase greatly on dilution below 0.5%. In monodisperse systems the diffusion follows closely the ideal dispersion law, but in polydisperse systems deviations from normal curves are obtained. The refractive indices are calc. from the areas included by the diffusion curves and the mol. wts. from the diffusion and sedimentation consts. P. W. C.

**Hæmocyanin in heavy water.** T. SVEDBERG and I. B. ERIKSSON-QUENSEL (Nature, 1936, 137, 400—401).—Determinations of the sedimentation const. for solutions of hæmocyanin (I) containing different amounts of D<sub>2</sub>O indicate that the mol. of (I) has the same wt. and shape in D<sub>2</sub>O as in H<sub>2</sub>O. The  $p_H$  vals. at which dissociation occurs in buffered 94.5% D<sub>2</sub>O and in buffered H<sub>2</sub>O are the same, but since [D'] is different from [H'] the dissociation points actually alter. E.m.f. measurements indicate that the buffers in D<sub>2</sub>O are 0.5  $p_H$  more alkaline than the corresponding buffers in H<sub>2</sub>O. The isoelectric point and the stability curve of (I) in D<sub>2</sub>O probably change by the same amount. L. S. T.

**Preparation of thorium gels.** S. M. MEHTA, M. U. PARMAR, and M. PRASAD (J. Indian Chem. Soc., 1936, 13, 69—71).—Clear, firm gels may be prepared from Th(NO<sub>3</sub>)<sub>4</sub> and H<sub>3</sub>PO<sub>4</sub> and these exhibit the sol-gel transformation. E. E. A.

**Thorium phosphate gels.** M. U. PARMAR, S. M. MEHTA, and M. PRASAD (Proc. Indian Acad. Sci., 1936, 3, A, 107—118; see preceding abstract).—The time of setting ( $t$ ) of Th phosphate gels is diminished by increasing [H<sub>3</sub>PO<sub>4</sub>], by rise in temp., and by addition of electrolytes. It is increased by increase in [Th(NO<sub>3</sub>)<sub>4</sub>] and by the addition of NaOH, MeOH, EtOH, PrOH, and glycerol. The effect produced by HCl, HNO<sub>3</sub>, and H<sub>2</sub>SO<sub>4</sub> varies with the concn. of the acid. O. D. S.

**Gelation of albumin in aqueous propyl alcohol containing salts. Thixotropy and syneresis of albumin-propyl alcohol gel.** B. JIRGENSONS (Kolloid-Z., 1936, 74, 300—305).—Sols of 2.5% albumin in 40—60 vol.-% PrOH, containing 0.5 mol. per litre of K or Na salt, set to a reversible gel at 60—70°. Anions accelerate the gelation in the order SO<sub>4</sub><sup>2-</sup> > Cl<sup>-</sup> > NO<sub>3</sub><sup>-</sup> > Br<sup>-</sup> > I<sup>-</sup> > CNS<sup>-</sup>. The gels are thixotropic and undergo syneresis. E. S. H.

**Mesomorphic state of soaps and washing materials.** W. SECK [with G. ŠKRILECZ] (Angew. Chem., 1936, 49, 203—206).—The Na salts of stearic, hydroxystearic, hydroxystearin- and stearyl-sulphonic (I) acids, cryst. directly from solution, are shown

(X-ray) to form single mols. inclined at 39—41° to the basal plane. The formation of double mols. observed previously by other workers is attributed to orienting polar effects due to crystallisation at a foreign solid surface. The take-up of H<sub>2</sub>O by the anhyd. soaps leads to two-dimensional swelling; the spacing which corresponds with the breadth of the mols. persists in the case of (I) down to 10% solutions. The formation of nematic hydrogels on dissolution of the dry soaps is indicated. The effect of interfaces in promoting the transition between the nematic and smectic states is discussed, and related to the detergent action of soaps. J. S. A.

**Rôle of coacervation in the resorption of fats.** A. DE KUTHY (J. Chim. phys., 1936, 33, 247—249; cf. A., 1929, 466).—When 15 c.c. of a 5% EtOH solution of oleic acid are added to 50 c.c. of M/30-phosphate buffer solution of  $p_H$  6.5 and the mixture is then warmed to expel EtOH and mixed with 50 c.c. of 10% Na taurocholate solution, a clear solution is obtained which yields drops of coacervate when mixed with 0.4% hæmoglobin solution in the same buffer. Addition of acid to the solution produces coacervation only at  $p_H$  3.5—4.0, a condition never present in organisms. These observations are applied to explain the fact that fat particles are formed only after passage of the fatty acids through the membranes of the intestines. J. W. S.

**Influence of light intensity on the periodic formation of Ag<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> precipitates in gelatin.** V. K. NIKIFOROV and M. R. LEMECH (J. Chim. phys., 1936, 33, 250—256).—The "pressure" of rings produced by AgNO<sub>3</sub> and K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> diffusing in gelatin varies with the intensity of illumination ( $I$ ) according to the law  $\lambda_n I^k = a_n$ , where  $\lambda_n$  is the distance between the rings,  $a_n$  is a const., for any frequency, and  $k$  is a const. independent of frequency. The greater is the energy of the light quanta, the greater is the energy which is associated with the formation of rings. The results are explained on the wave theory of periodic reactions. J. W. S.

**Liesegang phenomena.** T. OKAYA (Proc. Phys.-Math. Soc. Japan, 1935, 17, 101—118).—The calc. energy of pptn. of Ag<sup>+</sup> in the formation of Liesegang rings is approx. 17.8 g.-cal. per mol. An expression is given for the diffusion coeff. of Ag<sup>+</sup> in gelatin. CH. ABS. (e)

**Dissociation of products of combustion.** W. L. DE BAUFRE (Combustion, 1935, 6, No. 11, 23—31).—The dissociation of H<sub>2</sub> and CO<sub>2</sub> is discussed. CH. ABS. (e)

**Thermodynamics of ammonia-water mixtures.** V. FISCHER (Forsch. Ingenieurw., 1935, A, 6, 57—66; Chem. Zentr., 1935, ii, 23).—Equilibrium data for the NH<sub>3</sub>-H<sub>2</sub>O system at 1 atm. and 10 atm. calc. from the heats of mixing and the contractions agree with experimental vals. J. S. A.

**Practical application of electrostatic valency. Strength of acids.** A. E. VAN ARKEL and G. CARRIÈRE (Chem. Weekblad, 1936, 33, 182—184).—Data relating to the strengths of inorg. acids and of bases of the NH<sub>3</sub> type are reviewed and the causes of the differences are discussed. D. R. D.

**Ionisation of lactic acid.** L. F. NINS and P. K. SMITH (J. Biol. Chem., 1936, 113, 145—152).—E.m.f. data between 0° and 50° for cells, without liquid junction, containing the lactates of Li, Ca, Sr, Ba, and Zn, show that the ionisation of lactic acid is greatest at 23.5°; the val. of  $pK$  at 25° is 3.862, at 37.5° is 3.872. F. A. A.

**Anomalies in the dissociation constant of some halogenated organic acids. II.** M. BETTI and M. MANZONI (Atti R. Accad. Lincei, 1935, [vi], 22, 284—287).—For the Cl- and Br-substituted acids  $o\text{-C}_6\text{H}_4\text{X}\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$   $K=1.35\times 10^{-4}$  and  $1.92\times 10^{-4}$ , respectively. O. J. W.

**Calculation of intramolecular atomic distances from dissociation constants of dibasic acids. IV. Acidity of aliphatic dithiols.** G. SCHWARZENBACH and A. EPPRECHT. **V. Dissociation constants of hydrazine.** G. SCHWARZENBACH (Helv. Chim. Acta, 1936, 19, 169—178, 178—182; cf. A., 1933, 665).—IV. Normal acidity potentials of  $\text{SH}\cdot[\text{CH}_2]_n\cdot\text{SH}$  ( $n=2-5$ ) in aq. EtOH are calc. from results of H electrode potential measurements at 20°. The dithiols are all extremely weak acids. The acidity increases as  $n$  decreases, owing to the influence of the second  $\cdot\text{SH}$ . The results are compared with those obtained for the corresponding dicarboxylic acids and diammonium ions.

V. H electrode potential measurements in  $\text{N}_2\text{H}_4$  give for  $K_1$   $8.5\times 10^{-7}$ . Colorimetric determination of the second stage gives  $K_2=8.9\times 10^{-16}$ . F. L. U.

**Chemical union of acids with one another.** J. A. CRANSTON and H. F. BROWN (J. Roy. Tech. Coll., 1936, 3, 569—575).—An acid may act as proton acceptor in presence of stronger acid and therefore come under definition of a base. Other factors, e.g., the symmetry of the ion produced, may favour this complex ion formation.  $[\text{H}^+]$  of aq. HCl shows an increase in the order  $\text{H}_3\text{PO}_4 > \text{H}_2\text{SO}_4 > \text{HClO}_4$ , when these acids are substituted for an equal vol. of  $\text{H}_2\text{O}$  in aq. HCl. Formation of complex ions, e.g.,  $\text{H}_4\text{PO}_4^+$ , accounts for this, and an explanation is given for the concomitant reduction in sp. conductivity of these mixed solutions (cf. A., 1928, 369). The behaviour of solutions obtained by absorption of dry HCl by  $\text{H}_3\text{PO}_4$  is ascribed to the initial formation of  $\text{H}_4\text{PO}_4\text{Cl}$ . D. C. J.

**Determination of basic dissociation constants and ionic products of solvents in acetic acid. I. Equations.** S. KILPI (Suomen Kem., 1936, 9, B, 7—8).—Equations are developed for calculating the consts. from the buffer capacity of the solutions in the initial stages of acid-base titrations. J. S. A.

**Determination of basic dissociation constants and the ionic product of the solvent in acetic acid. II. Experimental results.** S. KILPI (Suomen Kem., 1936, 9, B, 9).— $o\text{-NH}_2\cdot\text{C}_6\text{H}_4\cdot\text{CO}_2\text{H}$  has been titrated with  $\text{HClO}_4$  in AcOH (0.9% of  $\text{H}_2\text{O}$ ) and  $K_B$  and  $K_I$  calc. R. S.

**Dissociation constants of alkylamines.** G. SCHWARZENBACH (Helv. Chim. Acta, 1936, 19, 182—183).—Normal acidity potentials at 20° have been determined for  $\text{NH}_2\text{Me}$ ,  $\text{NH}_2\text{Pr}$ ,  $\text{NH}_2\text{Bu}$ , and  $n\text{-amylamine}$ . F. L. U.

**Activity coefficients of strong electrolytes.** S. KANEKO (J. Chem. Soc. Japan, 1935, 56, 411—414).—Mathematical. A simpler differential equation for strong electrolytes is given, and its solution is discussed. CH. Abs. (e)

**Theory of strong electrolytes and activity of cadmium chloride.** (MLLE.) M. QUINTIN (J. Chim. phys., 1936, 33, 111—126; cf. A., 1934, 492).—The e.m.f. of the cell  $\text{Cd (amalgam two phases)}|\text{CdCl}_2(c)|\text{AgCl}|\text{Ag}$  has been measured at different temp. When  $c>0.005M$  the plot of  $e$  against temp. gives two intersecting straight lines. This is attributed to the formation of a compound between AgCl and  $\text{CdCl}_2$ .  $E_0$  has been calc. using the method of Gronwall *et al.* (A., 1931, 1127), and the activity coeffs. at different temp. are given. The ionic radius is 3.8 Å. at 25° and it is inferred that the association of the ions is negligible. The method used is applicable up to concns. of 0.005M. R. S.

**Phase diagrams of low-melting mixtures. II. M.p. diagram of oxygen-nitrogen and the phase diagram of nitrogen-carbon monoxide.** M. RUHEMANN, A. LICHTER, and P. KOMAROV (Physikal. Z. Sovietunion, 1935, 8, 326—336; cf. A., 1935, 447).—Variation of sp. heat with temp. has been studied in a special calorimeter and the results applied to the derivation of phase diagrams.  $\text{N}_2$  and CO form two complete series of mixed crystals whilst the diagram for  $\text{N}_2+\text{O}_2$  shows a eutectic at 23%  $\text{N}_2$  and 50.1° abs. The latent heat of fusion of  $\text{O}_2\text{-N}_2$  is a min. at 69%  $\text{O}_2$ . R. S.

**Thermal diagram for system ferrous sulphide-cuprous sulphide. Determination of dissociation pressures of iron sulphides.** D. D. HOWAT (J. Roy. Tech. Coll., 1936, 3, 587—598).— $\text{Cu}_2\text{S}$  is sol. in FeS up to 20% and FeS in  $\text{Cu}_2\text{S}$  up to 40%; the eutectic at 970° corresponds with 61% FeS. The cooling curves for all melts containing from 95% to 55% FeS show a lower arrest point at 890—910°, and it is suggested that this may be due to dissociation of FeS. A method is described for the measurement of dissociation pressures of Fe sulphide mixtures which depends on the reducing action of  $\text{H}_2$ . D. C. J.

**Equilibrium between the sulphates of cobaltic chloropentammine and their sulphuric acid solutions.** L. O. TAO and W. S. MO (Compt. rend. 1936, 202, 846—848).—Equilibrium data for the system  $\text{Co}^{\text{III}}$  chloropentammine sulphate- $\text{H}_2\text{SO}_4\text{-H}_2\text{O}$  suggest the formation of  $[\text{CoCl}(\text{NH}_3)_5]\text{SO}_4\cdot 0.33\text{H}_2\text{SO}_4\cdot 2\text{H}_2\text{O}$ , which is not in agreement with any of the formulæ previously proposed. The establishment of equilibrium is very slow at room temp. and measurements were made at 35—50°. M. S. B.

**System naphthalene-hexachloroethane.** S. PARIJS (Z. anorg. Chem., 1936, 226, 425—428).—The m.-p. diagram of the system  $\text{C}_{10}\text{H}_8\text{-C}_2\text{Cl}_6$  shows a eutectic at 56.6° and a transition point at 71° corresponding with the change of  $\text{C}_2\text{Cl}_6$  from the triclinic to the cubic form. No transition point was observed at 125° (cf. A., 1912, i, 330). The heats of

fusion of  $C_{10}H_8$  and of the two forms of  $C_2Cl_6$  are 4.56, 4.5, and 2.01 kg.-cal. per mol., respectively.

J. W. S.

**Equilibrium of the light and heavy isotopes of hydrogen with crystalline cuprous chloride.**

A. F. KAPUSTINSKY (J. Amer. Chem. Soc., 1936, 58, 460—463).—The equilibrium has been studied at 320—400°. The entropy, free energy, and heat of formation of  $CuCl$ , and the equilibrium const. for reduction of  $HCl$  by  $D_2$  have been calc. E. S. H.

**$CaO, TiO_2, SiO_2-CaO, SiO_2-CaO, Al_2O_3, 2SiO_2$  system. I. Equilibrium diagram of the system  $CaO, SiO_2-CaO, Al_2O_3, 2SiO_2$ .** U. NISHIOKA (Kinz.-no-Kenk., 1935, 12, 168—171).—The diagram shows a eutectic at 1283° (57 wt.-%  $CaO, SiO_2$ ). CH. Abs. (e)

**Geometrical theory of heterogeneous equilibria.** E. SCHEIL (Z. Elektrochem., 1936, 42, 153—155).—The elements of a geometrical treatment of the phase rule, based on the principle that the boundary between two  $n$ -dimensional figures has  $n-1$  dimensions, is developed. F. L. U.

**Specific heat of concentrated aqueous lithium, sodium, and potassium chlorides.** A. J. BOGORODSKI and G. P. DEZIDERIEV (Trans. Kirov Inst. Chem. Tech. Kazan, 1935, No. 4—5, 29—40).—Data are recorded for 11.4—36.68%  $LiCl$ , 7.42—26%  $NaCl$ , and 6.95—24.8%  $KCl$ , for the range 16—34°. R. T.

**Specific heats of sodium hydroxide solutions.** J. W. BERTETTI and W. L. MCCABE (Ind. Eng. Chem., 1936, 28, 375—378).—The sp. heats of  $NaOH$  solutions (4—51 wt.-%) have been determined at 37—191° F. using the adiabatic method. The results agree with those of Richards and Gucker (A., 1929, 652) but the work of Tucker (A., 1915, ii, 674) seems to involve a const. error. R. S. B.

**Correction in calculation of the heat of formation of sodium ferrite.** M. MATSUI (J. Soc. Chem. Ind. Japan, 1936, 39, 55—56B; cf. A., 1934, 1174).—The heat of formation of  $Na_2Fe_2O_4$  is given as 34,714 g.-cal. M. S. B.

**Heat of formation of iron nitrides.** S. SATOH (Sci. Papers Inst. Phys. Chem. Res. Tokyo, 1936, 28, 271—276).—The heats of formation of  $Fe_4N$  and  $Fe_2N$  derived from the Nernst heat theorem and the equilibrium data of the systems  $Fe-NH_3-Fe_4N-H_2$  and  $Fe_4N-NH_3-Fe_2N-H_2$  are 4322 and 3090 g.-cal., respectively. The calorimetric vals. are 4460 and 3040 g.-cal., respectively. R. S. B.

**Heat of formation and specific heat of aluminium nitride.** S. SATOH (Sci. Papers Inst. Phys. Chem. Res. Tokyo, 1936, 29, 19—30).—The mean sp. heats of  $Al$  and of a specimen of  $AlN$  containing 10.18%  $Al$  were measured by the ice calorimeter in the intervals 0—100°, 0—420°, and 0—598°. The corresponding corr. vals. of the sp. heat of pure  $AlN$  are 0.193, 0.226, and 0.239, respectively. An equation for the true sp. heat is found, and using this, the heat of formation, computed from the equilibrium data of the reaction  $Al_2O_3+3C+N_2=2AlN+3CO$  at high temp., gives the result:  $Al+N=AlN+74,700$  g.-cal. N. M. B.

**Gallium and indium compounds. XI. Heat of formation of gallous oxide.** W. KLEMM and I. SCHNICK (Z. anorg. Chem., 1936, 226, 353—358).—By sublimation of mixtures of  $Ga_2O_3$  and  $Ga$ , products of composition between  $GaO$  and  $Ga_2O$  are obtained. Repetition of the sublimation with addition of  $Ga$  increases the  $Ga_2O$  content to about 84%. From the heat of combustion of this mixture  $Ga_2O+O_2 \rightarrow Ga_2O_3=175 \pm 2$  kg.-cal. per mol., whence the heat of formation of  $Ga_2O$  is  $82 \pm 2$  kg.-cal. and its heat of decomp. into  $Ga_2O_3$  and  $Ga$  is  $3.7 \pm 2$  kg.-cal. J. W. S.

**Free energy of ethylene hydration.** E. R. GILLILAND, R. C. GUNNESS, and V. O. BOWLES (Ind. Eng. Chem., 1936, 28, 370—372).—From equilibrium data for  $C_2H_4+H_2O \rightleftharpoons EtOH$  at 176—307°, with  $H_2SO_4$  as catalyst, the free energy of hydration in the gaseous phase is found to be  $26.9T-8300 \pm 500$  g.-cal. The val. 326,610 g.-cal. for the heat of combustion of  $C_2H_4$ , due to Rossini, is confirmed. R. S. B.

**Conductance of non-aqueous solutions. II. Temperature coefficient of conductivity.** A. S. COOLIDGE and H. E. BENT (J. Amer. Chem. Soc., 1936, 58, 505—506; cf. A., 1935, 1462).—Theoretical. The negative temp. coeff. is discussed and the rôle of the solvent in determining  $\Delta H$  and  $\Delta S$  emphasised. The calc. entropy of ionisation of  $Na$  triphenylboron is —60 entropy units. E. S. H.

**Measurement of absolute rates of migration of ions by the method of moving boundaries. II.** J. MUKHERJEE, R. MITRA, and N. SEN-GUPTA (J. Indian Chem. Soc., 1936, 13, 42—68; cf. A., 1935, 825).—Rising boundaries between  $HCl$  and picric acid,  $KCl$  and  $K$  picrate,  $NaCl$  and  $Na$  picrate,  $KCl$  and  $K$  compound of tetraiodoococin and also boundaries between mixtures of these electrolytes have been investigated. The variations of p.d. between two fixed planes with the linear displacement of the boundary have been directly measured and the abs. rates of migration of the "leading" and "indicator" ions have been calc. from such variations and the observed rate of motion of the boundary. Simultaneous measurements of the transference nos. of the leading ion have been made from observations of the vol. displacement of the boundary. The effects of the area of cross-section of the tube, the current strength, and the addition of small quantities of the leading solution to an approx. adjusted solution of the indicator electrolyte, have been studied. Light is thrown on the mechanism of concn. adjustments at and near the boundary, whilst the need of securing the condition of adjustment for obtaining correct and reproducible results is emphasised. The method gives vals. of abs. rates of migration of ions and may be applied to ascertain the changes taking place in different layers of the solutions at the boundary. As in the MacInnes method (A., 1929, 1390) the transference nos. can be obtained simultaneously. E. E. A.

**Breakdown and conductivity of anodically oxidised aluminium.** J. W. HOLST (Z. Elektrochem., 1936, 42, 138—143).—The breakdown potentials of the dried oxide layer in anodically oxidised

Al are found, in conformity with the results of Just and Betz (A., 1933, 555, 667), to differ widely according to the direction of the applied p.d. An explanation is afforded by the observation that the conductivity ( $\kappa$ ) of the oxide layer in the negative ( $\text{Al}^-$ ) direction  $>$  in the positive ( $\text{Al}^+$ ). Comparison of oxide layers when dry and when immersed in electrolyte solutions shows that  $\kappa$  does not depend on the electron concn. in the adjacent layers of Al and electrolyte. The experiments indicate that  $\kappa$  is determined by the migration of  $\text{H}^+$  and  $\text{OH}^-$  within the oxide layer. F. L. U.

**Oxido-reduction potential of reductone.** R. WURMSER, N. MAYER, and O. CRÉPY (J. Chim. phys., 1936, 33, 101—110; cf. A., 1934, 1072).—It has been shown spectrographically that reductone (I) forms a reversible oxidation-reduction system. The absorption max. shifts from 2650 to 2900 Å. when the  $p_{\text{H}}$  changes from 4 to 6 and (I) regenerated by reversible oxidation behaves identically. (I) is more stable in alkaline solutions whilst the product of oxidation is more stable in acid solutions. The normal potential of the system at different  $p_{\text{H}}$  vals. has been determined. R. S.

**Displacement of the oxidation-reduction potential on illumination of methylene-blue solutions containing iron.** H. HELLSTRÖM (Naturwiss., 1936, 24, 217; cf. A., 1935, 1087; this vol., 270).—The reduction-oxidation potential of the methylene-blue (I)— $\text{Fe}^{2+}$  system decreases reversibly when the system is illuminated. The potential depends on  $p_{\text{H}}$  in a manner similar to the fluorescence. In the system (I)—leuco-base in equal concns. no change of potential occurred on illumination. Addition of  $\text{K}_4\text{Fe}(\text{CN})_6$  in place of  $\text{Fe}^{2+}$  was ineffective. This further supports the view that there is combination between (I) and Fe, (I) being probably activated in the compound. A. J. M.

**Diffusion potential.** Y. KAUKO and V. MANTERE (Suomen Kem., 1936, 9, B, 9—12).—The e.m.f. of the electrode  $\text{H}_2|0.1\text{N-HCl}|0.1\text{N-KCl}$  in combination with the  $\text{Hg}_2\text{Cl}_2$  electrode is unaffected by movement of the  $0.1\text{N-HCl}$  into the  $0.1\text{N-KCl}$  or by stirring of the latter. Investigation of the diffusion potentials of a series of cells shows that in previous work (A., 1935, 1321) the error from this source is small and can be calc. At greater ionic concns. the calculation is uncertain. R. S.

**Preparation and investigation of oxide cathodes of colloid structure.** E. PATAI and Z. TOMASCHEK (Kolloid-Z., 1936, 74, 253—265).—Alkaline-earth oxide cathodes have been prepared by electrophoretic deposition from colloidal hydrosols of the corresponding carbonates under controlled conditions. The influence of composition, concn., c.d., temp., and cathode material on the structure and emissive properties of the cathodes has been investigated. E. S. H.

**Influence of colloids on electrode processes.** V. J. VOLKOV (Trans. Kirov Inst. Chem. Tech. Kazan, 1935, No. 4—5, 57—79).—Anode polarisation is absent in the electrolysis of  $0.5\text{—}1\text{N-ZnSO}_4$  in presence of gelatin, ovalbumin, or agar, whilst

cathode polarisation rises to a max., and then falls with increasing concn. of these colloids. The rise is ascribed to the binding of Zn by the colloids, with consequent diminution in its ionic concn., whilst the subsequent fall is due to increase in  $[\text{Zn}^{2+}]$ , owing to binding of  $\text{H}_2\text{O}$  by the colloids. R. T.

**Mineral electrodes. III. Adsorption of calcium by gum arabic.** H. J. C. TENDELOO (Rec. trav. chim., 1936, 55, 227—230; cf. A., 1935, 706).— $\text{CaF}_2$  (fluorite) electrodes can, with suitable precautions, be used to measure  $p_{\text{Ca}}$ . The potential is not affected by changes of acidity. Measurement of the  $p_{\text{Ca}}$  of solutions of gum arabic containing varying amounts of Ca shows that a part of the Ca is adsorbed, the solution behaving as a Ca buffer. F. L. U.

**Cathode effect in electrolysis of cadmium salts.** O. KUDRA (Z. physikal. Chem., 1936, 175, 377—382; cf. B., 1935, 857).—If the c.d. at the cathode,  $\sigma$ , is kept const. the deposit of Cd, which is initially smooth and white, suddenly becomes black and spongy when electrolysis has proceeded for a time  $\tau$ , which depends on the concn. of the solution,  $c$ , according to  $\log c = \alpha \log \sigma + \beta \log \tau + \gamma$ , where  $\alpha$ ,  $\beta$ , and  $\gamma$  are consts. which depend on the salt being electrolysed. Probably the formation of a spongy deposit is promoted by the presence in it of oxide, which agrees with the observation that the effect is the more marked the greater is the oxidising power of the salt anion. R. C.

**Polarisation phenomena at the ferric-ferrous electrode.** W. L. H. MOLL (Z. physikal. Chem., 1936, 175, 353—358).—In the electrolysis of a mixed solution of a  $\text{Fe}^{\text{II}}$  and a  $\text{Fe}^{\text{III}}$  salt with a fresh electrode of Pt or Au there is no overvoltage, showing that the change in ionic charge occurs without any considerable hindrance. If the electrode has been in contact with the solution for some time, however, it exhibits a continually increasing chemical polarisation, which can be eliminated by polarising the electrode cathodically or anodically so far that gas is evolved. R. C.

**Production of aluminium by electrolysis of fused cryolite and aluminium oxide.** P. DROSSBACH (Z. Elektrochem., 1936, 42, 144—147).—Decomp. potentials of  $\text{NaF}$  and  $\text{AlF}_3$  (cf. A., 1934, 1078) are recalcd. The vals. at  $950^\circ$  are:  $\text{NaF}$  4.4—4.6,  $\text{AlF}_3$  3.4—3.7 volts. F. L. U.

**Neutralisation of aqueous solutions of metaphosphimic and di-imidotriphosphoric acids.** A. M. DE FICQUELMONT (Compt. rend., 1936, 202, 848—850).—Variations of conductance during titration by  $\text{NaOH}$  have been determined for  $N/3000$  solutions of di-imidotriphosphoric (I), tri- (II) and tetra-metaphosphimic (III) acids. (I) and (II) are tribasic, but (III) has a fourth ionisable H with an ionisation const. which is much  $<$  that of the other three, but of the same order as that of the second  $\text{H}^+$  of  $\text{H}_3\text{PO}_4$ . M. S. B.

**Devaux's observation of the modification of a film of copper sulphide by means of copper.** J. CAYREL (Compt. rend., 1936, 202, 926—929; cf. this vol., 435).—When a piece of Cu is placed in con-

tact with the film and with a  $\text{CuSO}_4$  solution Cu is deposited. The e.m.f. of the cell  $\text{CuS}|10\% \text{ aq. CuSO}_4|\text{Cu}$  is 0.2 volt ( $15^\circ$ ). The thickness of the Cu film is independent of the current, extent of the film, and  $[\text{CuSO}_4]$ . H. J. E.

Recent theoretical and experimental researches on unimolecular reactions. A. LALLANDE (Bull. Soc. chim., 1936, [v], 3, 521—537).—A lecture.

Chemical reaction in ionised gases. K. G. EMELEUS and R. W. LUNT (Nature, 1936, 137, 404).—The assumption that, in the reactions in ionised gases, one or more of the reacting atoms or mols. react while ionised is unnecessary. The kinetics of reactions in discharges can be accounted for on the assumption that the reacting particles are all neutral. Reactions appear to be related only incidentally to the conductivity of the gas. L. S. T.

Ignition of hydrogen-chlorine gas [mixtures] by high-velocity electrons. A. E. MALINOVSKI and K. A. SKRINNIKOV (Physikal. Z. Sovietunion, 1935, 8, 289—293; cf. A., 1935, 1212).— $\text{H}_2\text{—Cl}_2$  mixtures are not exploded by high-velocity electrons in concns. up to  $0.6 \times 10^5$  per c.c. R. S.

Rate of reaction of deuterium with hydrogen chloride. P. GROSS and H. STEINER (J. Chem. Physics, 1936, 4, 165—169).—The reaction  $\text{D}_2 + \text{HCl} = \text{HD} + \text{DCl}$  between  $765^\circ$  and  $843^\circ$  abs. is bimol. and mainly homogeneous over a range of  $\text{D}_2$  and HCl partial pressures of 80—300 mm. Conditions appear to change at pressures below 50 mm. Measurements made in packed vessels indicate that a wall reaction takes place also, but to an extent of  $> 15\%$  at the lowest temp. The activation energy is  $52.1 \text{ kg.-cal.}$  and the homogeneous bimol. const. is  $k = 6.27 \times 10^{13} T^{0.5} e^{-26,200/T} \text{ mole}^{-1} \text{ c.c. sec}^{-1}$ . Deviations observed at the highest temp.,  $843^\circ$  abs., are probably due to at. reactions. M. S. B.

Reactions involving hydrogen molecules and atoms. J. HIRSCHFELDER, H. EYRING, and B. TOPLEY (J. Chem. Physics, 1936, 4, 170—177).—The best potential energy surface for three H atoms has been constructed, and from it the rates of all the possible reactions between H and D have been calc. by means of the general theory of abs. rates. The agreement with experimental data is satisfactory. M. S. B.

Absolute rates of reaction of hydrogen with the halogens. A. WHEELER, B. TOPLEY, and H. EYRING (J. Chem. Physics, 1936, 4, 178—187).—The statistical-mechanical method is applied to the calculation of the abs. rates of reaction of I,  $\text{Cl}_2$ , and Br with  $\text{H}_2$ , HD, and  $\text{D}_2$ . The correct relative rates are obtained and, in agreement with experiment, the potential surfaces indicate that H is much more reactive than D. M. S. B.

Rate of elementary reactions of hydrogen and deuterium. L. FARKAS and E. WIGNER (Trans. Faraday Soc., 1936, 32, 708—723; cf. this vol., 32).—Velocity coeffs. of the following reactions are calc. on the basis of recent theory (A., 1932, 343; 1933, 30):  $\text{H} + \text{H}_2 \rightarrow \text{H}_2 + \text{H}$ ;  $\text{D} + \text{D}_2 \rightarrow \text{D}_2 + \text{D}$ ;  $\text{D} + \text{H}_2 \rightarrow \text{DH}$

$+ \text{H}$ ;  $\text{H} + \text{D}_2 \rightarrow \text{HD} + \text{D}$ . The vals. obtained are discussed in relation to available experimental data. F. L. U.

Para-hydrogen conversion on glass. A. M. MAGID and S. Z. ROGINSKI (J. Phys. Chem., U.S.S.R., 1934, 5, 1278—1282).—The para-ortho conversion of H on soda-glass at  $160\text{—}320^\circ/20\text{—}200 \text{ mm.}$  is a first-order reaction (energy of activation 17000 g.-cal. per mole). Only about 1% of the sufficiently activated mols. striking the walls undergo conversion. On Pyrex and Mo-glass the reaction is much more rapid. On the latter it is rapid at  $< 200^\circ$ . CH. ABS. (e)

Kinetics of the thermal chain reaction in mixtures of hydrogen and oxygen. M. PRETTRE (J. Chim. phys., 1936, 33, 189—218; cf. this vol., 32).—At  $500\text{—}600^\circ$  glass walls adsorb considerable amounts of  $\text{H}_2$  and  $\text{H}_2\text{O}$  with a low velocity which increases with rise of temp., and these adsorbed gases, respectively, decrease and increase the velocity of reaction between  $\text{H}_2$  and  $\text{O}_2$ . The  $\text{H}_2$  probably increases the no. of centres of chain formation, but also breaks the chains, whereas  $\text{H}_2\text{O}$  promotes their branching. A KCl surface, which is less adsorbent than glass, diminishes the no. of centres of chain formation, and also breaks the chain more than a glass surface. Near ignition conditions at  $400\text{—}700 \text{ mm.}$ , the velocity of reaction no longer obeys Arrhenius' law and rises increasingly rapidly with rise of temp., indicating the occurrence of a homogeneous reaction with frequently branched chains, which is responsible for ignition. J. W. S.

Theory of the chamber process. Mechanism and kinetics of oxidation of  $\text{SO}_2$  by nitrogen dioxide in the gas phase. I. N. KUZMINICH, E. J. TURCHAN, and M. S. ARCHIPOVA (Z. anorg. Chem., 1936, 226, 310—320; cf. A., 1935, 308).— $\text{SO}_2$  is oxidised by  $\text{NO}_2$  in the gas phase at  $80^\circ$  in the absence of liquid. Increasing the amount of  $\text{H}_2\text{O}$  vapour above 0.1 vol.-% does not increase the speed of reaction, whilst drying with  $\text{P}_2\text{O}_5$  diminishes it to about  $\frac{1}{3}$  of the normal val. The reaction is bimol. Velocity coeffs. are given for the range  $65\text{—}150^\circ$ . The velocity depends on the shape of the reaction vessel and decreases with decreasing rate of flow in a manner consistent with a chain mechanism.  $\text{H}_2\text{O}$  acts as a homogeneous catalyst. F. L. U.

Reaction of nitric oxide with hydrogen and with deuterium. C. N. HINSHELWOOD and J. W. MITCHELL (J.C.S., 1936, 378—384).—A reinvestigation at  $801^\circ$  of the reaction between  $< 900 \text{ mm.}$  of  $\text{H}_2$  and  $< 500 \text{ mm.}$  of NO in  $\text{SiO}_2$  bulbs affords no evidence of long reaction chains and shows that the proportion of heterogeneous reaction is much  $<$  was previously supposed (A., 1926, 579). When  $[\text{H}_2]$  is  $< 100 \text{ mm.}$ , the initial rate of reaction decreases more rapidly than corresponds with the linear relation, at const.  $[\text{NO}]$ , between velocity and  $[\text{H}_2]$ . The reaction, although homogeneous and essentially termol., probably involves binary collision complexes of different lives. The hypothesis leads to an equation which accords with the data. With  $\text{H}_2$ , the rate of change of pressure (mm. per 100 sec.) is  $[\text{NO}]^2[\text{H}_2]\{1.0 + 30/(1 + 8.0[\text{NO}]) + 11/(1 + 3.4[\text{H}_2])\}$  and with  $\text{D}_2$ ,  $[\text{NO}]^2[\text{D}_2]\{0.7 + 12.5/(1 + 8.0[\text{NO}]) + 7.7/(1 + 2.4[\text{D}_2])\}$

(concn. unit, 100 mm.); the differences between the velocities are ascribed chiefly to the different mol. speeds. The temp. coeff. of the  $H_2$  reaction at 700—825° leads to the activation energy 47 kg.-cal.

J. G. A. G.

**Reactions between sodium vapour and volatile polyhalides. Velocities and luminescences.** W. HELLER and M. POLANYI (Trans. Faraday Soc., 1936, 32, 633—642).—See A., 1935, 150. F. L. U.

**Pressure and ionisation in the front of the explosion wave in the pre-detonation period.** A. E. MALINOVSKI, B. I. NAUGOLNIKOV, and K. T. TRATSCHENKO (Physikal. Z. Sovietunion, 1935, 8, 536—540).—A method for registering simultaneously the flame velocity, the spreading of the compression wave, and the ionisation at the front of the wave when a mixture of  $C_2H_2$  and air was exploded, is described. The conductivity at the explosion wave-front was determined by a method similar to that of Kirkby (A., 1931, 688) and the pressure changes by Töppler's method. A. J. M.

**Kinetics of the decomposition of ethyl ether at high pressures.** E. W. R. STEACIE, W. H. HATCHER, and S. ROSENBERG (J. Chem. Physics, 1936, 4, 220—223).—A more accurate investigation of the decomp. of  $Et_2O$  at 426° and pressures up to 260 atm. confirms previous approx. data (A., 1934, 1179). The rate of reaction increases with pressure throughout the range in which it was examined. The results are explicable, qualitatively, on the basis of the Rice-Herzfeld free radical mechanism, but the reaction is too complicated for quant. comparison with theory. M. S. B.

**Decomposition of ethylamine and diethylhydrazine.** H. A. TAYLOR and J. G. DITMAN (J. Chem. Physics, 1936, 4, 212—218).—The decomp. of  $NH_2Et$  has been reinvestigated (cf. A., 1931, 175). The reaction is now shown to be bimol., giving  $(NH_2Et)_2$  (I) and  $H_2$  without vol. change. (I) subsequently decomposes by a first-order chain reaction at a rate < that of the first reaction. This mechanism accounts for the induction period and its rapid variation with temp. and pressure. M. S. B.

**Decomposition of methyl nitrite at high pressures.** E. W. R. STEACIE and S. ROSENBERG (J. Chem. Physics, 1936, 4, 223).—Measurements of the decomp. of  $MeO\cdot NO$  at high pressures indicate that, within a rather large experimental error, there is no appreciable increase in the rate of decomp. on changing the pressure from 65 cm. to 35 atm. The previous conclusion that the reaction is unimol. (A., 1935, 938) is confirmed. M. S. B.

**Homogeneous unimolecular decomposition of gaseous alkyl nitrites. V. Decomposition of methyl nitrite at low pressures.** E. W. R. STEACIE and D. S. CALDER (J. Chem. Physics, 1936, 4, 96—99).—Measurements of the rate of decomp. of  $MeO\cdot NO$  at pressures of 0.005—5.0 cm. and 210—240° have been made in packed and empty vessels. The reaction is about 5% heterogeneous at 1.5 cm. initial pressure and about 15% at 0.05 cm. The average val. of the activation energy is 36,100 g.-cal. The results are in good agreement with previous data at high

pressures (A., 1934, 1312). The fall in rate with diminishing pressure can be accounted for by Rice and Ramsperger's theory on the assumption of a mol. diameter of  $5.0 \times 10^{-8}$  cm. and 13 degrees of freedom. M. S. B.

**Thermal decomposition of divinyl ether.** H. A. TAYLOR (J. Chem. Physics, 1936, 4, 116—120).—The thermal decomp. of divinyl ether has been studied at 460—500°/30—1000 mm. The reduction in velocity at low pressures by increasing the surface of the reaction vessel, or at high pressures by adding  $N_2$ , the variation of temp. coeff. with pressure, and the induced decomp. with azomethane indicate a chain reaction in which the chains are broken on the walls at low and in the gas phase at high pressures. The overall order of the reaction at high pressures is 1.5. M. S. B.

**Influence of pressure of the surrounding gas on the luminosity accompanying the detonation of explosives.** A. MICHEL-LÉVY and H. MURAOUR (Compt. rend., 1936, 202, 755—757).—The transmission of detonation from one  $PbN_6$  granule to the next becomes increasingly difficult as the pressure ( $p$ ) of the surrounding gas is increased. At the same  $p$  it occurs more readily in A than in  $CO_2$ . With increasing  $p$  the deposit of Pb became more localised. At vals. of  $p > 20$  mm. a diffuse luminosity was observed at distances  $> 40$  cm. from the explosive. This was attributed to a shock wave. H. J. E.

**Practical rule permitting the interpretation of certain reactions of organic chemistry from the electronic point of view.** P. CARRÉ (Compt. rend., 1936, 202, 740—742; cf. this vol., 453).—The difference in reactivity of directly bound elements corresponds with a difference in polarity, which increases with the electronic displacement. Examples are discussed. H. J. E.

**Bimolecular reactions in solution.** C. N. HINSHELWOOD and C. A. WINKLER (J.C.S., 1936, 371—377).—Theoretical. The transition-state method does not supersede the collision method for treating bimol. reactions. Existing data for series of bimol. reactions in solution lead to vals. of the probability factor between  $P=1$  and  $P=10^{-8}$ , where (no. of mols. reacting) =  $PZe^{-E/RT}$  and  $Z$  is the no. of collisions. The factors affecting  $P$  are discussed, and it is shown, by assigning plausible magnitudes to each effect, that the whole range of observed behaviour can be explained, at least qualitatively, in terms of (i) the orientation of the mols. at collision, (ii) the phase of vibration at which the linkings rupture, (iii) steric hindrance, and (iv) solvent effects. J. G. A. G.

**Kinetics of the oxidation of nitrites with nitric acid.** A. F. POROVITSCH (Chimstr., 1935, 7, 202—205).—The reaction is bimol. in aq. solution, the temp. coeff. at 20—80° being given by  $\log k = 11.77 - 3767/T'$ . CH. ABS. (c)

**Kinetics and mechanism of reaction of ferrous ion with nitrous and nitric acids.** E. SCHRÖER (Z. physikal. Chem., 1936, 176, 20—47).— $Fe^{++}$  does not react with  $NO_2$  or  $HNO_3$ , but only with  $NO$ , the rate being given by  $d[Fe^{++}]/dt = k'[HNO_2]^2[Fe^{++}]/[NO]$ . Here  $k'$  is the product of a velocity coeff. by  $\sqrt{(K_1K_2)}$ .

where  $K_1$  and  $K_2$  are the equilibrium consts. of  $4\text{HNO}_2 \rightleftharpoons \text{N}_2\text{O}_4 + 2\text{NO} + 2\text{H}_2\text{O}$  and  $\text{N}_2\text{O}_4 \rightleftharpoons 2\text{NO}_2$ , respectively. The reaction mechanism is  $2\text{HNO}_2 \rightleftharpoons \text{NO}_2 + \text{NO} + \text{H}_2\text{O}$ ,  $\text{Fe}^{++} + \text{NO}_2 \rightarrow \text{Fe}^{+++} + \text{NO}_2'$ ,  $\text{NO}_2' + \text{H}^+ \rightleftharpoons \text{HNO}_2$ . The energy of activation of the second of these is small or zero. Reaction begins normally, but after a time the velocity increases considerably and falls only towards the end. The explanation is that the NO formed retards the reaction because it depresses  $[\text{NO}_2]$  and at first the NO remains almost entirely in solution combined with the  $\text{Fe}^{++}$  salt, but as  $[\text{Fe}^{++}]$  falls the distribution ratio of the NO changes in favour of the gaseous phase. The velocity is independent of  $[\text{Fe}^{+++}]$ , and is influenced by  $[\text{H}^+]$  only in so far as this affects the dissociation of the  $\text{HNO}_2$ . The velocity-time relations for the reaction between  $\text{Fe}^{++}$  and  $\text{HNO}_3$  catalysed by  $\text{HNO}_2$  are similar to the above, but here the NO is removed by  $\text{NO}_2 + \text{NO} + \text{H}_2\text{O} \rightarrow 2\text{HNO}_2$ ; the amount of  $\text{HNO}_2$  which must be added to effect complete reactions decreases with rising temp. and is zero above  $65^\circ$  (cf. A., 1932, 242).

R. C.

**Hydrolysis of starch by hydrogen peroxide and ferrous sulphate.**—See this vol., 594.

**Kinetic study of addition of methyl hypobromite to stilbene.**—See this vol., 600.

**Rates of alcoholysis of triarylmethyl chlorides.** A. C. NIXON and G. E. K. BRANCH (J. Amer. Chem. Soc., 1936, 58, 492—498).—The kinetics of reaction of *p*-monosubstituted  $\text{CPh}_3$  chlorides with  $\text{EtOH}$  in  $\text{Et}_2\text{O}$  solution at  $25^\circ$  has been studied by electrical conductivity determinations. The heats of activation of all the reactions have been determined. The influence of substituent groups is discussed.

E. S. H.

**Heats of activation of the related reactions involved when *l*-bromosuccinic acid is treated with chloride ion.** A. R. OLSON and F. A. LONG (J. Amer. Chem. Soc., 1936, 58, 393—398).—The heats of activation and the collision factors for the 6 related reactions (cf. A., 1934, 847) have been determined at  $25$ – $88^\circ$ . The collision factors of the four binol. reactions are of the same order of magnitude as those calc. from kinetic theory.

E. S. H.

**Oxidation of cyclic compounds by potassium permanganate.** C. N. HINSHELWOOD and C. A. WINKLER (J.C.S., 1936, 368—370).—The velocity coeffs. at  $0$ – $80^\circ$  lead to the following activation energies of the oxidations using  $0.1N\text{-KMnO}_4$  and  $0.02N\text{-H}_2\text{SO}_4$ : picric acid (I) 12,200 g.-cal.,  $\text{BzOH}$  (II) 12,700, 2:4:6-trinitro-3-methylnitroaminophenol (III) 13,100, trinitro-*m*-cresol (IV) 14,600, 2:4-dinitrophenol (V) 15,300, 2:6-dinitrophenol (VI) 15,600, and  $m\text{-C}_6\text{H}_4(\text{NO}_2)_2$  (VII) 17,300. The primary ring-breaking step is an interaction of  $\text{MnO}_4^-$  with a mol. (or ion) of the org. compound. (I), (III), and (IV) react as ions, (II), (V), and (VII) react as mols., and (VI) reacts chiefly as mols. The structure of the mols. has very sp. effects on the probability factor.

J. G. A. G.

**Velocity of the exchange reaction of the hydrogen atom between sugar and water.** M. HARADA and T. TITANI (Bull. Chem. Soc. Japan, 1936, 11, 55—56).—By adding  $\text{D}_2\text{O}$  to neutral, acid, or alkaline aq.

q q

solutions of glucose and distilling portions at intervals, it is concluded from the absence of any difference in the  $d$  of the distillates that the exchange of H between glucose and  $\text{H}_2\text{O}$  is rapid and that equilibrium is attained in  $< 1$  min.

C. R. H.

**Mutarotation of glucose in  $\text{H}_2\text{O}$ – $\text{D}_2\text{O}$  mixtures.** W. H. HAMILL and V. K. LA MER (J. Chem. Physics, 1936, 4, 144—145).—If the changes in velocity with  $\alpha$ -*D*-glucose (I) in heavy  $\text{H}_2\text{O}$  are ascribed solely to the replacement of H by D in that position in the (I) mol. involved in the mutarotation, viz., in the OH on the terminal C, and not, as before (A., 1935, 309), to the relative concns. of  $\text{H}_2\text{O}$ ,  $\text{HDO}$ , and  $\text{D}_2\text{O}$ , an exchange const.,  $K = [\text{D} - (\text{I})] \cdot [\text{H}_2\text{O}] / [\text{H} - (\text{I})] \cdot [\text{HOD}]$  may be determined from previous experimental data. The average val. of  $K$  is 0.83, in exact agreement with that for tetramethyl- $\alpha$ -*D*-glucose found directly from exchange experiments (A., 1935, 1212), but not with that for (I), 0.69, which is, however, an average val. for the 5 possible variations due to the 5 exchangeable H in the (I) mol. The correct explanation may be between the two extreme views advanced.

M. S. B.

**Reaction rates of propionic and acetic propionic anhydrides.** E. S. BARR and E. K. PLYLER (J. Chem. Physics, 1936, 4, 90—92).—The velocities of hydrolysis of propionic (I) and acetic propionic (II) anhydrides in  $\text{H}_2\text{O}$  have been determined at  $27^\circ$  by the rate of change in intensity of the infra-red spectra (cf. this vol., 34). The reactions are apparently unimol., but the val. of the coeff. is influenced by the concn. of the anhydride and  $\propto [\text{H}_2\text{O}]$ , approx. The val. for (II) is about double that for (I).

M. S. B.

**Mechanism of aromatic side-chain reactions, etc. IV. (Addendum.) Velocity of the reaction between *o*-nitrobenzyl bromide and pyridine.** J. W. BAKER (J.C.S., 1936, 399—400; cf. this vol., 195).—The data indicate that the enhanced reaction rate observed with 2:4- $(\text{NO}_2)_2\text{C}_6\text{H}_3\cdot\text{CH}_2\text{Br}$  results from augmented electron attraction due to two  $\cdot\text{NO}_2$  radicals suitably oriented to the side-chain (cf. Bennett, Chem. and Ind., 1935, 1008).

J. G. A. G.

**Adsorption velocity of active carbon.** M. TARLÉ (Bull. Mukden Arsenal, No. 8, 11 pp.).—The adsorption of  $0.1N\text{-KMnO}_4$  by active C is a unimol. surface reaction, the active area of the C being inversely  $\propto$  the  $\text{KMnO}_4$  removed by adsorption at any given time.

Ch. Abs. (e)

**Oxidation of metals. III. Kinetics of the oxidation of molten tin.** L. L. BIRCHUMSHAW and G. D. PRESTON (Phil. Mag., 1936, [vii], 21, 686—697).—The rate of oxidation ( $v$ ) of molten Sn rises rapidly at  $400$ – $800^\circ$ , but at any given temp.  $v$  is found to vary even with similar samples. The parabolic law is not obeyed, especially at high and low  $\text{O}_2$  pressures, so  $v$  is controlled by a factor other than progressive increase in film thickness. It is suggested that the orientation of the crystals in the oxide film is a controlling influence in determining the rate of oxidation.

J. W. S.

**Oxidation of metallic magnesium at high temperature.** Y. SUZUKI (Bull. Inst. Phys. Chem. Res. Japan, 1936, 15, 147—165).—The increase in wt.

of Mg at about 560° in air, plotted by means of a thermobalance, was a linear function of time. The initial atm. corrosion film and the oxide film produced had no measurable resistance to the reaction. Only a trace of nitride was detected. N. M. B.

**Dust explosions.** W. P. M. MATLA (Rec. trav. chim., 1936, 55, 173—191; cf. B., 1935, 1024).—The reaction regions of mixtures of air with dusts of Al, dextrin, Ph<sub>2</sub>, anthracene, and picric acid have been determined, using spark ignition. The quenching effect of added shale, stone, fuller's earth, bone C, Fe<sub>2</sub>O<sub>3</sub>, C<sub>2</sub>Cl<sub>6</sub>, MnO<sub>2</sub>, hopcalite, and various inorg. K and Na salts depends partly on the nature of the combustible dust. With anthracene the order of effectiveness is: KF > KNO<sub>3</sub> > KI > KBr > KCl; NaF > NaI > NaNO<sub>3</sub> > NaBr > NaCl; KCl > C<sub>2</sub>Cl<sub>6</sub> > NaCl. With dextrin, KClO<sub>3</sub> > MnO<sub>2</sub> > Fe<sub>2</sub>O<sub>3</sub> > hopcalite. Fe<sub>2</sub>O<sub>3</sub> is more effective than KClO<sub>3</sub> with Al, whilst the reverse is true for picric acid. K salts are invariably more effective than the corresponding Na salts. The quenching effect of Fe<sub>2</sub>O<sub>3</sub> on different combustible dusts is in the order Al > dextrin > picric acid > Ph<sub>2</sub>. There is no parallelism between the quenching power and the sp. heat of the quenching material, and the cause of the effect is at present obscure. F. L. U.

**Reduction of iron oxides by gaseous reducing agents.** II. **Rate of reduction of magnetic iron oxide by hydrogen.** G. I. TSCHUFAROV and B. D. AVERBUCH (J. Phys. Chem. U.S.S.R., 1934, 5, 1292—1298; cf. this vol., 166).—Natural samples and those prepared from piano wire show autocatalytic effects on reduction. The initial rate of reduction increased with the temp. (350—900°), but above 600° the rate decreases quickly with time, and the curve for 800° crosses those for 400° and 600° at approx. 70% reduction. Above 800° this effect is less marked. FeO is formed as an intermediate. The max. rates were observed at 600°. CH. ABS. (e)

**Oxidation of aromatic hydrocarbons at high pressures.** I—III.—See this vol., 599.

**Hydrolysis in the vapour phase.** S. YAMASAKI (Bull. Chem. Soc. Japan., 1936, 11, 43—44).—Using HCl or I as a catalyst, EtOAc is only slightly hydrolysed at 200°. The catalytic effect of gas ions, obtained by exposing the reaction mixture to X-rays, is also negligible. C. R. H.

**Thermal decomposition of ethylene oxide and an induced acetaldehyde decomposition.** C. J. M. FLETCHER (J. Amer. Chem. Soc., 1936, 58, 534—535).—The production of free radicals and aldehydes at 400°, followed by decomp. of the aldehydes, is suggested as a mechanism of reaction. E. S. H.

**Kinetics of polymerisation processes.** II. G. GEE. III. **Effects of catalysts and inhibitors.** G. GEE and E. K. RIDEAL (Trans. Faraday Soc., 1936, 32, 656—666, 666—674; cf. A., 1935, 1080).—II. Theoretical. In polymerisations in which chain-breaking occurs through spontaneous deactivation or deactivation by a special type of collision with the monomer, the fraction polymerised before the max. velocity is attained varies from 0 with strong deactivation to  $\frac{1}{2}$  with no deactivation and zero steric

factor, and finally approaches 0.5 for large steric factors. The theory is applied to actual examples.

III. All experimental observations can be explained by assuming that the action of a catalyst depends on its forming a reactive complex. The assumption that the effect of an inhibitor is to diminish the velocity of a polymerisation process and the chain length of the polymeride in the same ratio is approx. valid only in the early stages of the reaction. F. L. U.

**Ozone as oxidising catalyst.** X. **Ozonisation of ferrous ammonium sulphate and of stannous chloride.** E. BRINER and (MLLE.) B. BEVER (Helv. Chim. Acta, 1936, 19, 367—369; cf. A., 1935, 1328).—Ozonised O<sub>3</sub> acts on aq. Fe(NH<sub>4</sub>)<sub>2</sub>(SO<sub>4</sub>)<sub>2</sub>, thus:  $2\text{Fe}(\text{NH}_4)_2(\text{SO}_4)_2 + \text{O}_3 + \text{H}_2\text{SO}_4 = \text{Fe}_2(\text{SO}_4)_3 + (\text{NH}_4)_2\text{SO}_4 + \text{H}_2\text{O} + \text{O}_2$ . The autoxidation is  $\approx 1-2\%$ . Aq. SnCl<sub>2</sub> containing 10% of HCl reacts thus:  $3\text{SnCl}_2 + 6\text{HCl} + \text{O}_3 = 3\text{SnCl}_4 + 3\text{H}_2\text{O}$ . The action of O<sub>3</sub> is indirect, i.e., it oxidises the HCl in presence of SnCl<sub>2</sub>, although it has no effect in its absence. Autoxidation amounts to 8—12%. F. L. U.

**Interpretation of the immeasurably fast reaction in a solution containing oxalic acid, permanganate ion, and manganous ion.** M. J. POLISSAR (J. Chem. Educ., 1936, 13, 40—42).—The reduction of MnO<sub>4</sub>' with Mn<sup>++</sup> in acid solution is autocatalytic. The reaction is catalysed by MnO<sub>2</sub>. Skrabal's mechanism for the reaction between MnO<sub>4</sub>', Mn<sup>++</sup>, and C<sub>2</sub>O<sub>4</sub>' in acid solution needs modification. The assumption of a rapid equilibrium between MnO<sub>4</sub>', Mn<sup>++</sup>, Mn<sup>+++</sup>, and Mn<sup>++++</sup> explains this reaction, and also the accelerating effect of other complex-forming ions on the Mn<sup>++</sup>-MnO<sub>4</sub>' reaction. L. S. T.

**Organic catalysts.** XIII.—See this vol., 589.

**Catalytic action of copper oxide on the combustion of hydrogen.** [New catalysts.] G. TERESCHI (Gazzetta, 1936, 66, 57—64).—If the catalytic action of CuO on the combustion of H<sub>2</sub> is due to the reactions:  $\text{CuO} + \text{H}_2 = \text{H}_2\text{O} + \text{Cu}$ , and  $2\text{Cu} + \text{O}_2 = 2\text{CuO}$ , and if O<sub>2</sub> is in great excess,  $-d[\text{H}_2]/dt = k_1[\text{H}_2]$ . If O<sub>2</sub> is not in great excess, but  $[\text{H}_2] \gg 2[\text{O}_2]$ , the catalyst will be partly reduced, and  $-d[\text{H}_2]/dt = k_1'[\text{H}_2]$ , where  $k_1' < k_1$ . The first approximation  $k_1' = k_1 - a[\text{H}_2]/[\text{O}_2]$  has been tested experimentally at 151° for  $[\text{H}_2]/[\text{O}_2] = 0.18, 1, \text{ and } 2$ , and graphs obtained agreeing with the integrated equations and the val.  $k_1 = 6.10 \times 10^{-4}$ ,  $a = 5.14 \times 10^{-5}$ .

$\text{CuO} + \text{Al}_2\text{O}_3$ , prepared by simultaneous pptn., is an unsatisfactory catalyst.  $\text{CuO} + \text{MgO}$ , obtained from MgO and CuSO<sub>4</sub>, has increased activity if MgSO<sub>4</sub> is well washed out.  $\text{CuO} + \text{CaO}$ , and  $\text{CuO} + \text{BaO}$ , obtained similarly, and dried at 90—100°, are very much more active as catalysts than the CuO ordinarily used. E. W. W.

**Influence of different metals and metallic oxides on the decomposition of carbon monoxide.** W. BAUKLOH and G. HIEBER (Z. anorg. Chem., 1936, 226, 321—332).—The catalytic effects of Fe<sub>2</sub>O<sub>3</sub>, Fe<sub>3</sub>O<sub>4</sub>, Fe, Co<sub>3</sub>O<sub>4</sub>, Co, Ni<sub>2</sub>O<sub>3</sub>, NiO, Ni, Cr<sub>2</sub>O<sub>3</sub>, Cr, Mn<sub>3</sub>O<sub>4</sub>, Mn, Al<sub>2</sub>O<sub>3</sub>, Al, ZnO, Zn, and CuO on the decomp. of CO have been studied at 350—850°. The results indicate that the decomp. is cata-

lysed by reduced metal, and not by the oxides, the activity of easily reducible oxides being  $>$  that of the metal, but decreasing as the active centres become coated with C. Oxides which are difficult to reduce show little or no activity. J. W. S.

**Vanadium catalysts for the manufacture of sulphuric acid.**—See B., 1936, 315, 316.

**Platinised nickel gauze for contact oxidation of ammonia.**—See B., 1936, 316.

**Effect of magnesia on the synthesis of tricalcium silicate.** S. KONDO and M. HIGUCHI (J. Japan. Ceram. Assoc., 1935, 43, 273—280).—Mixtures of 100 parts of  $3\text{CaO} + \text{SiO}_2$  and 0—6 parts of  $\text{MgO}$  were heated for 90 min. at  $1500^\circ$ . Formation of  $\text{Ca}_3$  silicate was accelerated by  $\text{MgO}$ . Pulverisation and reheating also favoured its formation.

CH. ABS. (e)

**Catalytic decomposition of bleaching powder liquor.**—See B., 1936, 368.

**Effect of water vapour on the rate of interaction between iodine and metals (iron and copper).** A. V. SOLOVIEV (Compt. rend. Acad. Sci. U.R.S.S., 1935, 4, 185—188; cf. A., 1931, 698).—The interaction between I and Fe or Cu in presence of different  $[\text{H}_2\text{O}]$  has been studied. The rate decreases with time, but not always according to a parabolic law. R. S.

**Interaction between aluminium and iodine in an air atmosphere of different humidities.** A. V. SOLOVIEV (Compt. rend. Acad. Sci. U.R.S.S., 1935, 4, 189—191).—The rate of reaction between I and Al is a max. at 6.18 and at 12.7 mm. of  $\text{H}_2\text{O}$  at  $15^\circ$ . Absorption of  $\text{H}_2\text{O}$  occurs as the reaction proceeds, resulting in an increase in the rate owing to electrochemical and chemical action. R. S.

**Properties and industrial application of catalysts.** O. KOSZTELITZ (Tech. Kurir, 1936, No. 3, 1—3; No. 4, 2—5).—A review. E. P.

**Catalytic combustion of methane.** I. W. DAVIES (Phil. Mag., 1936, [vii], 21, 513—531; cf. A., 1935, 455).—The temp. at which reaction between  $\text{CH}_4$  and  $\text{O}_2$  is initiated on a Pt wire is nearly  $1000^\circ$  at low  $[\text{CH}_4]$ , but the rate of heating of the wire is then rapid, whereas at high  $[\text{CH}_4]$  combustion begins at  $400^\circ$ , but the catalytic activity of the wire decreases rapidly with further rise of temp. With small quantities of  $\text{CH}_4$  and  $\text{H}_2$  in  $\text{O}_2$ , combustion of the  $\text{H}_2$  begins at  $200^\circ$ , whilst the  $\text{CH}_4$  remains inert up to about  $900^\circ$ . Hence the wire acts as a preferential catalyst for the combustion of  $\text{H}_2$  between  $200^\circ$  and  $900^\circ$ . These limits are reduced as the ratio  $[\text{CH}_4] : [\text{O}_2]$  is increased. The reaction between  $\text{CH}_4$  and  $\text{O}_2$  probably involves adsorption of both reactants, whereas that between  $\text{H}_2$  and  $\text{O}_2$  involves adsorbed  $\text{O}_2$  and  $\text{H}_2$  from the gas phase. J. W. S.

**Preparation and catalytic oxidation of pure amorphous carbon.**—See B., 1936, 305.

**Phosphoric acid as catalyst for alkylation of aromatic hydrocarbons.**—See B., 1936, 309.

**Properties of zinc-chromium catalyst for methyl alcohol synthesis.**—See B., 1936, 309.

**Catalytic decomposition of alcohols.** P. J. IVANNIKOV and E. J. GAVRILOVA (J. Chem. Ind. Russ., 1935, 12, 1256—1260).—The process of catalytic ( $\text{CuO} + 0.1\% \text{ThO}_2$ ) conversion of  $\text{EtOH}$  (I) into  $\text{EtOAc}$  (II) at  $220$ — $450^\circ$  (optimum  $350^\circ$ ) consists of the reactions  $(\text{I}) \rightarrow \text{MeCHO}$  (III) +  $\text{H}_2$ ;  $2(\text{III}) \rightarrow (\text{II})$ ;  $(\text{III}) + 2(\text{I}) \rightarrow \text{CHMe}(\text{OEt})_2$  (IV) +  $\text{H}_2\text{O}$ ;  $(\text{II}) + \text{H}_2\text{O} \rightleftharpoons (\text{I}) + \text{AcOH}$  (V);  $(\text{III}) + \text{H}_2\text{O} \rightarrow (\text{V}) + \text{H}_2$ ;  $(\text{IV}) + (\text{V}) \rightarrow (\text{II}) + (\text{I}) + (\text{III})$ . Production of (II) through the intermediary of (IV) is the dominant reaction at  $300$ — $350^\circ$ . The reactions take place at the catalytic surface, and not in the vapour phase. R. T.

**Electrolysis of phosphate melts. II. New tungsten phosphide  $\text{W}_4\text{P}$ .** H. HARTMANN and J. ORBAN (Z. anorg. Chem., 1936, 226, 257—264; cf. A., 1931, 805).—The mixture of  $\text{PH}_3$  and  $\text{H}_2$  produced at the cathode during electrolysis of fused  $\text{NaPO}_3 + \text{LiPO}_3$  containing  $\text{WO}_3$  reacts with the latter at temp. below  $520^\circ$  and at c.d.  $> 0.0085$  and  $< 0.04$  amp. per sq. cm. to give the compound,  $\text{W}_4\text{P}$ , d 16.03. Chemical properties are described. At  $500$ — $550^\circ$   $\text{W}_4\text{P}$  decomposes irreversibly into  $\text{W}_2\text{P}$  and  $\alpha\text{-W}$ . The substance is amorphous. X-Ray examination of  $\text{W}_2\text{P}$  shows it to be hexagonal, with  $a$  6.18,  $c$  6.78 Å. F. L. U.

**Electrolytic polishing of copper, lead, tin, and their alloys, and its applications to metallography.** P. JACQUET (Bull. Soc. chim., 1936, [v], 3, 705—723).—A procedure for polishing metal and alloy specimens for micrographical examination consists in anodic treatment in a suitable acid between certain limiting c.d. The treatment of Cu surfaces in aq.  $\text{H}_3\text{PO}_4$ , and of Pb, Sn, and Pb-Sn alloys in aq.  $\text{HClO}_4$ -AcOH is described. The structures thus revealed are different from those obtained by mechanical polishing, as distortion does not occur. The mechanism of the electrolytic process is discussed. E. S. H.

**"Electrolysis" of a solid gold-copper alloy.** G. NEHLEP, W. JOST, and R. LINKE (Z. Elektrochem., 1936, 42, 150—153; cf. A., 1935, 936).—Passage of a current of 3.2 amp. for 3 months at  $1000^\circ$  through wires of a Cu-Au alloy with Au 65.7% produced an accumulation of Au at the anode. The transport no. for Cu was  $5$ — $10 \times 10^{-11}$ . F. L. U.

**Protection and decoration of aluminium and its alloys.**—See B., 1936, 278.

**Electrolysis of alkali zincate solution.**—See B., 1936, 332.

**Platinum plating.**—See B., 1936, 329.

**Chemical action of electric discharges. VIII. Production of nitric oxide by the electric arc at different frequencies.** B. SIEGRIST, C. H. WAKKER, and E. BRINER. **IX. Effect of addition of alkali and alkaline-earth metals to the electrodes on the yield of nitric oxide in industrial furnaces.** E. BRINER, C. H. WAKKER, H. PAILLARD, and G. CARRISSON. **X. Effect of increase of frequency conjoined with addition of lithium to the electrodes and enrichment of the air with oxygen on the yield of nitric oxide.** C. H. WAKKER and E. BRINER (Helv. Chim. Acta, 1936, 19, 287—308, 308—320, 320—322; cf. A., 1932, 820).—VIII. Yields of NO have been determined, using arcs

supplied with d.c., and a.c. at 50, 1410,  $10^6$ , and  $10^7$  cycles. For the same power consumption, the yield given by d.c. is  $>$  that given by a.c. at 50 or 1410 cycles, above which the yield increases with frequency. For any given type of discharge the yield increases with decreasing power consumption. The best yield, 128.5 g.  $\text{HNO}_3$  per kw.-hr., was obtained with a.c. 12 watts at  $10^7$  cycles.

IX. Using a 15-kw. Schönherr furnace, the effect of adding Li, Na, K, Be, Ca, and Ba to the Cu electrodes has been studied. The best result is obtained by the addition of 4.25% of Li, which increases the yield by 35%. The improvement is attributed to the Li facilitating ionisation and contributing to cooling of the arc. By combining the use of Cu-Li electrodes with addition of  $\text{O}_2$  to give an equimol. mixture of  $\text{N}_2$  and  $\text{O}_2$  the yield has been increased by 61%.

X. Improvement of the yield by 115% is obtained by combining Cu-Li electrodes and addition of  $\text{O}_2$  with the use of an a.c. arc at 1800 cycles. F. L. U.

**Control experiments on graphite oxidation by high-tension alternating current.** V. SIHVONEN and R. NASANEN (Suomen Kem., 1936, 9, B, 5—6).—In accordance with earlier views (A., 1933, 1019, 1020), the discharge of negative O ions at a graphite surface passes over at high voltage from passive discharge at the crystal face to an oxidative action on the edge atoms. The reaction due to the anodic component increases with increasing asymmetry of the discharge. J. S. A.

**Spectral analysis of the flame of an acetylene-air mixture in an electric field.** A. E. MALINOVSKI and V. S. ROSSICHIN (Physikal. Z. Sovietunion, 1935, 8, 541—546).—The spectra of the inner and outer cones of the stationary flame of a mixture of  $\text{C}_2\text{H}_2$  and air were examined with and without the application of an electric field (800—1300 volts per cm.). No difference in the structure or intensity of the lines in the bands due to C-C and C-H could be detected with the application of the field (direct and alternating). The continuous spectrum of both the inner and outer cones, however, decreases in intensity on application of the field. A. J. M.

**Decomposing action of X-rays on potassium iodide.** T. TOYOMA (Tōhoku J. Exp. Med., 1935, 24, 405—409).—The I-eliminating activity of the rays varies inversely with  $\lambda$ , and increases with the temp. CH. ABS. (c)

**Mercury-photosensitised decomposition of arsine.** N. L. SIMMONS and A. O. BECKMAN (J. Amer. Chem. Soc., 1936, 58, 454—459).—The rate of decomp. into As and  $\text{H}_2$   $\propto$  the intensity of radiation and is independent of  $\text{AsH}_3$  pressure at high pressures; at low pressures the rate is decreased on account of the fluorescence of activated Hg atoms. The decomp. is inhibited slightly by  $\text{H}_2$ . The quantum yield is  $1.03 \pm 0.05$  mols. of  $\text{AsH}_3$  per quantum of  $\lambda 2537 \text{ \AA}$ . The mechanism of decomp. is discussed. E. S. H.

**Law of blackening of photographic plates by ultrasonic rays.** N. MARINESCO (Compt. rend., 1936, 202, 757—759).—The blackening produced on a photographic plate by ultrasonic radiation of  $\nu = 625,000$  cycles per sec. follows the Hurter and Driffeld

law. The latter also governs the blackening of plates by ordinary light. H. J. E.

**Evolution of the latent photographic image.** C. JAUSSEAN (Ann. Physique, 1936, [xi], 5, 355—426; cf. A., 1935, 943).—An investigation of the modifications undergone spontaneously by the latent image in the time interval between exposure and development shows that the density of the developed image increases with the log of the age of the impression. The increase depends on the illumination of the plate, showing a max. for normal exposure, and on the nature and duration of action of the developer, and is attributed to a definite property of the latent image on Ag gelatinobromide. The properties of the real image and its susceptibility to chemical weakening are modified by the evolution of the latent image. It is concluded that the latent image and the developed image are not defined by the density val. of the latter. N. M. B.

**Photo-oxidation of methylene iodide.** R. A. GREGORY and D. W. G. STYLE (Trans. Faraday Soc., 1936, 32, 724—736).—The photo-oxidation of  $\text{CH}_2\text{I}_2$  in the vapour phase has been studied at  $20^\circ$ ,  $30^\circ$ ,  $35^\circ$ , and  $45^\circ$ , and at different low partial and total pressures ( $< 24$  mm.). The products are  $\text{H}_2$ , CO,  $\text{CH}_2\text{O}$ ,  $\text{HCO}_2\text{H}$ , and  $(\text{CH}_2\cdot\text{OH})_2$ . A mechanism is proposed, in which it is assumed that  $\text{CH}_2$  and the peroxidic substances  $\text{CH}_2\text{O}_2$  and  $(\text{CH}_2\text{O})_2$  are first formed, the latter two changing spontaneously into  $\text{HCO}_2\text{H}$  and  $\text{CH}_2\text{O}$  respectively. F. L. U.

**Oxidation of monochloroacetic acid by potassium permanganate at wave-lengths  $366 m\mu$  and  $436 m\mu$  with uranyl salt as photosensitiser.** J. C. GHOSH and B. B. RAY (J. Indian Chem. Soc., 1936, 13, 1—10).—The velocity of the reaction is zero-mol. with respect to  $\text{KMnO}_4$ ,  $\propto$  intensity of incident radiation, and is influenced by change in  $[\text{UO}_2\text{SO}_4]$ , whilst  $1/\text{velocity}$  plotted against  $1/[\text{CH}_2\text{Cl}\cdot\text{CO}_2\text{H}]$  gives a straight line. A reaction mechanism is suggested. E. E. A.

**Sensitised photolysis of glycollic acid and glyoxylic acid.** E. BAUR (Helv. Chim. Acta, 1936, 19, 234—246; cf. A., 1913, i, 443).—Aq.  $\text{OH}\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$  is decomposed by light in presence of fluorescein, eosin, erythrosin, chlorophyll,  $\text{FeCl}_3$ , or  $\text{UO}_2\text{SO}_4$ , giving  $\text{CH}_2\text{O}$  and  $\text{CO}_2$ , whilst  $\text{HgCl}_2$  used as a depolariser is reduced to  $\text{Hg}_2\text{Cl}_2$ .  $\text{O}_2$  plays no direct part in the photolysis, but in presence of  $\text{FeCl}_3$  it re-oxidises the  $\text{Fe}^{2+}$  produced. Under similar conditions  $\text{CHO}\cdot\text{CO}_2\text{H}$  yields only  $\text{CO}_2$ . The Na salts are changed more rapidly than the acids themselves. In all cases a stationary state is reached, in agreement with the author's theory. F. L. U.

**Decomposition of fructose in ultra-violet light.**—See this vol., 594.

**Comparative velocities of hydrolysis of certain glucosides under the influence of ultra-violet rays, acids, and enzymes.** G. TANRET (Compt. rend., 1936, 202, 881—883).—Nine glucosides have been examined. The order of velocity of hydrolysis is different for the different hydrolytic agents employed, the order for acids differing most markedly from that of the other two, for which a certain degree of similarity

may be observed. Glucosides with reducing properties are most readily hydrolysed by enzymes. M. S. B.

**Photochemical decomposition of oxalyl chloride vapour.** K. B. KRAUSKOPF and G. K. ROLLEFSON (J. Amer. Chem. Soc., 1936, 58, 443—448).— $(\text{COCl})_2$  is slowly decomposed by light of  $\lambda < 3800 \text{ \AA}$ . The reaction is unimol. and has a low quantum yield. The final products are  $\text{COCl}_2$  and  $\text{CO}$ , although  $\text{Cl}_2$  and  $\text{CO}$  are probably formed initially. It is probable that light of short  $\lambda$  breaks the mol. at the C-C linking, and that of long  $\lambda$  at the C-Cl linkings. The absorption coeffs. of  $(\text{COCl})_2$  at 3700—2400  $\text{\AA}$ . have been measured. E. S. H.

**Photolysis of lead tetramethyl and lead tetraphenyl.** P. A. LEIGHTON and R. A. MORTENSEN (J. Amer. Chem. Soc., 1936, 58, 448—454).—The pure liquid or vaporised compounds, or solutions in octane, absorb light in the ultra-violet region, decomp. thus:  $\text{PbR}_4 \rightarrow \text{Pb} + 2\text{R}_2$ . The method of radioactive indicators has been applied to determine quantum yields. The formation of Me radicals has been demonstrated. E. S. H.

**Effect of simultaneous irradiation with several wave-lengths on oxidation of mandelic acid by bromine.** J. C. GHOSH and S. K. BHATTACHARYYA (Z. physikal. Chem., 1936, B, 31, 420—430).—The photochemical oxidation in aq. solution in presence of KBr in light of  $\lambda$  366, 436, and 546 m $\mu$  is a reaction of zero order. The effect of simultaneous irradiation with two of these  $\lambda$  is  $<$  the sum of the effects produced by the two separately. In monochromatic light the velocity coeff.  $\propto$  the square root of the energy absorbed. The reaction mechanism is:  $\text{Br} + \text{AH}_2 \rightarrow \text{HBr} + \text{AH}^\cdot$ ,  $\text{AH}^\cdot + \text{Br}_2 \rightarrow \text{HBr} + \text{A}^\cdot + \text{Br}$ . Quantum efficiencies have been determined. R. C.

**Concentration of artificially produced radioelements by means of an electric field.** J. W. J. FAY and F. A. PANETH (J.C.S., 1936, 384—390; cf. A., 1935, 802).—The effects of bombardment by slow neutrons on  $\text{AsH}_3$  and org. bromides and iodides have been investigated. The active isotope  $^{33}\text{As}^{76}$  does not retain any characteristic charge which may be given to it at the moment of formation, but picks up positive and negative ions in the gas and can be deposited on electrodes of either sign. With EtI, I atoms which are activated and detached from the Et groups acquire, by exchange processes, the negative charge of I ions which are usually present in the liquid or are supplied by adding  $\text{SO}_2$  etc. The active isotope,  $^{53}\text{I}^{128}$ , is collected on Cu and Ag anodes, but not Pt, by electrolysis. Similarly, active I is collected from MeI and BuI, and active Br from EtBr, BuBr,  $\text{CH}_2\text{Br}_2$ , and  $(\text{CH}_2\text{Br})_2$ . The method is not effective in some cases, which are discussed. Practically pure radioactive isotopes are obtained in certain cases by the electric field method and concn. factors as high as 19,000 are recorded. J. G. A. G.

**Direct production of organic compounds containing artificial radio-elements.**—See this vol., 588.

**Heavy hydrogen : its importance for the study of chemical and biological problems.** W. BRANDT (Chem.-Ztg., 1936, 60, 285—288).—A review.

**Para-ortho composition of hydrogen gas produced from hydrogen atoms.** N. SASAKI and O. MABUCHI (Proc. Imp. Acad. Tokyo, 1936, 12, 39—41).—The composition of the  $\text{H}_2$  formed in the reaction  $\text{H} + \text{HI} = \text{H}_2 + \text{I}$  was investigated, the H atoms being obtained by the photochemical decomp. of HI. The product, examined by the thermal conductivity method, contained 25% *p*- $\text{H}_2$ . A. J. M.

**Deuterohydrates of krypton and xenon.** M. GODCHOT, (MLLE.) G. CAUQUIL, and R. CALAS (Compt. rend., 1936, 202, 759—760).—The unstable compounds  $\text{Kr}, 6\text{D}_2\text{O}$  and  $\text{Xe}, 6\text{D}_2\text{O}$  have been prepared and their dissociation pressures measured. They resemble the corresponding hydrates very closely. H. J. E.

**Production of large single crystals of lithium fluoride.** D. C. STOCKBARGER (Rev. Sci. Instr., 1936, [ii], 7, 133—136).—The molten salt is cooled in a Pt crucible under carefully controlled conditions. C. W. G.

**Preparation of single crystals of sodium nitrate from the molten salt.** E. V. TZECHNOVITZER (J. Phys. Chem. U.S.S.R., 1934, 5, 1452—1458).— $\text{NaNO}_3$  crystals of dimensions up to  $24 \times 20 \times 12$  mm. were prepared from  $\text{NaNO}_3$ , containing  $\text{KNO}_3$  0.03 and  $\text{Fe}_2\text{O}_3$  0.05%, by heating in a Ni crucible to  $\approx 350^\circ$ , and cooling at a uniform rate to room temp. (40 hr.) so that crystallisation started at the bottom of the crucible. CH. ABS. (e)

**Production of potassium and sodium hydroxides from the sulphates.**—See B., 1936, 273.

**Ammoniates of simple salts. I. Ammoniates of copper salts.** G. SPACU and P. VOICHESCU (Z. anorg. Chem., 1936, 226, 273—288; cf. A., 1934, 613).—Isobars of systems consisting of  $\text{NH}_3$  and the cupric salts of  $\text{H}_2\text{CrO}_4$ ,  $\text{HCNS}$ ,  $\text{HCO}_2\text{H}$ ,  $\text{AcOH}$ ,  $\text{OH}\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$ ,  $\text{NH}_2\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$ ,  $(\text{CH}_2\cdot\text{CO}_2\text{H})_2$ ,  $[\text{CH}(\text{OH})\cdot\text{CO}_2\text{H}]_2$ ,  $\text{BzOH}$ , *o*- $\text{NH}_2\cdot\text{C}_6\text{H}_4\cdot\text{CO}_2\text{H}$ , and sulphosalicylic acid have been determined between  $-80^\circ$  and  $140^\circ$ . The capacity for co-ordinating  $\text{NH}_3$  mols., and the stability of the ammoniates formed, increases with increasing strength of the acid. F. L. U.

**Dissolution of metals in potassium cyanide solution.** R. HAY (J. Roy. Tech. Coll., 1936, 3, 576—586).—Results of experiments on the dissolution of Cu, Al, Ag, Zn, Pb, and Zn-Pb in aq. KCN are discussed.  $\text{H}_2$  is evolved under certain conditions, and  $\text{O}_2$  functions as a depolariser. The composition of the deposits on partly immersed metals in air has been determined, and the cause of their formation investigated. The influence of  $\text{OH}^\cdot$  on  $[\text{H}^\cdot]$  of aq. KCN and on the rate of dissolution of Ag in KCN solution has been determined. Addition of CaO to aq. cyanide does not depend for beneficial results on the  $\text{OH}^\cdot$  radical introduced; presence of  $\text{OH}$  reduces the rate of dissolution of Ag and probably that of Au. D. C. J.

**Factors influencing reduction of alkaline copper reagents by glucose.** W. H. FORBES and A. ANDREEN-SVEDBERG (Skand. Arch. Physiol., 1934, 70, 168—185; Chem. Zentr., 1935, ii, 1067—1068).—*p*<sub>H</sub> is without effect,  $< 1\%$  of NaCl or  $\text{Na}_2\text{SO}_4$  is without

action, but  $\text{ZnSO}_4$ ,  $\text{NaHSO}_4$ , and  $\text{NaCN}$  have a disturbing influence; the influence of sugar concn. is small.

H. N. R.

**Hydration of dicalcium silicate and tricalcium silicate.** N. B. KEEVIL and T. THORVALDSON (Canad. J. Res., 1936, 14, B, 20—30).— $\beta$ - and  $\gamma$ - $\text{Ca}_2\text{SiO}_4$  silicates, exposed to saturated steam between  $110^\circ$  and  $350^\circ$ , formed three cryst. products. X-Ray diffraction patterns and optical properties showed two of these to be identical with products previously described (A., 1935, 50), whilst the third (I) had distinctive structure but variable  $\text{H}_2\text{O}$  content with limiting composition  $2\text{CaO}\cdot\text{SiO}_2\cdot\text{H}_2\text{O}$ . When conditions did not favour hydrolysis,  $\text{Ca}_3\text{Si}_2\text{O}_7$  silicate hydrated to a cryst. product (II) with probable limiting composition  $3\text{CaO}\cdot\text{SiO}_2\cdot 2\text{H}_2\text{O}$ . Hillebrandite (III), heated at  $160^\circ$ , remained unchanged, but dehydrated (III) gave a product similar to (I). (I) could be dehydrated but (II) liberated  $\text{CaO}$ . When treated with a large excess of  $\text{H}_2\text{O}$  the hydrated silicates hydrolysed to the same extent as, but more rapidly than, the anhyd. silicates.

L. A. O'N.

**Hydration of  $4\text{CaO}\cdot\text{Al}_2\text{O}_3\cdot\text{Fe}_2\text{O}_3$ .** Y. SANADA (J. Soc. Chem. Ind. Japan, 1936, 39, 46B).—The compound brownmillerite,  $4\text{CaO}\cdot\text{Al}_2\text{O}_3\cdot\text{Fe}_2\text{O}_3$ , was prepared by heating together  $\text{CaCO}_3$ ,  $\text{Al}_2\text{O}_3$ , and  $\text{Fe}_2\text{O}_3$  in the required proportions at  $1400^\circ$  for 3 hr. 0.5 g. of the finely ground product, when treated with 50 c.c. of  $\text{CO}_2$ -free  $\text{H}_2\text{O}$ , gave  $3\text{CaO}\cdot\text{Al}_2\text{O}_3\cdot\text{aq.}$  and  $\text{CaO}\cdot\text{Fe}_2\text{O}_3\cdot\text{aq.}$  Under the microscope the product was observed to form cryst. needles, hexagonal plates, and, with excess of  $\text{H}_2\text{O}$ , rhombic dodecahedra.

M. S. B.

**Formation of mercuriammonium salts from mercuriammonium nitrate by double decomposition. II. Mercuriammonium chlorate.** S. AUGUSTI (Boll. Chim. Farm., 1936, 75, 129—135).—A yellowish-white ppt. of mercuriammonium chlorate,  $\text{Hg}_2\text{NClO}_3$ , is obtained on adding aq.  $\text{KClO}_3$  to aq. ammoniacal  $\text{Hg}_2\text{NNO}_3$ . The following quant. reactions are shown to occur:  $\text{Hg}_2\text{NClO}_3 + 8\text{KI} + 4\text{H}_2\text{O} \rightarrow 2\text{K}_2\text{HgI}_4 + \text{NH}_4\text{ClO}_3 + 4\text{KOH}$  at room temp.;  $\text{Hg}_2\text{NClO}_3 + 8\text{KI} + 3\text{H}_2\text{O} \rightarrow 2\text{K}_2\text{HgI}_4 + \text{NH}_3 + \text{KClO}_3 + 3\text{KOH}$  at the b.p.;  $\text{Hg}_2\text{NClO}_3 + 2\text{Na}_2\text{S} + 3\text{H}_2\text{O} \rightarrow 2\text{HgS} + \text{NH}_3 + 3\text{NaOH} + \text{NaClO}_3$  at the b.p.;  $\text{Hg}_2\text{NClO}_3 + 4\text{Na}_2\text{S}_2\text{O}_3 + 4\text{H}_2\text{O} \rightarrow 2\text{Na}_2\text{Hg}(\text{S}_2\text{O}_3)_2 + 4\text{NaOH} + \text{NH}_4\text{ClO}_3$  at room temp.;  $\text{Hg}_2\text{NClO}_3 + 4\text{Na}_2\text{S}_2\text{O}_3 + 3\text{H}_2\text{O} \rightarrow 2\text{Na}_2\text{Hg}(\text{S}_2\text{O}_3)_2 + 3\text{NaOH} + \text{NaClO}_3 + \text{NH}_3$  at the b.p.;  $\text{Hg}_2\text{NClO}_3 + 8\text{KCN} + 4\text{H}_2\text{O} \rightarrow 2\text{K}_2\text{Hg}(\text{CN})_4 + 4\text{KOH} + \text{NH}_4\text{ClO}_3$  at room temp. Thermal decomp. produces  $\text{HgO}$ .

D. R. D.

**Potassium and sodium mercury sulphites. Potentiometric investigation. II.** G. SPACU and C. DRĂGULESCU (Z. anorg. Chem., 1936, 226, 416—424; cf. A., 1935, 1469).—Potentiometric methods indicate the existence only of the following mercuri-sulphites:  $\text{K}[\text{HgClSO}_3]$ ,  $\text{K}_2[\text{Hg}(\text{SO}_3)_2]$ , and  $\text{Na}_2[\text{Hg}(\text{SO}_3)_2]$ , no evidence of  $\text{HgSO}_3\cdot\text{NaCl}$  or of  $\text{Na}_2\text{SO}_3\cdot 2\text{HgSO}_3$  being obtained. The formation of the complex ion  $[\text{Hg}(\text{SO}_3)_2]^{2-}$  provides a method for determination of  $\text{SO}_3^{2-}$ .

J. W. S.

**Mercurous salts and their amino-compounds. I.** E. GLEDITSCH and T. F. EGDIVUS (Z. anorg. Chem., 1936, 226, 265—272, and Compt. rend., 1936, 202, 574—576).—The primary product of reaction

between aq.  $\text{NH}_3$  and  $\text{Hg}_2\text{X}_2$  ( $\text{X}=\text{Cl}$  or  $\text{NO}_3$ ) is  $\text{NH}_2\cdot\text{Hg}_2\cdot\text{X}$  (I), which decomposes reversibly into  $\text{NH}_2\cdot\text{Hg}\cdot\text{X}$  (II) and  $\text{Hg}$ . Comparison of the X-ray diagrams of (I) and (II) shows the former to be a distinct compound.

F. L. U.

**Reducing action of mercury. I. Formation of hydrogen peroxide in the interaction of mercury with hydrochloric acid in presence of oxygen.** N. H. FURMAN and W. M. MURRAY, jun. (J. Amer. Chem. Soc., 1936, 58, 429—433).—The reaction may be represented stoichiometrically as (1)  $2\text{Hg} + 2\text{HCl} + \text{O}_2 = \text{Hg}_2\text{Cl}_2 + \text{H}_2\text{O}_2$ , (2)  $2\text{Hg} + 2\text{HCl} + \text{H}_2\text{O}_2 = \text{Hg}_2\text{Cl}_2 + 2\text{H}_2\text{O}$ . The mechanism is discussed.

E. S. H.

**Halides of boron, and their m.p.** A. M. VASILIEV (Trans. Kirov Inst. Chem. Tech. Kazan, 1935, No. 4—5, 93—95).—The m.p. is  $2507^\circ$ , as calc. by Flavitski's formula (A., 1906, ii, 152) from the physical consts. of  $\text{BBr}_3$ , and  $2593^\circ$  from those of  $\text{BI}_3$ .

R. T.

**Borovanadates.** D. GHIRON (Atti R. Accad. Lincei, 1935, [vi], 22, 259—264).—The existence of two series of borovanadates has been shown, viz.,  $2\text{M}^{11}\text{O}\cdot\text{V}_2\text{O}_5\cdot 3\text{B}_2\text{O}_3$  ( $\text{M}=\text{Pb}$ ,  $\text{Cd}$ ) and  $\text{M}^{11}\text{O}\cdot\text{V}_2\text{O}_5\cdot\text{B}_2\text{O}_3$  ( $\text{M}=\text{Pb}$ ,  $\text{Cd}$ ,  $\text{Zn}$ ).

O. J. W.

**Fused "onium" salts as acids. Reactions in fused pyridinium hydrochloride.** L. F. AUDRIETH, A. LONG, and R. E. EDWARDS (J. Amer. Chem. Soc., 1936, 58, 428—429).—Al, Cd, Ca, Mg, Zn, and Cu react rapidly and Mn, Ni, Sn, Pb, and Fe slowly with fused  $\text{C}_5\text{H}_5\text{N}\cdot\text{HCl}$  (I), yielding  $\text{H}_2$  and the corresponding chlorides. Many metallic oxides dissolve in (I), forming chlorides. Solutions of metallic chlorides in (I) are electrolytically conducting; Sn, Pb, As, Sb, and Bi can be electrodeposited therefrom.

E. S. H.

**Action of dilute acids on aluminium.**—See B., 1936, 327.

**Enrichment of carbon in the heavier isotope by diffusion.** D. E. WOOLDRIDGE and F. A. JENKINS (Physical Rev., 1936, [ii], 49, 404).—Using an apparatus containing 35 separation members for the separation of gaseous isotopes by diffusion, gaseous  $\text{CH}_4$  of increased abundance in  $\text{C}^{13}$  was obtained. Spectroscopic observations showed the  $\text{C}^{12}\text{C}^{13}$  band head at  $4744 \text{ \AA.}$ , the relative intensity indicating an abundance of 6.6 at.-% of  $\text{C}^{13}$ , or an enrichment factor  $\approx 7$ . A faint head corresponding with  $\text{C}^{13}\text{C}^{13}$  was observed.

N. M. B.

**Reactions in the solid state at high temperatures. XIII. Course of reaction in formation of magnesium, strontium, and barium silicates.** W. JANDER and J. WUHRER (Z. anorg. Chem., 1936, 226, 225—247; cf. A., 1935, 944).—Mixtures of  $\text{SiO}_2$  with  $\text{MgO}$  at  $1170^\circ$ , with  $\text{SrCO}_3$  at  $920^\circ$ , and with  $\text{BaCO}_3$  at  $1010^\circ$  give rise primarily to the ortho-silicates (I), even when  $\text{SiO}_2$  is in excess, in which latter case metasilicate is formed in a subsequent reaction between  $\text{SiO}_2$  and (I). The result is in part explained by the greater readiness of (I) to crystallise, as is to be expected from the structures of the two substances.

F. L. U.

**Titanium chlorosulphonato-chloride.** G. P. LUTSCHINSKI with A. I. LICHATSHEVA (Z. anorg. Chem., 1936, 226, 338—337).—Interaction of  $\text{TiCl}_4$  (1 mol.) and  $\text{SO}_3$  (2 mols.) in  $\text{CHCl}_3$  or  $\text{SO}_2\text{Cl}_2$  solution yields the compound  $\text{Ti}(\text{SO}_3\text{Cl})_2\text{Cl}_2$  (I), a yellow cryst. substance,  $d^{20}_4$  2.012, fuming in moist air and turning white. It is insol. in  $\text{CHCl}_3$  and  $\text{SO}_2\text{Cl}_2$ . When heated it darkens and vaporises, being completely sublimed on vigorous heating, with production of  $\text{TiCl}_4$  and  $\text{SO}_3$ . Action of  $\text{SO}_3$  converts it into the compound  $\text{Ti}(\text{SO}_3\text{Cl})_3\text{Cl}$ . When  $\text{SO}_2\text{Cl}_2$  vapour is passed over heated  $\text{TiO}_2$  (I) is obtained only when the  $\text{TiCl}_4$  and  $\text{SO}_3$  produced condense together.

J. W. S.

**Allotropic modifications of lead monoxide.** E. RENCKER and M. BASSIÈRE (Compt. rend., 1936, 202, 765—767).—The  $\alpha$ -modification of  $\text{PbO}$  is transformed into  $\beta$ - $\text{PbO}$  at  $530^\circ$ . These two forms give distinct X-ray diagrams. The reverse transformation was not observed. Methods of preparing these forms are discussed. The action of conc. aq.  $\text{NaOH}$  on  $\text{Pb}(\text{OH})_2$  at  $20^\circ$  yields  $\beta$ - $\text{PbO}$ , which is transformed on keeping in contact with the solution into red  $\alpha$ - $\text{PbO}$ .  $\beta$ - $\text{PbO}$  prepared at a high temp. is also converted by conc. aq.  $\text{NaOH}$  into  $\alpha$ - $\text{PbO}$ .

H. J. E.

**Raschig's hydrazine synthesis.** M. MØLLER (Kong. dansk. Vidensk. Selsk., 1934, 12, No. 16, 59 pp.; Chem. Zentr., 1935, ii, 985—986).—With pure reagents, a 40% yield of  $\text{N}_2\text{H}_4$  can be obtained in the absence of gelatin (I).  $\text{Cu}$  in  $1.66 \times 10^{-6} M$  solution practically inhibits formation of  $\text{N}_2\text{H}_4$ .  $\text{Fe}^{\text{III}}$  to some extent, but not  $\text{Co}$ ,  $\text{Ni}$ ,  $\text{Mn}$ , or  $\text{Pb}$ , behaves like  $\text{Cu}$ . (I) or mannitol suppresses the inhibiting action. Electrolysis of  $\text{NaCl}$ - $\text{NaOH}$ - $\text{NH}_3$  (I) solutions, or use of  $\text{NaOBr}$ , affords only traces of  $\text{N}_2\text{H}_4$ .

J. S. A.

**Proof of the existence of free  $\text{NH}$  (imine) in the thermal decomposition of ammonia.** H. H. FRANCK and H. REICHARDT (Naturwiss., 1936, 24, 171).—The existence of  $\text{NH}$  in the thermal decomp. of  $\text{NH}_3$  at atm. pressure and  $2000^\circ$  is shown by the presence of the  $\text{NH}$  absorption band at  $3360 \text{ \AA}$ . The stationary  $[\text{NH}]$  is estimated at 0.1—1%. That the radical is produced by decomp. of  $\text{NH}_3$  and not by combination of  $\text{N}$  and  $\text{H}$  is shown by the fact that the band could not be obtained when  $\text{N}_2$  and  $\text{H}_2$  were heated together at  $2500^\circ$ .

A. J. M.

**Causes of spontaneous inflammation of red phosphorus prepared by the dry method.** I. I. KUKUSCHKIN and A. A. KORINFSKI (J. Chem. Ind. Russ., 1935, 12, 1240—1249).—Spontaneous inflammation takes place when the product contains > 10% of a bright red, active form of  $\text{P}$ , distinguished from ordinary red  $\text{P}$  by its smaller  $d$ , and by its ability to ppt.  $\text{Cu}$  from its solutions; contamination with white  $\text{P}$ ,  $\text{P}_2\text{O}_5$ , or  $\text{SiO}_2$  does not affect the flash point of red  $\text{P}$ . The content of active  $\text{P}$  in red  $\text{P}$  may be reduced from 11 to 2% by heating for several hr. in a steel autoclave at  $340$ — $350^\circ$ .

R. T.

**Vanadium oxychloride as a solvent.** II. F. E. BROWN and F. A. GRIFFITHS (Iowa State Coll. J. Sci., 1934, 9, 89—93; cf. A., 1931, 1405).— $\text{Cs}$ ,  $\text{Rb}$ ,  $\text{K}$ , and  $\text{Na}$  react violently with  $\text{VOCl}_3$  at  $30^\circ$ ,

$60^\circ$ ,  $100^\circ$ , and  $180^\circ$ , respectively.  $\text{Li}$  also reacts.  $\text{Ca}$  and  $\text{In}$  react slightly, and  $\text{Ga}$  forms a blue ppt.  $\text{Br}$ ,  $\text{Cl}$ ,  $\text{I}$ ,  $\text{Hg}$ ,  $\text{Se}$ ,  $\text{S}$ , and  $\text{V}$  have little reaction with  $\text{VOCl}_3$  at room temp.  $\text{S}$  reacts at high temp. The reaction of  $\text{P}$  is explosive at  $100^\circ$ .  $\text{As}$  and  $\text{Sb}$  are less vigorous and  $\text{Bi}$  is inert. Liquid  $\text{SO}_2$  and  $\text{VOCl}_3$  are immiscible. Liquid  $\text{H}_2\text{S}$  reacts, forming ppts. varying in composition between  $\text{VSCl}_3$  and  $\text{V}(\text{OH})(\text{SH})\text{Cl}$ . No stable compound was formed with  $\text{MgPhBr}$ .

CH. ABS. (e)

**Constitution of vanadium carbide.** A. MORETTE (Compt. rend., 1936, 202, 572—573; cf. A., 1935, 313).— $\text{V}_2\text{O}_5$  and excess of  $\text{C}$  heated at  $> 1800^\circ$  yield  $\text{V}_4\text{C}_3$ .

T. G. P.

**Behaviour of zinc and lead arsenites and arsenates at high temperatures.** I. M. DUBROVIN (J. Appl. Chem. Russ., 1936, 9, 40—60).— $\text{Zn}_3(\text{AsO}_3)_2$  (I) yields  $\text{ZnO}$  and  $\text{As}_2\text{O}_3$  when heated at  $400$ — $500^\circ$ ; at  $500$ — $550^\circ$  oxidation-reduction reactions take place, associated with sublimation of  $\text{As}$ , leaving a residue of  $\text{Zn}_3(\text{AsO}_4)_2$  (II) and  $\text{ZnO}$ . At  $550$ — $675^\circ$  loss of  $\text{As}$  is small, the reaction consisting chiefly of  $(\text{I}) + \text{O}_2 \rightarrow (\text{II})$ , whilst at  $> 675^\circ$  (II) dissociates as follows:  $(\text{II}) \rightarrow \text{ZnO} + \text{As}_2\text{O}_3 + \text{O}_2$ . Decomp. of  $\text{Pb}_3(\text{AsO}_3)_2$  commences at  $250^\circ$ , and is associated with oxidation by atm.  $\text{O}_2$ ; at  $700$ — $850^\circ$  the reaction consists almost exclusively of oxidation to arsenate, which undergoes thermal decomp. at  $1000^\circ$ .

R. T.

**Dehydration of sodium niobates.** P. SUE (Compt. rend., 1936, 202, 762—764).—In the dehydration of  $6\text{Nb}_2\text{O}_5 \cdot 7\text{Na}_2\text{O} \cdot 32\text{H}_2\text{O}$  intermediate di- and tetra-hydrates were formed. Dehydration commenced at  $80^\circ$ . The tetrahydrate was stable at  $110^\circ$ .  $\text{Nb}_2\text{O}_5 \cdot \text{Na}_2\text{O} \cdot 7\text{H}_2\text{O}$  was stable up to  $40^\circ$ . It yielded a monohydrate, stable to  $110^\circ$ .

H. J. E.

**Existence of perchromic acid,  $\text{H}_3\text{CrO}_8 \cdot 2\text{H}_2\text{O}$ .** R. SCHWARZ and G. ELSTNER (Ber., 1936, 69, [B], 575—579).—The product of the interaction of  $\text{CrO}_3$  and conc.  $\text{H}_2\text{O}_2$  in  $\text{Me}_2\text{O}$  is the etherate  $\text{CrO}_5 \cdot \text{Me}_2\text{O}$ , which is stable at low temp. and does not possess appreciable vapour tension, but explodes with great violence at  $> -30^\circ$ . The compound  $\text{H}_3\text{CrO}_8 \cdot 2\text{H}_2\text{O}$  (Riesenfeld *et al.*, A., 1914, ii, 279) does not exist. The reaction between  $\text{CrO}_2\text{Cl}_2$  and  $\text{H}_2\text{O}_2$  does not lead to a definite product, an equilibrium, formulated  $\text{CrO}_2\text{Cl}_2 + 2\text{H}_2\text{O}_2 \rightleftharpoons \text{CrO}_5 + 2\text{HCl} + \text{H}_2\text{O}$ , being reached.

H. W.

**Reinecke's salt,  $\text{NH}_4[\text{Cr}(\text{NH}_3)_2(\text{SCN})_4] \cdot \text{H}_2\text{O}$ .** H. D. DAKIN (Org. Syntheses, 1935, 15, 74—76).—The prep. from  $\text{NH}_4\text{SCN}$  and  $(\text{NH}_4)_2\text{Cr}_2\text{O}_7$  is described.

CH. ABS. (r)

**Reaction of tris- $\beta$ -hydroxyethylamine with tungstic acid.** F. GARELLI and A. TETTAMANZI (Gazzetta, 1935, 65, 1239—1243).—The prep. of the following compounds is described

$[\text{R}=\text{NH}(\text{CH}_2\text{CH}_2\text{OH})_3]:$

O. J. W.

**Phospho- and silico-tungstates.**—See this vol., 620.

**Hydrogen bromide (anhydrous).** J. R. RUHOFF, R. E. BURNETT, and E. E. REID (Org. Syntheses, 1935, 15, 35—38).—Prep. from  $H_2$  and Br is described.

CH. ABS. (p)

**Preparation and properties of bromine oxide  $Br_2O$ .** W. BRENSCHÉDE and H. J. SCHUMACHER (Z. anorg. Chem., 1936, 226, 370—384; cf. A., 1935, 1334).—No  $Br_2O$  could be isolated after heating Br in presence of  $HgO$ , or after passing Br vapour over heated  $HgO$ . It was obtained in concn.  $> 50\%$  of the total [Br] by action of  $HgO$  on Br in  $CCl_4$ . The reaction probably occurs thus:  $HgO + Br_2 = HgOBr_2$ ;  $HgOBr_2 + Br_2 = HgBr_2 + Br_2O$ . The absorption spectrum of the  $Br_2O$  solution in the visible region has been measured.

J. W. S.

**Exchange reactions of iodine by the method of radioactive indicators.** D. E. HULL, C. H. SHIFFLETT, and S. C. LIND (J. Amer. Chem. Soc., 1936, 58, 535).—Preliminary results, indicating exchange between I and radio-I, are reported.

E. S. H.

**Action of nascent iodine and hydriodic acid on oxides.** E. MONTIGNIE (Bull. Soc. chim., 1936, [v], 3, 704—705).—I and HI, liberated from  $CHI_3$  by photochemical decomp., can react with the oxides of alkali and alkaline-earth metals,  $Ag_2O$ ,  $HgO$ ,  $Ni(OH)_2$ , and  $Cu(OH)_2$  to form iodides.

E. S. H.

**Preparation and properties of pure iron.** J. G. THOMPSON and H. E. CLEAVES (J. Res. Nat. Bur. Stand., 1936, 16, 105—130).—A crit. review of available information.

E. S. H.

**Modern theories of corrosion. I. Water-line corrosion.** J. E. O. MAYNE (J.C.S., 1936, 366—368).—A steel plate partly immersed in de-aerated 0.01—0.1N-KCl in vac. corrodes at the water-line and  $Fe(OH)_2$  is formed. This reaction, which does not occur when the plate is completely immersed, may be due to the potential existing at the surface of the solution. Corrosion is retarded by adding EtOH, possibly owing to negative adsorption of the solute at the surface of the solvent. Similarly, water-line corrosion is caused by KBr, KI,  $KNO_3$ , and  $K_2SO_4$ , but not by  $KClO_3$ , KOH,  $K_2CrO_4$ ,  $K_2CO_3$ , and  $Na_2HPO_4$ .

J. G. A. G.

**Fundamental theories of metal corrosion. I.** ITAKA (Bull. Inst. Phys. Chem. Res. Japan, 1936, 15, 131—146).—Necessary and abs. factors to promote corrosion of the following metals are shown in parentheses: Fe ( $H_2O$ ,  $O_2$ ), Al ( $H_2O$ ,  $O_2$ ,  $Cl'$ ), Mg ( $H_2O$ ,  $Cl'$ ), Cu ( $H_2O$ ,  $Cl'$ ), Zn ( $H_2O$ ),  $\alpha$ -brass ( $H_2O$ ,  $Cl'$ ),  $\alpha + \beta$ -brass ( $H_2O$ ,  $Cl'$ ,  $O_2$ ). Equations for the mechanism of corrosion are given.

N. M. B.

**Oxides. VII. Thermal dissociation of  $\gamma$ - $Fe_2O_3$ .** A. SIMON and A. LANDGRAF (Kolloid-Z., 1936, 74, 296—300; cf. A., 1932, 468).—Tensiometric and X-ray investigations show that  $\gamma$ - $Fe_2O_3$  is unchanged by heating in vac. at  $300^\circ$ . Observations to the contrary are due to the presence of reducing agents, which cause conversion into  $Fe_3O_4$  and  $\alpha$ - $Fe_2O_3$ . Finely-divided Pt does not catalyse the decomp. of  $\gamma$ - $Fe_2O_3$  at  $300^\circ$ .

E. S. H.

**Ferric oxalate.** C. DUVAL (Compt. rend., 1936, 202, 845—846).—The absorption spectrum of aq.  $Fe^{III}$  oxalate is identical with that of K ferrioxalate and, under the influence of an electric current,  $Fe^{III}$  migrates to both anode and cathode. These results apparently confirm the formula  $Fe[Fe(C_2O_4)_3] \cdot 4H_2O$ . Since, however, there is no reaction with KSCN, the cationic Fe is apparently not free and a probable formula is  $[Fe(H_2O)_4][Fe(C_2O_4)_3]$ . An examination of the ionic migration in abs. EtOH supports this formula, since  $H_2O$  is detected at the cathode only, by the use of a very hygroscopic complex Co chloride.

M. S. B.

**Preparation of alkali ferrates. II. Basicity and chemical properties of ferrates.** A. D. DEL BOCA (An. Farm. Bioquim., 1934, 5, 120—126; Chem. Zentr., 1935, ii, 817).— $FeO_2$  is considered to be  $O \cdot Fe \cdot O$ , giving rise to salts  $M_2FeO_3$  without peroxidic properties. With acids, autoxidation occurs,  $H_2FeO_4$  and its salts being formed.  $H_2O_2$  initially yields  $H_2FeO_4$ , finally giving  $H_2O_2$ .  $HMnO_4$  yields  $Mn^{II}$ ,  $Fe^{III}$ , and  $O_2$ .

J. S. A.

**Bisdimethylglyoxime diamine cobaltic salts and their configuration.**—See this vol., 598.

**Formation and decomposition of nickel ferrites.** A. D. POGORELUI (Tsvet. Metal, 1935, No. 2, 79—96).— $NiO \cdot Fe_2O_3$  was prepared by heating NiO and  $Fe_2O_3$  at  $600$ — $1000^\circ$ . The products dissolved more slowly in aq. HCl and  $H_2SO_4$  than did NiO, and were less readily reduced by CO and  $H_2$ . Reaction with CaS proceeded equally readily in both cases. That with  $SO_2$  or  $SO_3$  at  $550^\circ$  proceeded more readily with  $NiO \cdot Fe_2O_3$  than with NiO.

CH. ABS. (e)

**Nickel ammine complexes. IV. Nickel hexammine and tetrammine compounds with water of crystallisation.** E. J. KOCIS (Magyar chem. Fol., 1934, 40, 147—150; Chem. Zentr., 1935, ii, 494).—The following compounds are described:

H. J. L.

**Ruthenium carbonyls and nitrosyls.** W. MANCHOT and W. J. MANCHOT (Z. anorg. Chem., 1936, 226, 385—415).—Action of CO at  $180^\circ/200$  atm. on Ru yields the compound  $Ru(CO)_5$  (I), m.p.  $-22^\circ$ . (I) decomposes in light or on warming, yielding orange-yellow crystals of the compound,  $Ru_2(CO)_9$  (II), which is best prepared by heating a solution of (I) in  $C_6H_6$ . (II) is stable in light and air, in org. solvents, and in conc. HCl. Decomp. begins at  $150^\circ$  in air and at  $200^\circ$  in absence of  $O_2$ . Another carbonyl, of unknown composition, is obtained as a green amorphous powder in the decomp. of (I) and by the action of dil. alkali on (II). Compounds  $RuX_2(CO)_2$  are obtained by action of halogens on (II). When heated with Ag in a current of CO these yield (I). The action of NO on (II) yields a nitrosyl compound,  $Ru(NO)_4$  or  $Ru(NO)_5$ . These compounds are compared with the corresponding Fe compounds.

J. W. S.

**Collision effects in mechanical analysis by Odén's method.** A. ROMWALTER (Mitt. berg-hüttenm. Abt. Univ. Sopron., 1934, 6, 52—57; Chem.

Zentr., 1935, ii, 886).—The method eliminates possible errors in sedimentation analysis due to collision effects.

J. S. A.

**Capillary analysis and its applications.** R. DUBRISAY (Bull. Soc. chim., 1936, [v], 3, 631–640).—The change of surface tension produced by addition of alkali or acid can be used as a means of tracing titration curves. Examples of the application of this principle to acid-alkali and similar reactions are given.

E. S. H.

**Analytical notes.** H. TRAPP (Z. anal. Chem., 1936, 104, 255–257).—(a) Approx. formulae are given for calculating the composition of gas mixtures by the displacement of one gas from a known vol. by another gas at a measured streaming rate. (b)  $\text{SnCl}_4$  is reduced by Sn to  $\text{SnCl}_2$ .

J. S. A.

**Difficulties in colorimetric determination of  $p_H$  values.** A. B. COX (Soc. Chem. Ind. Victoria, 1935, 35, 1001–1005).—Sources of error in colorimetric  $p_H$  determinations on biological solutions due to (a) reaction of  $\text{NH}_2$ -acids with certain indicators (e.g., bromocresol-purple), (b) formation of coloured lakes by Cu and other metals, (c) colour matching by light of composition differing from sunlight are discussed.

J. S. A.

**Determination of  $p_H$ .** A. VAN VIANEN (Pharm. Weekblad, 1936, 73, 350–352).—The accuracy of  $p_H$  determinations using a commercial comparator consisting of a mixed indicator and a series of comparison tubes was determined by comparing the results obtained by 17 observers for the same standard buffer solutions. An accuracy of  $\pm 0.2$ – $0.5$  was obtained.

D. R. D.

**Absolute colorimetry. XIII. Azobilirubin as an indicator.** A. THIEL and H. LOGEMANN (Biochem. Z., 1936, 284, 347–352; cf. this vol., 44).—The light extinction curves of azobilirubin (prepared from bilirubin by diazotisation in  $\text{EtOH-CHCl}_3$  and extraction with  $\text{Et}_2\text{O}$ ) are given for the  $p_H$  range of 1.54–3.10 (red–blue) (cf. A., 1934, 912; 1935, 1290). Anomalous colour changes occur in the presence of certain buffer salts.

F. O. H.

**Titration of hydrogen peroxide in presence of oxalic acid (alkali oxalates).** A. SIMON and T. REETZ (Z. anal. Chem., 1936, 104, 249–255).—Total  $\text{H}_2\text{O}_2 + \text{C}_2\text{O}_4^{2-}$  is titrated with  $\text{KMnO}_4$ , first at room temp. ( $\text{H}_2\text{O}_2$ ) and then in hot solution. To a second portion an excess of  $M\text{-Ca}(\text{NO}_3)_2$  in 10% aq.  $\text{NH}_3$  is added,  $+\text{FeCl}_3$  as catalyst, and the  $\text{H}_2\text{O}_2$  is then destroyed by boiling. The solution is finally acidified with  $\text{H}_2\text{SO}_4$ , and  $\text{C}_2\text{O}_4^{2-}$  is titrated with  $\text{KMnO}_4$ .

J. S. A.

**Mercurimetry. Titration of halogens.** M. SCHTSCHIGOL (Ann. Chim. Analyt., 1936, [iii], 18, 61–64).—The solution of  $\text{Cl}^-$  or  $\text{Br}^-$  + a mixture of 0.05N- $\text{NH}_4\text{CNS}$  and  $\text{Fe}(\text{NO}_3)_3$  is titrated with 0.1N- $\text{Hg}_2(\text{NO}_3)_2$  until colourless.  $\text{I}^-$  is treated with an excess of  $\text{Hg}_2(\text{NO}_3)_2$ , and the ppt. of  $\text{Hg}_2\text{I}_2 + \text{HgI}_2 + \text{Hg}$  is filtered off. Excess of  $\text{Hg}$  in the filtrate is oxidised with  $\text{KMnO}_4$ , and is then titrated back with  $\text{NH}_4\text{CNS}$ .

J. S. A.

(A) Determination of chlorates, bromates, and iodates by the use of liquid amalgams. (B) Ap-

plication of Wood's alloy as a reducing reagent. P. G. POPOV (Ukrain. Chem. J., 1935, 10, 413–416, 428–430).—(A)  $\text{ClO}_3^-$  is determined by adding 10 ml. of 50%  $\text{H}_2\text{SO}_4$  to 10 ml. of the solution, and shaking for 10 min. with Zn-Hg, after which  $\text{Cl}^-$  is determined by Volhard's method.  $\text{BrO}_3^-$  and  $\text{IO}_3^-$  are determined similarly, except that 7N- $\text{H}_2\text{SO}_4$  is used, and the titration is performed after 3 min.

(B) Wood's alloy may be substituted for Zn-Hg in the above procedure (at  $90^\circ$ ).

R. T.

**Sensitive reaction for chlorates, bromates, and sulphites.** I. M. KORENMAN (J. Appl. Chem. Russ., 1936, 9, 157–158).—A mixture of 1 drop of solution, 1 drop of 0.02% indigo-carmin, 1 drop of saturated aq.  $\text{Na}_2\text{SO}_3$ , and 1 drop of 3N-HCl is decolorised in presence of  $< 0.2 \times 10^{-6}$  g. of  $\text{KClO}_3$ , or  $0.24 \times 10^{-6}$  g. of  $\text{KBrO}_3$  or  $\text{K}_2\text{Cr}_2\text{O}_7$ ;  $\text{Fe}(\text{CN})_6^{3-}$  and  $\text{IO}_3^-$  do not interfere. The reaction is given by  $\text{MnO}_4^-$  and  $\text{OCl}^-$  in absence of  $\text{Na}_2\text{SO}_3$ .  $\text{SO}_3^{2-}$  ( $< 1.6$  in  $10^6$ ) can be detected by the above reaction with  $\text{KClO}_3$ , but without  $\text{Na}_2\text{SO}_3$ ;  $\text{S}^{2-}$  and  $\text{S}_2\text{O}_3^{2-}$  interfere.

R. T.

**Determination of iodine in air.** H. CAUER (Z. anal. Chem., 1936, 104, 161–169).—A measured vol. of air is washed intensively through 13% aq.  $\text{K}_2\text{CO}_3$ , using the apparatus described previously (this vol., 47). For work at low temp., saturated aq.  $\text{K}_2\text{CO}_3$  may be used. The  $\text{K}_2\text{CO}_3$  solution is evaporated down, and  $\text{K}_2\text{CO}_3$  is pptd. by addition of  $\text{EtOH}$ . The  $\text{EtOH}$  containing KI is decanted, evaporated, and the separation from  $\text{K}_2\text{CO}_3$  repeated. The residue so obtained, freed from org. matter by cautious heating, is dissolved in 0.3 c.c. of  $\text{H}_2\text{O}$ . 0.02 c.c. of  $\text{CHCl}_3$  is added, and I is liberated by addition of 0.05 c.c. of 3N- $\text{H}_2\text{SO}_4$  containing  $\text{NaNO}_2$ . The colour of the  $\text{CHCl}_3$  drop is matched against solutions of known I content. Alternatively, I may be oxidised to  $\text{IO}_3^-$  with  $\text{Cl-H}_2\text{O}$ . KI is added, and the I liberated is titrated with 0.004N- $\text{Na}_2\text{S}_2\text{O}_3$ .

J. S. A.

**Titration with 0.001N-iodine.** A. B. COX (Soc. Chem. Ind. Victoria, 1935, 35, 996–1000).—The indicator correction may be reduced by adding 0.25 ml. of 0.2N-KI per 20 ml. of solution. Titration of I with 0.001N- $\text{Na}_2\text{S}_2\text{O}_3$  is not practicable.

J. S. A.

**Standard iodine solutions.** A. H. SCOTT (J. Biol. Chem., 1936, 113, 511–513).—I solutions diluted with  $\text{H}_2\text{O}$  show an apparent loss of I; titrations should be made in 0.3M-KI.

F. A. A.

**Hydrochemical analysis. I. [Determination of hydrogen sulphide.]** W. OHLE (Angew. Chem., 1936, 49, 206–208).— $\text{H}_2\text{S}$  in  $\text{H}_2\text{O}$  is pptd. as CdS immediately after sampling by the addition of slightly acid 50% aq.  $\text{CdSO}_4$ . The ppt. is collected and treated with acidified 0.01N-I. The excess of I is titrated back with 0.02N- $\text{Na}_2\text{S}_2\text{O}_3$ .

J. S. A.

**Reversible indicator for detection of small quantities of hydrogen sulphide in the atmosphere.**—See B., 1936, 349.

**Direct titration of sulphates. Tetrahydroxybenzoquinone as internal indicator.** R. T. SHEEN and H. L. KAHLER (Ind. Eng. Chem. [Anal.], 1936, 8, 127–130).—The procedure of Schroeder (A., 1934, 46) is modified so as to extend the range of  $[\text{SO}_4^{2-}]$ .

$\text{PO}_4'''$  interferes, but when  $\geq 60$  p.p.m. are present can be eliminated by  $p_{\text{H}}$  control. EtOH may be replaced by  $\text{Pr}^{\text{e}}\text{OH}$ . The end-point may be sharpened by adding NaCl. E. S. H.

**Determination of sulphate by titration with lead nitrate, using eosin as indicator.** J. E. RICCI (Ind. Eng. Chem. [Anal.], 1936, 8, 130—132).—0.10—0.25 g. of  $\text{Na}_2\text{SO}_4$  may be determined by titration with 0.1M- $\text{Pb}(\text{NO}_3)_2$ , using 0.5% eosin as indicator, with an accuracy of about 0.0005 g. of  $\text{Na}_2\text{SO}_4$ . E. S. H.

**Determination of selenocyanides in presence of cyanides.** R. RIPAN-TILICI (Z. anal. Chem., 1936, 104, 189—192).—The potential curve shows discontinuities corresponding with formation of  $[\text{Ag}(\text{CN})_2]'$  (a); pptn. of  $\text{AgSeCN}$  (b); and pptn. of  $\text{AgCN}$  (c). Then  $\text{SeCN}' = (a) - (b)$ . J. S. A.

**Semi-micro-method of analysis for nitrogen.** A. R. RONZIO (Ind. Eng. Chem. [Anal.], 1936, 8, 122—123).—The main difficulties in the Dumas method are avoided by placing at the end of the combustion tube a heated section containing  $\text{I}_2\text{O}_5$ . A modified nitrometer is recommended. E. S. H.

**Determination of small amounts of nitric acid in sulphuric acid.**—See B., 1936, 316.

**Determination of total oxidising power, nitrite, ozone, and total chlorine in air.** II.—See B., 1936, 349.

**Colour reaction for nitric acid.** A. S. VASILIEV (J. Appl. Chem. Russ., 1936, 9, 155—156).—3 drops of 0.1%  $\beta$ -methylumbelliferone in conc.  $\text{H}_2\text{SO}_4$  are added to 2 drops of the solution, and 2 litres of  $\text{H}_2\text{O}$  are added; a lemon-yellow coloration is obtained in presence of  $0.5 \times 10^{-6}$  g. of  $\text{HNO}_3$ . R. T.

**Determination of nitrate, nitrite, and ammonia in water and effluents.**—See B., 1936, 398.

**Determination of ortho- in presence of pyrophosphate by Copaux' method.** J. COURTOIS (J. Pharm. Chim., 1936, [viii], 23, 232—238).—Conditions for accuracy have been determined (A., 1921, ii, 707).  $\text{P}_2\text{O}_7'''$  is also pptd. by  $\text{NH}_4$  Mg reagent by heating in dil. AcOH,  $\text{PO}_4'''$  being pptd. from the filtrate on adding alkali. F. O. H.

**Acidimetric determination of water-soluble and total phosphoric acid in superphosphate.**—See B., 1936, 368.

**Spectral-analytical determination of arsenic, phosphorus, and sulphur in metals, particularly platinum.**—See B., 1936, 375.

**Application of Copaux' technique to determination of arsenic acid.** J. COURTOIS (J. Pharm. Chim., 1936, [viii], 23, 269—283).—Acid solutions containing  $\text{AsO}_4'''$ , treated with  $\text{Na}_2\text{MoO}_4$  in presence of  $\text{Et}_2\text{O}$ , ppt. an oil of very indefinite composition, considered to be  $\text{AsO}_4 \cdot 12\text{MoO}_3 \cdot 24\text{—}27\text{Et}_2\text{O} \cdot 24\text{—}33\text{H}_2\text{O}$ , which may be separated and measured. The method is proposed for the determination of  $\text{AsO}_4'''$  in presence of  $\text{AsO}_3'''$ , HCl solutions giving the least unsatisfactory results. J. S. A.

**Determination of arsenic in steel.**—See B., 1936, 323.

**Ignition of silicic acid.** K. A. KRIEGER and H. S. LUKENS (Ind. Eng. Chem. [Anal.], 1936, 8, 118).— $\text{SiC}$  may be produced when  $\text{SiO}_2$  ppts. are ignited in contact with a moist filter-paper.

E. S. H.

**Determination of silica in presence of fluorine.** S. S. KOROL and V. M. KALUSHSKAJA (J. Appl. Chem. Russ., 1936, 9, 148—151).—The methods of Tischtschenko *et al.* (cf. A., 1932, 488) and of Millner *et al.* (A., 1933, 41) are equally trustworthy for determining  $\text{SiO}_2$  in presence of F compounds; that of Tananaev and Babko (B., 1930, 863, 1110) is preferred for silicofluorides. Siegel's method (A., 1929, 1158) is applicable to all cases. R. T.

**Detection and determination of carbon monoxide and dioxide in air.**—See B., 1936, 396.

**Colorimetric micro-determination of cyanides.** Application to officinal preparations, especially to mercuric cyanide. A. D. MARENZI and A. J. BANDONI (An. Farm. Biochim., 1934, 5, 135—140; Chem. Zentr., 1935, ii, 883).— $\text{CN}'$  is converted into  $\text{CNS}'$  and determined as such. H. N. R.

**Analysis of alkali metals. I. Separation of alkali metals. II. Determination of alkali metals.** T. KATÔ (J. Chem. Soc. Japan, 1935, 56, 373—397, 398—410).—I.  $\text{MeOAc}$  is recommended instead of EtOH for dissolving  $\text{Na}_2\text{PtCl}_6$  and  $\text{Li}_2\text{PtCl}_6$ .

II. The determinations of Li and Na by treating the platinichlorides with  $\text{MeOAc}$ , of Rb as  $\text{Rb}_4\text{P}_2\text{O}_7 \cdot 24\text{WO}_3$ , of Cs as  $\text{CsP}_2\text{O}_7 \cdot 24\text{WO}_3$ , and of Li as  $\text{Li}_2\text{SO}_4$  are described. CH. ABS. (e)

**Analysis of the system  $\text{NH}_2 \cdot \text{CO}_2 \cdot \text{NH}_2$ ,  $\text{NH}_2 \cdot \text{CO}_2 \cdot \text{Na}$ ,  $\text{NH}_4\text{Cl}$ ,  $\text{NaCl}$ , and adsorbed  $\text{NH}_3$ .** I. L. SCHERESCHEVSKI (J. Appl. Chem. Russ., 1936, 9, 166—170).—A scheme for the analysis of mixtures of the above substances is given. R. T.

**Drop reaction for caesium, and its adaptation to drop colorimetry.** E. S. BURKSER and M. L. KUTSCHMENT (J. Appl. Chem. Russ., 1936, 9, 145—147).—A drop of the solution is placed on a drop of conc. aq.  $\text{AuBr}_3\text{—PtBr}_4$  on filter-paper, when a black stain due to the compound  $\text{Cs}_3\text{Au}_2\text{PtBr}_{12}$  (decomp.  $175\text{—}180^\circ$ ) is formed in presence of  $\leq 0.25 \times 10^{-6}$  g. of Cs.  $\text{NH}_4$ , K, Na, and Li do not interfere, but Rb gives a similar reaction when present in considerable amount. The amount of Cs may be determined by comparing the intensity of the stain obtained with a series of standards. R. T.

**Precipitation of silver chloride. II. From silver nitrate and hydrochloric acid.** C. H. GREENE and L. D. FRIZZELL (J. Amer. Chem. Soc., 1936, 58, 516—522; cf. A., 1934, 860).—Nephelometric investigations reveal two distinct stages: an initial, rapid growth in opalescence, followed by a period of slow development to a max. and subsequent fall. The rate of development depends mainly on the concn. of the reagent in excess. Centrifugal, ultra-microscopical, and coagulation experiments support the view that there is a progressive diminution of particle size with the increasing supersaturation that results from increased concn. of pptg. reagent.

E. S. H.

**Analysis of groups I, II, and III cations in presence of phosphoric acid.** C. N. POTSCHNIK (J. Appl. Chem. Russ., 1936, 9, 140—144).—Group I metals are detected by the usual procedure, as are group II and III cations after elimination of  $\text{PO}_4^{3-}$  as  $\text{AlPO}_4$ . R. T.

**Precipitation of barium sulphate in presence of hydrochloric and nitric acids, in the cold.** L. A. VASILIEVA (Trans. Kirov Inst. Chem. Tech. Kazan, 1935, No. 4—5, 97—105).—The wt. of the ppt. obtained rises with increasing  $[\text{HNO}_3]$  to a max. when  $\text{H}_2\text{SO}_4 : \text{HNO}_3 = 1 : 60$ , and then falls to the theoretical val. when the ratio is  $1 : 150$ ; the variations obtained in presence of HCl are similar, although less marked. The phenomena are ascribed to co-pptn. of  $\text{BaCl}_2$  or  $\text{Ba}(\text{NO}_3)_2$ , together with diminishing  $[\text{Ba}^{2+}]$  and  $[\text{SO}_4^{2-}]$  due to reversal of dissociation. R. T.

**Precipitation of barium sulphate.** N. A. RUDNEV (Trans. Kirov Inst. Chem. Tech. Kazan, 1935, No. 4—5, 107—109).—The amount of precipitant pptd. together with  $\text{BaSO}_4$  when different salts of Ba are added to aq.  $\text{H}_2\text{SO}_4$  varies inversely with the solubility of the precipitant, and directly with the concn. of its anion; hence  $\text{Ba}(\text{NO}_3)_2$  is co-pptd. even in absence of  $\text{HNO}_3$ ,  $\text{BaCl}_2$  in presence of HCl, and  $\text{BaBr}_2$  only when  $\text{H}_2\text{SO}_4 : \text{HBr} = 1 : 240$ . R. T.

**Determination of magnesium metal, magnesium, and magnesium fluoride in the products of electrolytic recovery of metallic magnesium.**—See B., 1936, 329.

**Determination of zinc in sea-water using sodium diethyldithiocarbamate.** W. R. G. ATKINS (J. Marine Biol. Assoc., 1936, 20, 625).—The approx. concn. is determined by adding 10 c.c. of a 0.1% solution of the reagent to Nessler tubes containing the test sample and various concns. of Zn in neutral solution, respectively. The comparison is completed in Nessler tubes. The colour due to Cu obtained with conc. sea-water can be compared with the white standards if a Schott No. OG2 filter is used in conjunction with the latter. English Channel water contains < 8 mg. per cu.m., the limit of detection. J. W. S.

**[Detection and determination of] cadmium.** K. HELLER and F. MACHEK (Mikrochem., 1936, 19, 147—161).—A review.

**Volumetric determination of lead by Fajans' method.** S. N. ROY (J. Indian Chem. Soc., 1936, 13, 40—41).— $\text{Na}_2\text{CO}_3$  with a Na fluoresceinate indicator has been employed. E. E. A.

**Rational analysis of lead compounds in oxide and semi-sulphide lead ores.**—See B., 1936, 317.

**Polarometric titrations.** V. MAJER (Z. Elektrochem., 1936, 42, 120—123).—By measuring the current between two electrodes to which a const. p.d. is applied, one of the electrodes having a large surface of Hg at rest (and therefore unpolarisable for sufficiently small currents) and the other being a dropping Hg electrode, "polarometric" titrations involving pptn., neutralisation, or complex formation, as well as oxidation and reduction, can be carried out. The principles of the use of a dropping Hg cathode are discussed. F. L. U.

**Polarometric precipitation titrations with dropping mercury cathode.** V. MAJER (Z. Elektrochem., 1936, 42, 123—127; cf. preceding abstract).—Results of polarometric titrations of  $\text{Pb}(\text{NO}_3)_2$  with  $\text{H}_2\text{SO}_4$  and of  $\text{BaCl}_2$  with  $\text{K}_2\text{SO}_4$  (all 0.1N) are given and discussed. F. L. U.

**Determination of copper in presence of interfering elements. Modified iodometric method.** H. W. FOOTE and J. E. VANCE (Ind. Eng. Chem. [Anal.], 1936, 8, 119—121).—The modified iodometric procedure (A., 1935, 837), with controlled  $p_{\text{H}}$ , may be used to determine Cu accurately in presence of  $\text{Sb}^{\text{V}}$  or  $\text{As}^{\text{V}}$ . Addition of NaF prevents the interference of  $\text{Fe}^{\text{III}}$ . E. S. H.

**Objective colorimetric determination of copper.** C. A. GOETHALS (Z. anal. Chem., 1936, 104, 170—182).—Using a photo-electric colorimeter and filtered light, Cu may be determined colorimetrically by the following methods, at concns. down to the limit indicated. (a) As  $\text{CuSO}_4$  in acid solution; limit  $2 \times 10^{-3}$  mol. per litre. (b) As  $[\text{Cu}(\text{C}_5\text{H}_5\text{N})_4]^{2+}$  in presence of 0.5M- $\text{C}_5\text{H}_5\text{N} + 0.003\text{M-H}_2\text{SO}_4$ ; limit  $3 \times 10^{-4}$  mol. per litre. (c) As  $[\text{Cu}(\text{NH}_3)_4]^{2+}$  in presence of 10 c.c. of 28% aq.  $\text{NH}_3 + 20$  g. of  $\text{NH}_4\text{Cl}$  in 300 c.c. of solution; limit  $5 \times 10^{-4}$  mol. per litre. (d) In neutral solution in the absence of Fe, Zn, or an excess of other electrolytes, from the colour of colloidal suspensions of  $\text{Cu}_2\text{Fe}(\text{CN})_6$ ; limit  $3 \times 10^{-5}$  mol. per litre. (e) From the colour given by Cu with oxidised dimethylglyoxime (I). To the slightly acid solution,  $\text{C}_5\text{H}_5\text{N}$  is added, and then (I) +  $(\text{NH}_4)_2\text{S}_2\text{O}_8 + 5$  c.c. of 0.01M- $\text{AgNO}_3$  as catalyst. An unstable reddish violet colour is developed; limit  $2 \times 10^{-6}$  mol. of Cu per litre. (f) From the catalytic accelerating effect of  $\text{Cu}^{2+}$  on the  $\text{Fe-Na}_2\text{S}_2\text{O}_3$  reaction, in presence of  $\text{NH}_4\text{CNS}$  as indicator; limit  $2 \times 10^{-6}$  mol. per litre. By adding to an Ag solution 2 c.c. of 0.01M- $\text{CuSO}_4$ , method (e) may be applied to the determination of  $10^{-5}$  mol. of Ag per litre. J. S. A.

**Iodometric determination of copper in sugar and other liquids containing organic substances.**—See B., 1936, 388.

**Permanganate method of determining reduced copper in the determination of reducing sugars.**—See B., 1936, 388.

**Inorganic complex compounds in analytical chemistry. IV. Detection and determination of mercury.** C. MAHR (Z. anal. Chem., 1936, 104, 241—245; cf. this vol., 179).—Hg is pptd. by aq.  $\text{NH}_3[\text{Cr}(\text{CNS})_4(\text{NH}_3)_2]$  from acid (0.1N-HCl) solution as the very insol. salt  $\text{Hg}[\text{Cr}(\text{CNS})_4(\text{NH}_3)_2]_2$  (I).  $2.5 \times 10^{-6}$  g. of Hg may be so detected in presence of 20,000 parts of Cu or Pb, or 5000 parts of Cd. (I) is quantitatively pptd. from hot HCl solution, and may be dried at  $105^\circ$ , or ignited to  $\text{Cr}_2\text{O}_3$ . Alternatively, (I) may be dissolved in aq.  $\text{KCN} + \text{HCl}$ . Cr is then oxidised to  $\text{CrO}_4^{2-}$  by means of  $\text{KBrO}_3$ , and determined iodometrically. J. S. A.

**Volumetric determination of mercuric chloride.** C. CHINES (Ann. merc. Siciliana, 1934, 2, 282—286).—To 50 c.c. of boiling Fehling's  $\text{CuSO}_4$  solution are added 10 c.c. of a solution of approx. 0.5 g. of  $\text{HgCl}_2$  and 6 g. of KI in 100 c.c. of  $\text{H}_2\text{O}$ . On cooling

and keeping,  $\text{Cu}(\text{NH}_3)_4\text{HgI}_4$  is pptd. It is filtered off, and excess of I is determined in the filtrate after acidifying with  $\text{AcOH}$ . CH. ABS. (e)

**Determination of aluminium in presence of iron.** W. DAUBNER (*Angew. Chem.*, 1936, 49, 137—138).—Fe is determined by reduction of  $\text{FeCl}_3$  to  $\text{FeCl}_2$  by HI (Mohr's method); the HI is added dropwise to the heated and agitated solution, any volatilised I being trapped. Another portion of the solution is treated, in presence of  $\text{AcOH}$ , with  $(\text{NH}_4)_3\text{AsO}_4$ , and the ppt.  $[\text{AlAsO}_4 + \text{Fe}_2(\text{HAsO}_4)_3]$  is washed with 90%  $\text{EtOH}$  and dissolved in  $\text{HCl}$ . The  $\text{H}_3\text{AsO}_4$  in this solution is determined in known manner by reduction with HI; by subtracting the amount equiv. to the Fe present that equiv. to the Al is obtained, whence the Al present can be calc.

A. B. M.

**Analysis of aluminium alloys.**—See B., 1936, 327.

**Determination of gallium in aluminium.**—See B., 1936, 327.

**Detection of rhenium in the sodium carbonate bead.** H. YAGODA (*Ind. Eng. Chem. [Anal.]*, 1936, 8, 133—134).—With 0.015 mg. of Re a transitory yellow is formed in the oxidising or reducing flame. Tungstates and molybdates do not interfere.

E. S. H.

**Determination of rhenium. II. Geilmann reaction.** L. C. HURD and B. J. BABLER (*Ind. Eng. Chem. [Anal.]*, 1936, 8, 112—114; cf. A., 1932, 1224).—The conditions under which the Geilmann reaction gives quant. results have been determined.

E. S. H.

**Determination of iron in sea-water.** N. W. RAKESTRAW, H. E. MAHNCKE, and E. F. BEACH (*Ind. Eng. Chem. [Anal.]*, 1936, 8, 136—138).—Mg and Fe are co-pptd. by boiling with  $\text{NH}_4\text{HS}$ .  $\text{FeS}$  is dissolved in dil.  $\text{HCl}$ , oxidised with Br, and pptd. as  $\text{Fe}(\text{OH})_3$  by aq.  $\text{NH}_3$ . The ppt. is redissolved in  $\text{HCl}$ , oxidised, and Fe is determined colorimetrically by KCNS. The colour is stabilised by the addition of  $\text{OH} \cdot [\text{CH}_2]_2 \cdot \text{OBu}$ .

E. S. H.

**Brucine sulphate as internal indicator in titrations with standard dichromate solution.** D. S. NARAYANAMURTHI and T. R. SESHADRI (*Proc. Indian Acad. Sci.*, 1936, 3, A, 38—42; cf. A., 1933, 800).—With a 1% solution of brucine in  $3N\text{-H}_2\text{SO}_4$  as indicator, and total acidity  $\leq 2N$ , the colour change (green to red) is more distinct than that of  $\text{NHPh}_2$ , and its distinctness is unaffected by  $\text{Fe}^{++}$  (in large excess),  $\text{Hg}^{++}$ ,  $\text{Hg}_2^{++}$ , or  $\text{Sn}^{++++}$ . It can also be used in titration of  $\text{Fe}^{++}$  with  $\text{KMnO}_4$  in presence of  $\text{HCl}$ .

L. J. J.

**Diphenylcarbazide.** An internal indicator for use in the titration of iron with dichromate. H. E. CROSSLEY (*Analyst*, 1936, 61, 164—169).—A standardised method is described. The end-point, from violet to colourless, is very sharp and the titration is not affected by the previous use of  $\text{SnCl}_2$  and  $\text{HgCl}_2$  or Zn for reduction. A correction is necessary for the amount of indicator oxidised, but the method is of general application and gives accurate results.

E. H. S.

**Determination of iron by titanium titration and by 2:2'-dipyridyl colorimetry.** W. D. MCFARLANE (*Ind. Eng. Chem. [Anal.]*, 1936, 8, 124—126).—A horizontal micro-burette for titration with dil.  $\text{TiCl}_3$  solutions is described. Modified colorimetric procedure is recommended.

E. S. H.

**Spectral determination of chromium [alloyed with aluminium].**—See B., 1936, 375.

**Tests for molybdenum, lead, and cobalt in minerals and rocks.** H. LEITMEIER and F. FEIGL (*Tsch. Min. Petr. Mitt.*, 1936, 47, 313—327).—The following are delicate colour reactions for detecting the presence of minute quantities. Ca xanthate gives a reddish-violet colour with Mo. In  $\text{AcOH}$  solution benzidine gives a deep blue with  $\text{PbO}$  (in the absence of Mn). Alkali thiocyanates form double salts with Co (even in presence of much Fe and Ni) which are sol. in a mixture of  $\text{Et}_2\text{O}$  and  $\text{EtOH}$  giving a blue colour.

L. J. S.

**New indicators for direct titration of tungstate with lead nitrate.** Z. RAICHINSTEIN and N. KOROBV (*Z. anal. Chem.*, 1936, 104, 192—198; cf. A., 1935, 951).—Diamine-scarlet and diamineazo-scarlet may be used as adsorption indicators. The presence of  $\text{NH}_4\text{NO}_3$  interferes.

J. S. A.

**Separation of stannic oxide from various oxides by ignition with ammonium iodide. Application to analytical purification of ignited stannic oxide.** E. R. CALEY and M. G. BURFORD (*Ind. Eng. Chem. [Anal.]*, 1936, 8, 114—118).— $\text{SnO}_2$  is quantitatively volatilised as  $\text{SnI}_4$  when heated at 400—500° with excess of  $\text{NH}_4\text{I}$ . Separation from most other oxides may thus be effected. In the determination of Sn in alloys as  $\text{SnO}_2$ , the method may be used advantageously for purification of  $\text{SnO}_2$ .

E. S. H.

**Precipitation of tin and antimony salts by organic bases in presence of potassium iodide: application to analytical characterisation of these metals.** J. A. GAUTIER (*J. Pharm. Chim.*, 1936, [viii], 23, 283—290).—Antipyrine (I) gives with solutions of Sb in presence of KI a yellow-orange ppt.; Sn similarly gives a less sensitive white ppt. The reaction is applied to the solution, containing Sb but little Sn, obtained by digesting the Sb, Sn, and As sulphides with  $\text{HCl}$  at 80°. Other org. bases give reactions similar to, but less sensitive than, that of (I).

J. S. A.

**Determination of tin in minerals and metallurgical residues by 0.1N-potassium bromate.**—See B., 1936, 278.

**Colour reaction of titanium with ascorbic acid and other molecules containing the group  $\cdot\text{C}(\text{OH})\cdot\text{C}(\text{OH})\cdot$ .** J. ETTORI (*Compt. rend.*, 1936, 202, 852—854).—When a very dil. solution of  $\text{Ti}(\text{SO}_4)_2$  is added to ascorbic acid no coloration is observed at  $p_H < 3$ . At  $p_H 3$  there is a light yellow coloration which gradually changes until it becomes an intense reddish-brown at  $p_H 4.6$ . This diminishes with diminishing acidity and disappears at  $p_H 5.2$ . In alkaline solution the colour is pale rose. With too large a proportion of  $\text{Ti}(\text{SO}_4)_2$  pptn. of  $\text{Ti}(\text{OH})_4$  may take place with decolorisation of the solution.

All other compounds found to give the same type of reaction, *e.g.*, dihydroxymaleic acid, pyrocatechol, gallic acid, etc., contain the group  $\cdot\text{C}(\text{OH})\cdot\text{C}(\text{OH})$ .

M. S. B.

**Determination of gold with avoidance of the cupellation process.** J. DONAU (Z. anal. Chem., 1936, 104, 257—270).—A method described previously (cf. A., 1935, 1096) is improved. A Cd (87%)—Zn alloy is used for inquartation, permitting the use of glass ignition tubes. In presence of Pd repeated treatment of the inquartation mass with  $\text{HNO}_3$  is necessary: with >20% of Pd repeated inquartation may be required. In the presence of Sn, the Au+ $\text{SnO}_2$  resulting from the  $\text{HNO}_3$  treatment of the inquartation mass is heated with an excess of  $\text{NH}_4\text{Cl}$ , whereby Sn is quantitatively removed as  $\text{SnCl}_4$ .

J. S. A.

**Apparatus for extraction on a very small scale.** K. SCHMALFUSS (Chem. Fabr., 1936, 9, 161—162).—A modified Soxhlet apparatus has the advantage of using only small amounts of substance and of solvent (*e.g.*, 0.5 g. and 40 c.c., respectively). Fewer extractions, of only 1.5 hr., are necessary.

D. R. H.

**Calibration of platinum thermometers at the b.p. of sulphur.** C. D. NIVEN (Canad. J. Res., 1936, 14, A, 1—15).—Experimental technique, errors, and calculation are discussed. The accuracy of determination of  $\delta$  is considered to be limited to the third decimal place.

L. A. O'N.

**Recent revisions of high temperatures.** H. T. WENSEL (J. Amer. Ceram. Soc., 1936, 19, 81—86).—The correct method of converting temp. vals. based on Wien's law to those based on the International Scale is described. In giving corrections to be applied to quoted temp. such corrections must have been calc. from the consts. used in the original temp. scale. The implication that a recent correction table (B., 1936, 21) can be universally used is erroneous.

J. A. S.

**Determination of surface temperatures.** T. YOSHII (J. Japan. Ceram. Assoc., 1935, 43, 352—357).—Methods depending on fusion, ignition, or colour changes of suitable substances applied to the surface are proposed.

CH. ABS. (e)

**Low-temperature thermostat.** G. B. HEISIG (Ind. Eng. Chem. [Anal.], 1936, 8, 149).—A const. temp. between 25° and -75° can be maintained by means of solid  $\text{CO}_2$ , using the apparatus described. The bath contains  $\text{COMe}_2$ , EtOH, or kerosene, according to the temp. required.

E. S. H.

**Electrically heated thermostat.** G. VAN DE VOORDE (Natuurwetensch. Tijds., 1936, 18, 21—22).

D. R. D.

**Photo-electric photometer.** L. E. HOWLETT (Canad. J. Res., 1936, 14, A, 38—42).—Apparatus for measuring light transmitted by glasses and solutions is described. It has been used for the determination of the amounts of dyes removed from solution by adsorbents, and the concn. and purity of substances in solution.

A. J. M.

**Photometry of different coloured light sources.** M. PIRANI and R. ROMPE (Naturwiss., 1936, 24, 142).

—It is suggested that a phosphor or fluorescent liquid should be used as a frequency transformer for light, thus enabling the intensities of different coloured lights to be compared by comparison of the intensity of phosphorescence or fluorescence. The process is especially simple if a fluorescent liquid is used in such concn. that the incident light is completely absorbed by a thin layer of the liquid, since in this case a knowledge of the absorption curve of the liquid is not necessary, and the intensity of the fluorescence  $\propto$  the no. of incident light quanta. The method gave the val. 250:1 for the intensity ratio of the Hg lines (5770+5791 Å.) and 4916 Å. The errors of the method are discussed. Suitable fluorescent liquids for ultra-violet light are an EtOH solution of resculin, and an EtOH solution of Et dihydrocollidinedicarboxylate.

A. J. M.

**Photomagnetron and its applications in measuring low light intensities.** A. DAUVILLIER (Compt. rend., 1936, 202, 738—740).—A photo-electric method, with a photo-electric device for varying the light flux, is described.

H. J. E.

**Microscopical determination of indices of refraction of resinous substances and minerals of high refringence.** N. VEDENEJEVA, S. GRUM-GRSHMAILLO, and A. VOLKOV (Compt. rend. Acad. Sci. U.R.S.S., 1935, 4, 207—210).—An interferometric method, in which a plano-convex lens is utilised, is described. The dispersions of 16 samples of piperine containing 24—84% of LiI, NaI, etc. have been determined.

R. S.

**Rotating sector for quantitative analytical spectrography.** M. F. HASLER and R. W. LINDHURST (Rev. Sci. Instr., 1936, [ii], 7, 137—139).—A half-cylindrical shutter is mounted in front of the film.

C. W. G.

**Recent results and methods of vacuum spectroscopy.** H. BOMKE (Physikal. Z., 1936, 37, 222—260).—A review.

**Arrangement for converting a spectrograph into a monochromator.** A. CHEVALLIER and P. DUBOULOZ (Bull. Soc. Chim. biol., 1936, 18, 428—430).

A. L.

**Standard source of ultra-violet radiation for calibrating photo-electric dosage intensity meters.** W. W. COBLENTZ and R. STAIR (J. Res. Nat. Bur. Stand., 1936, 16, 83—92).—The quartz Hg-arc lamp is well adapted for the purpose by reason of the high intensity and favourable distribution of the ultra-violet emission lines at 2967—3132 Å. Methods of calibration of ultra-violet output in abs. units are described.

E. S. H.

**Refractometer and other refractive index methods.** B. W. ANDERSON (Gemmologist, London, 1934, 3, 216—222).— $\text{C}_2\text{I}_4$  and S dissolved in  $\text{C}_2\text{H}_2\text{I}_2$  give a stable liquid of  $n_D$  1.81.  $\text{AsPhI}_2$  has  $n_D$  1.843.  $\text{Se}_2\text{Br}_2$  has  $n_{D,1}$  1.96. The use of a hemisphere of Zn blende ( $n_D$  2.37) is suggested for measuring liquids.

CH. ABS. (e)

**Colorimetric analysis by the photo-electric cell.** N. STRAFFORD (Analyst, 1936, 61, 170—177).—A photo-electric colorimeter for the measurement of relative colour intensities by use of absorption density

determinations is described. Measurements are independent of the human eye, and the calibration curve, which is virtually a straight line, is always available. Notes on the choice of working conditions and on the applications are given. E. H. S.

**X-Ray powder camera.** M. J. BUERGER (Amer. Min., 1936, 21, 11—17). L. S. T.

**Precision lattice constants from X-ray powder photographs.** M. U. COHEN (Rev. Sci. Instr., 1936, [ii], 7, 155).—Corrections (cf. A., 1935, 598). C. W. G.

**General-utility vacuum chamber for X-ray fine structure photographs.** E. FRANKE (Z. physikal. Chem., 1936, B, 31, 454—458).—A convenient high-precision apparatus is described. R. C.

**Measurement of the angle between the optical axes and determination of the optical sign (of crystals) by means of the refractometer.** H. BUTTGENBACH (Bull. Acad. roy. Belg., 1936, [v], 22, 125—133). A. J. M.

**Guarded-field X-ray ionisation chamber.** L. S. TAYLOR and G. SINGER (J. Res. Nat. Bur. Stand., 1936, 16, 165—169).—Modified apparatus is described (cf. A., 1930, 1502). E. S. H.

**Electrophysical methods in analytical chemistry.** J. KRÖNERT (Chem. Fabr., 1936, 9, 133—138).—The applications of  $p_H$ , conductivity, electro-optical, and magnetic measurements to technical problems are reviewed. J. S. A.

**Ionisation gauge for atomic beam measurements.** R. D. HUNTOON and A. ELLETT (Physical Rev., 1936, [ii], 49, 381—387).—Various factors influencing the design of a gauge are discussed, and an arrangement to fulfil the necessary requirements is described. Beam pressure changes as low as  $3 \times 10^{11}$  mm. Hg, or approx.  $3 \times 10^9$  Hg atoms per sq. cm. per sec., can be measured. N. M. B.

**Single sparks and interrupted alternating-current arcs and their application to quantitative spectroscopic analysis.** T. KOSBAHN (Ann. Physik, 1936, [v], 25, 625—644).—The optical and electrical conditions necessary for obtaining light sources of max. reproducibility have been investigated. Electrically and spectroscopically reproducible single sparks can be produced in non-inductive circuits. An arrangement for producing intense interrupted a.c. arcs, and the effect of discharge conditions on their spectral character, are described. L. J. J.

**Apparatus for the conductometric determination of carbon monoxide and dioxide (and benzene vapour) in air.**—See B., 1936, 349.

**Differential electrometric titration apparatus.** S. SAITO (Bull. Inst. Phys. Chem. Res. Japan, 1936, 15, 109—123).—A differential electrode and galvanometer are used, and polarisation is reduced. Al may be determined volumetrically, using  $H_2C_2O_4$ , with a sharp end-point. The addition of a little  $H_2SO_4$  increases the sharpness of the end-point in the titration of  $Cl'$  and  $Br'$ , and 0.1 mg. of  $Br'$  in presence of 6 mg. of  $Cl'$  is titratable. R. S. B.

**Glass electrode with galvanometer reading.** L. MICHAELIS (Science, 1936, 83, 213—214). L. S. T.

**Glass electrode for measurement of  $p_H$  of unbuffered solutions in simple compensation circuit.** K. SCHWABE (Z. Elektrochem., 1936, 42, 147—150; cf. A., 1935, 1341).—A spherical glass electrode permanently housed in an outer tube, with provision for a continuous renewal of the liquid in which it is immersed, is suitable for measuring the  $p_H$  of unbuffered solutions, using the ordinary compensation method. A full description is given. F. L. U.

**Permanent glass electrode for measurement of  $p_H$  values.** G. PARSY (J. Soc. Leather Trades Chem., 1936, 20, 188—195).—In a new form of glass electrode a piece of Pt foil is suspended in aq.  $PtCl_4$  in a Haber glass bulb, mounted in a glass vessel filled with the solution under test. The apparatus is always ready for immediate use and results are quickly obtained. D. W.

**Potentiometric volumetric analysis with three electrode pairs connected in series.** L. SZEBELÉDY and J. JÓNÁS (Z. anal. Chem., 1936, 104, 271—278).—The titration vessel has three pairs of electrodes recessed in its side, which are brought into action without short-circuiting each other when the vessel is tilted. A threefold increase in sensitivity is thus obtained. J. S. A.

**Thermionic titrimeter without batteries.** H. H. WILLARD and O. B. HAGER, jun. (Ind. Eng. Chem. [Anal.], 1936, 8, 144—145).—An a.c. voltmeter for potentiometric titrations is described. E. S. H.

**Electrostatic dust count sampler.** E. C. BARNES and G. W. PENNEY (J. Ind. Hyg., 1936, 18, 167—172).—Of the three methods of collecting dust particles from samples of air, centrifugal, thermal, and electrostatic pptn., the last has definite advantages. An apparatus for carrying it out is described. W. O. K.

**Continuous-reading electron-tube conductance meter.** R. L. GARMAN (Ind. Eng. Chem. [Anal.], 1936, 8, 146—147).—The apparatus combines an audio oscillator bridge and a detector meter system. Its application to conductometric titration is described. E. S. H.

**Investigation of piezo-electric substances in powder form.** J. ENGL and I. LEVENTER (Naturwiss., 1936, 24, 217—218).—The powder is suspended in a liquid of no dielectric loss (e.g.,  $C_6H_6$ ) in a high-frequency field (400 volts per cm.), the mixture being placed in a condenser vessel for determination of dielectric loss. The measured expansion is supposed  $\propto$  temp. change, and the loss (product of temp. change and  $\lambda$ ) plotted against  $\lambda$ . For quartz powder there is a resonance at 103 m., agreeing with the val. for quartz plates. The max. heating at resonance  $\propto$  (field strength)<sup>2</sup>. A. J. M.

**Visual conductometry.** II. L. WOLF (Chem. Fabr., 1936, 9, 139—140; cf. this vol., 305).—An improved a.c. circuit for conductometric titrations is given. J. S. A.

**Apparatus for direct determination of radon in water and in air.** F. BEHOUNEK (Physikal. Z., 1936, 37, 203—208).—The first apparatus will measure the radioactivity of  $H_2O$  to 2 Mache units. The second is portable, and is adapted for the determination of the activity of air. In both methods the strength of the activity is read directly on a scale.

A. J. M.

**Modified Nessler tube set.** G. W. CORNELL (Soc. Chem. Ind. Victoria, 1935, 35, 1008—1010).

J. S. A.

**Burette for alkali titrations.** L. S. KEYSER (Ind. Eng. Chem. [Anal.], 1936, 8, 121).

E. S. H.

**Burette for potentiometric titrations.** L. S. KEYSER (Ind. Eng. Chem. [Anal.], 1936, 8, 82).

E. S. H.

**Emulsifier.** R. AUERBACH (Kolloid-Z., 1936, 74, 285—287).—Apparatus and technique are described.

E. S. H.

**Accuracy attainable with the Chattock tilting manometer.** W. F. COPE and R. HOUGHTON (J. Sci. Instr., 1936, 13, 83—88).—An accuracy of 0.1% can be obtained by the application of corrections.

C. W. G.

**Micromanometer.** H. W. SMITH (Rev. Sci. Instr., 1936, [ii], 7, 157—158).—Liquid in an inclined tube is brought to a predetermined mark by means of a micrometer screw.

C. W. G.

**Measurement of the coefficients of absorption of ultrasonic waves in gases.** L. BELAVSKAJA (Bull. Acad. Sci. U.R.S.S., 1935, 917—925).—The piezo-electric properties of quartz are utilised.

C. W. G.

**Bacteria-proof filter.** F. WOKES (Pharm. J., 1936, 136, 313).—Pressure generated by a cycle pump forces the liquid through a Seitz filter.

C. W. G.

**Laboratory sublimation apparatus.** S. T. BOWDEN (J. Sci. Instr., 1936, 13, 97—98).—Sublimation may be carried out in vac. or in a current of inert gas.

C. W. G.

**Surface-tension measurements of viscous liquids.** A. H. PFUND and E. W. GREENFIELD (Ind. Eng. Chem. [Anal.], 1936, 8, 81—82).—The depth of the small depression, produced when an air jet impinges on the surface of a viscous liquid, is an inverse function of the surface tension of the liquid. Apparatus and technique for application of the method are described.

E. S. H.

**Application of viscosimetry and plastometry to problems of applied mineralogy.** M. P. VOLAROVITSCH (Trans. Inst. Econ. Min. U.S.S.R., 1934, No. 66, 56 pp.).—A high-temp. viscosimeter consisting of two coaxial Pt-Ir cylinders, the outer of which rotates, is described. Measurements with various

slags, glasses, and minerals are described and discussed.

CH. ABS. (e)

**Extraction apparatus.** F. C. OPPEN (Ind. Eng. Chem. [Anal.], 1936, 8, 110—111).—A modified Soxhlet-type apparatus is described.

E. S. H.

**[Efficiency of] desiccators.** H. S. BOOTH and L. MCINTYRE (Ind. Eng. Chem. [Anal.], 1936, 8, 148—149).—A considerable time must elapse before the air inside a desiccator is reasonably dry, after the cover has been removed momentarily.  $BaO$  is a useful desiccant.

E. S. H.

**Laboratory desiccants: silica gel.** F. G. LENOX (Soc. Chem. Ind. Victoria, 1935, 35, 988—996).—The use of  $SiO_2$  gel as a laboratory desiccant is described.

J. S. A.

**Apparatus for isolation of fluorine.** Willard and Winter method. W. K. GILKEY, H. L. ROHS, and H. V. HANSEN (Ind. Eng. Chem. [Anal.], 1936, 8, 150—151).—Modified distillation procedure is recommended (cf. A., 1933, 242).

E. S. H.

**Device for determining rate of siphoning in metal extraction systems.** R. S. ASBURY (Ind. Eng. Chem. [Anal.], 1936, 8, 152).—An electrical device for registering siphoning in a steel Soxhlet apparatus is described.

E. S. H.

**Rapid mixer.** D. H. NELSON (Ind. Eng. Chem. [Anal.], 1936, 8, 111).—A spiral bit is recommended for preparing analysis samples of emulsions and plastics.

E. S. H.

**Control of high lights in reading microbalance swings.** P. H. M. P. BRINTON (Ind. Eng. Chem. [Anal.], 1936, 8, 104).—Observation is facilitated by using a dark cardboard screen, provided with a circular hole, in front of the lens.

E. S. H.

**Control of pressure during vacuum distillation.** G. GOETHALS (Natuurwetensch. Tijds., 1936, 18, 18—20).— $P$  may be maintained const. within  $\pm 0.04$  mm. by means of Jacobs' apparatus (A., 1935, 321).

D. R. D.

**Formation of metallic blacks on thin foils by evaporation.** R. V. JONES and B. V. ROLLIN (J. Sci. Instr., 1936, 13, 130—131).—In  $H_2$  or He at 0.1—3 mm. there is no difficulty in condensing metals evaporated from hot filaments.

C. W. G.

**Ozoniser.** R. P. JACQUEMAIN and G. BALLOUÉ (Bull. Soc. chim., 1936, [v], 3, 701—704).—The simple apparatus described gives a higher yield of  $O_3$  than is obtained with the Berthelot ozoniser.

E. S. H.

**Guide for crystal drawing.** W. M. McNABB and J. W. McNABB (J. Franklin Inst., 1936, 221, 539—546).—Directions for drawing crystals from gnomonic projections are given.

C. W. G.

## Geochemistry.

**Ozone measurements and the possible connexion of ozone with the sunspot cycle.** F. E. FOWLE (Trans. Amer. Geophys. Union, 1934, 160—162; cf. A., 1935, 59).—New data show an even higher mean val. of  $O_3$ , despite the min. for sunspots.

CH. ABS. (e)

**Determination of the ozone content of the air layer near the ground by a photo-electric counter.** R. STOLL (Helv. phys. Acta, 1935, 8, 3—38; Chem. Zentr., 1935, ii, 343).—Measurements were made with a photo-electric counter at distances of 405—1555 m. from a Hg arc. The atm. [ $O_3$ ] was

deduced from light intensity measurements in the region 2600—3100 Å. An average  $O_3$  layer of  $27 \times 10^{-4}$  cm. per km. (Arosa) and  $10 \times 10^{-4}$  cm. per km. (Zurich) was found. H. J. E.

**Isotopes in snow and rain water.** W. A. ALEXANDER and L. A. MUNRO (Canad. J. Res., 1936, 14, B, 47).—April snow  $H_2O$ , investigated by the balanced float method, showed a decrease in  $d$  of  $3.9 \times 10^{-6}$  g. per c.c. Appreciable fractionation of  $H_2O$  into its isotopic forms occurs in April. L. A. O'N.

**Radioactivity of spring water.** Y. DEUX (Petit J. Brasseur, 1935, 43, 507, 510; Chem. Zentr., 1935, ii, 734).—The determination of the radioactivity of natural  $H_2O$  is described. J. S. A.

**Radioactivity of mineral springs of the group Cachat d'Evian.** R. CASTAGNÉ and (MILLÉ.) D. OSBORNE (Compt. rend., 1936, 202, 567—569).—Data are recorded. T. G. P.

**Oceanographic research at the Scripps Institute of Oceanography.** T. W. VAUGHAN (Trans. Amer. Geophys. Union, 1934, 222—225).—Salinity data for the region between the Californian coast and the Philippines are recorded and discussed. CH. ABS. (e)

**Temperature-salinity correlation with the Florida Current.** C. O'D. ISELIN (Trans. Amer. Geophys. Union, 1934, 208—209). CH. ABS. (e)

**German calcium chloride springs.** H. HARRASSOWITZ (Kali, 1935, 29, 75—80; Chem. Zentr., 1935, ii, 820).—Analyses are given of German mineral springs of secondary origin with  $Ca : Cl = 1 : 2$ . J. S. A.

**Morven meteorite, New Zealand.** C. O. HUTTON (Min. Mag., 1936, 24, 265—275).—This stone, weighing 7100 g., was found in 1925 near Morven in South Canterbury. The microscopical characters are described and detailed chemical analyses were made of the magnetic and non-magnetic portions sol. and insol. in aqua regia. The mineral (modal) composition is olivine 40.74, bronzite 20.93, diopside 3.68, feldspars 10.34, metallic Ni-Fe 13.19, troilite 5.67% etc.  $Fe + Co : Ni$  in the metal 9.58;  $MgO : FeO$  in silicates 2.45. The stone is classed as a veined and brecciated grey bronzite-olivine-chondrite. This is the fourth meteorite to be recorded from New Zealand. L. J. S.

**The Bruno meteorite.** H. H. NININGER (Amer. J. Sci., 1936, [v], 31, 208—222).—Analyses are given. C. W. G.

**Diabase-porphyrite and glaucophane rocks in the North Calabrian trias.** H. W. QUITZOW (Nachr. Ges. Wiss. Göttingen, 1935, [iv], 1, 83—118; Chem. Zentr., 1935, ii, 342). H. J. E.

**Maxixe beryl. II. Analysis and separation of beryllium and aluminium and alkalis.** W. ROEBLING and H. W. TROMNAU (Zentr. Min., A, 1935, 134—139; Chem. Zentr., 1935, ii, 495; cf. this vol., 49).—Analysis gave  $SiO_2$  62.52,  $Al_2O_3$  18.08,  $Fe_2O_3$  0.03,  $BeO$  11.30,  $CaO$  0.22,  $MgO$  0.25,  $CuO$  trace,  $Li_2O$  0.98,  $Na_2O$  1.28,  $Cs_2O$  2.80,  $B_2O_3$  0.39, and loss on ignition 2.20%. Al and Be were separated by the hydroxyquinoline or guanidine

carbonate methods, after repeated pptn. with aq.  $NH_3$  to remove alkalis. H. J. E.

**Alteration of the rocks of the Eibenstock-Neudek [Saxony-Bohemia] granite massif.** E. O. TEUSCHER (Tsch. Min. Petr. Mitt., 1936, 47, 273—312).—Later pneumatolytic and hydrothermal processes have given rise to greisenisation, kaolinisation, silicification, chloritisation, etc. in the various granitic rocks, with the production also of tourmaline, topaz, and deposits of Sn ore. L. J. S.

**Lead-uranium ratio of siliceous pitchblende from Great Bear Lake, N.W.T., Canada, and its possible age.** J. P. MARBLE (J. Amer. Chem. Soc., 1936, 58, 434—437).—A sample yields a "corr." Pb ratio of 0.193, corresponding with an age of  $1323 \times 10^6$  years. E. S. H.

**Hydrothermal synthetic investigations on  $Al_2O_3$ - $SiO_2$ - $H_2O$  system.** W. NOLL (Fortschr. Min., 1935, 19, 46—47; Chem. Zentr., 1935, ii, 819).—Under the conditions of hydrothermal epimagmatic and metamorphic mineral formation, up to  $400^\circ$  with  $SiO_2 : Al_2O_3 > 2 : 1$ , kaolin is formed, and at  $400$ — $500^\circ$  a pyrophyllite mineral. With excess of  $Al_2O_3$ , böhmite is formed up to  $400^\circ$ ; corundum is formed at  $500^\circ$  from pure  $Al_2O_3$ . J. S. A.

**Stability of an argillite inclusion in basalt.** H. VON WARTENBERG (Nachr. Ges. Wiss. Göttingen, 1935, [iv], 1, 119—121; Chem. Zentr., 1935, ii, 342).—The inclusion was fused only on the outside. The basalt was probably near its m.p. when the inclusion was formed. H. J. E.

**Alkaline trachite from Dschebel Auenât in the Lybian desert.** P. GALLITELLI (R. Ist. lomb. Sci. Lett., 1934, [ii], 67, 731—736; Chem. Zentr., 1935, ii, 342).—The chief constituent was sanidine, together with pyroxene, agirine, nepheline, and sodalite. H. J. E.

**Geological-petrographical investigation of potash deposits in the Werra region.** F. BESSERT (Kali, 1935, 29, 27—30, 40—43, 53—58, 63—66, 73—75; Chem. Zentr., 1935, ii, 343). H. J. E.

**Crystallisation of hornblende and mica from artificial silicate melts.** D. P. GRIGORIEV (Zentr. Min., 1935, A, 117—123; Chem. Zentr., 1935, ii, 341—342).—Hornblende was synthesised from a melt containing (in parts by wt.):  $K_2O$  1,  $Al_2O_3$  0.4—0.5,  $MgO$  6,  $SiO_2$  6,  $CaF_2$  1. Optical data are given. H. J. E.

**Mineralogy of asbestos. Ishkyldite, a new structural variety of chrysotile.** F. V. SIROMIATNIKOV (Amer. Min., 1936, 21, 48—54).—*Ishkyldite* (I),  $H_2Mg_{15}Si_{11}O_{47}$ ,  $d$  2.62,  $n_g$  1.573,  $n_p$  1.566, from Ishkyldino, Middle Volga District, has  $SiO_2$  42.49,  $Al_2O_3$  1.27,  $Fe_2O_3$  2.01,  $FeO$  2.73,  $MgO$  38.28,  $CaO$  none,  $Na_2O + K_2O$  0.02,  $H_2O$ —0.79,  $H_2O +$  11.88,  $CO_2$  0.35,  $TiO_2$  trace,  $MnO$  0.06,  $Cr_2O_3$  trace,  $NiO$  0.38, volatiles 0.04, total 100.30%. It resembles actinolite-asbestos in appearance, chrysotile-asbestos (II) in composition, and antigorite in optical properties. X-Ray analysis reveals a peculiar at. arrangement. The dehydration curve shows distinct peaks. (I) is probably an earlier mineral than (II) and grew under conditions of stress. L. S. T.

**Cubanite from [the Frood Mine,] Sudbury, Ontario.** M. A. PEACOCK and G. M. YATSEVITCH (Amer. Min., 1936, 21, 55—62).—The orthorhombic, dipyrarnidal crystals,  $d^{27}$  4.101, hardness 3.5, contain Cu 22.88, Fe 41.41, S 35.35, total 99.64%, in agreement with  $\text{CuFe}_2\text{S}_3$ . The identity of cubanite and chalmersite is confirmed. L. S. T.

**Ganophyllite and zincian amphibole from Franklin Furnace, New Jersey.** W. F. FOSHAG (Amer. Min., 1936, 21, 63—67).—Ganophyllite (I) from this locality has  $\text{SiO}_2$  44.36,  $\text{Al}_2\text{O}_3$  11.40,  $\text{Fe}_2\text{O}_3$  none, FeO 0.09, CaO 2.64, MgO 3.82, MnO 24.24,  $\text{Na}_2\text{O}$  2.86,  $\text{K}_2\text{O}$  0.26,  $\text{H}_2\text{O}$  10.72, total 100.39%, corresponding approx. with  $5\text{MnO} \cdot \text{Al}_2\text{O}_3 \cdot 7\text{SiO}_2 \cdot 5\text{H}_2\text{O}$ ;  $d$  2.878, hardness 3.5,  $n_\alpha$  1.545,  $n_\beta$  1.586,  $n_\gamma$  1.589. Comparison with Swedish (I) shows that the chemical composition is variable. The zincian amphibole closely associated with (I) has  $\text{SiO}_2$  53.20,  $\text{Al}_2\text{O}_3$  5.37,  $\text{Fe}_2\text{O}_3$  8.03, FeO 4.46, MgO 11.12,  $\text{TiO}_2$  0.12, ZnO 4.70, MnO 2.97, CaO 3.36,  $\text{Na}_2\text{O}$  4.35,  $\text{K}_2\text{O}$  0.21,  $\text{H}_2\text{O}$  1.79, total 99.68% corresponding with  $(\text{Na}, \text{Ca}, \text{Zn}, \text{Mn})_3(\text{Mg}, \text{Fe}^{++})_3(\text{Al}, \text{Fe}^{+++})\text{Si}_8\text{O}_{22}(\text{O}, \text{OH})_2$ . L. S. T.

**Felspar twinning in a differentiated sill.** W. M. CHAPMAN (Amer. Min., 1936, 21, 33—47).—A statistical increase in the no. of twins occurs with an increase in basicity, or anorthite content, of the sill. There is apparently no control of, or change in, the type of twinning with the composition of the rock as it appears after crystallisation. An unknown factor and not composition must be responsible for the variation in twinning in different types of rocks. L. S. T.

**Silica-fluorite pseudomorphs.** J. MURDOCH (Amer. Min., 1936, 21, 18—32).— $\text{SiO}_2$ -fluorite pseudomorphs, closely related to intrusions of basalt, occur in Los Angeles County, California. They consist mainly of finely fibrous  $\text{SiO}_2$  and partly of normal quartz (I) grains which may be largely replaced by later fibres. Optical and X-ray examinations show that the apparently different fibrous forms of  $\text{SiO}_2$  are probably due to variant orientations of microcryst. (I). Formation of the pseudomorphs is due to replacement of fluorite from outside, the character of the resultant  $\text{SiO}_2$  depending on the conditions of temp. and concn. at the time of deposition. L. S. T.

**Vesuvianite [and grossularite] from Georgetown, California.** A. PABST (Amer. Min., 1936, 21, 1—10).—Veins of vesuvianite (I) occurring in a serpentine belt along Traverse Creek are described. (I) has  $\text{SiO}_2$  36.60,  $\text{Al}_2\text{O}_3$  19.75,  $\text{Fe}_2\text{O}_3$  0.80, FeO 1.64, MgO 2.58, CaO 37.80,  $\text{H}_2\text{O}$ —0.20,  $\text{H}_2\text{O} +$  0.40,  $\text{TiO}_2$  trace,  $\text{Cr}_2\text{O}_3$  0.18, MnO trace, F,  $\text{CO}_2$ , and Ni none, total 99.95%,  $d_{25}^{25}$  3.326. Spectroscopic traces of Na, B, and V are present. An analysis of grossularite,  $d$  3.5062, is also given. L. S. T.

**Uranium-rich xenotime from Yu, Japan.** S. HATA (Sci. Papers Inst. Phys. Chem. Res. Tokyo, 1936, 29, 37—40).—The specimens showed 5—10 times the normal activity. Physical data and those of a gravimetric analysis are given. The total Ra and  $\text{UO}_2$  content, determined by the emanation method, was Ra ( $10^{-10}$  g.) 9.54,  $\text{UO}_2$  5.28%. A new

method of separating U and Zr consists in dissolving their mixed phosphates in 10%  $\text{H}_2\text{SO}_4$ , the dissolved part being regarded as U, and the remainder as Zr; the correctness of this was confirmed by the emanation data. N. M. B.

**Emanation capacity of ores and rocks of the Taboshar uranium-radium deposit.** A. P. KIRIKOV, T. BOGOSLOVSKAJA, and G. GORSCHKOV (Bull. United Geol. Prospecting Serv. U.S.S.R., 1932, 41, 1293—1299).—The Rn capacity of ores containing yellow U phosphates was considerably > that of torbernite ores. The capacity was greater in  $\text{H}_2\text{O}$  than in air, and increased with fineness of particles. CH. ABS. (e)

**Geological age of bauxite and manganese ore formation in Dunántul (Hungary).** E. VADÁSZ (Bányászati kohászati Lapok, 1935, 68, 163—168, 193—196; Chem. Zentr., 1935, ii, 987).—Both ores are of Lower Cretaceous age. J. S. A.

**Mineral structure of the Ivdel (Ural) bauxite.** F. V. SIROMIATNIKOV (Bull. Soc. nat. Moscow, Sect. geol., 1933, 11, 437—442).—The main components are chamoisite and diasporc, with a small admixture of limonite. The val. as an Al ore is not high. CH. ABS. (e)

**Bababudanite, a soda-amphibole from the banded ferruginous quartzites on Mysore, India.** C. S. PICHAMUTHU (Geol. Mag., 1936, 73, 39—45).—Bababudanite from the Bababudan Hills, Mysore, has  $\text{SiO}_2$  49.80,  $\text{Al}_2\text{O}_3$  1.56,  $\text{Fe}_2\text{O}_3$  18.62, FeO 10.59, MgO 9.30, CaO 0.45,  $\text{Na}_2\text{O}$  8.80,  $\text{K}_2\text{O}$  trace,  $\text{H}_2\text{O}$  0.65, total 99.77%, corresponding with  $4\text{NaFe}^{III}(\text{SiO}_3)_2 \cdot 2\text{FeSiO}_3 \cdot 3\text{MgSiO}_3$  or  $2\text{Na}_2\text{Fe}_2\text{Si}_4\text{O}_{12} \cdot 5(\text{Mg}, \text{Fe}, \text{H}_2, \text{Ca})\text{SiO}_3$ . In chemical and optical properties it is allied to rhodusite. (I) is of contact metamorphic and not primary origin, and is not connected with the origin of the Bababudan iron-stones. L. S. T.

**Geology of an area in the Kavirondo District, Kenya Colony.** W. PULFREY (Geol. Mag., 1936, 73, 26—38).—The greater part of the area is occupied by arenaceous and argillaceous sediments of Muva-Ankolean age. Au occurs in the area as a metasomatic phase of the end stages of the granite intrusion. L. S. T.

**Sulphur deposits of the Sierra de Gádor, Province of Almeria, Spain.** D. WILLIAMS (Bull. Inst. Min. Met., 1936, No. 378, 29 pp.).—Analyses and geology of the S deposits are given and the mode of formation is discussed. D. K. M.

**Gold and silver in crystalline rocks of the Malvern Hills.** A. BRAMMALL and D. L. DOWIE (Min. Mag., 1936, 24, 260—264).—Numerous assays were made of various types of rocks. Appreciable amounts of Au (trace up to 72 grains per ton) and Ag (to 42.4 dwt. per ton) were found only in red granite. L. J. S.

**Silver ores of Freiberg [Saxony].** E. ZIMMER (Tsch. Min. Petr. Mitt., 1936, 47, 328—370).—Polished sections of ores examined by the metallographic method show an intimate intergrowth of various minerals. Argentiferous galena, Zn blende, and pyrite contain minute enclosures of pyrargyrite and

tetrahedrite. A "Weissgiltigerz" containing Ag 4—6% replacing Pb is identified with jamesonite.

L. J. S.

**Microscopic analysis of opaque minerals.** F. L. STILLWELL (Soc. Chem. Ind. Victoria, 1935, 35, 983—987).—Procedure is described.

J. S. A.

**"Chloropal" nontronite ferrosilicates of Satschkovie Chutory.** I. J. MIKEI (Ukrain. Chem. J., 1935, 10, 467—472).—Analytical and other data are recorded.

R. T.

**Dielectric constants of rocks and their dependence on moisture.** N. K. SCHTSCHODRO and N. M. MASLOV (Bull. Acad. Sci. U.R.S.S., 1935, 933—950).—Results are tabulated.

C. W. G.

**Variable composition of cordierite in the Dartmoor granite.** A. BRAMMALL and B. R. RAO (Min. Mag., 1936, 24, 257—259).—The range in optic axial angles ( $2V$  56—82°) shown by different crystals of cordierite suggested a variation in chemical composition. Partial analyses of material fractionated in heavy liquid from the crushed rock gave FeO 4.00—9.10%, MgO 2.07—9.3% (but this variation is not correlated with  $2V$  and  $d$ ).

L. J. S.

**Variability of garnet in granites.** A. BRAMMALL and S. BRACEWELL (Min. Mag., 1936, 24, 254—256).—Two detailed and several partial analyses of manganiferous garnet from the granite of Dartmoor show MnO 3.37—22.00%,  $d$  3.7—4.2. Garnet from the granite of Eskdale, Cumberland, shows MnO 4.15—7.08%,  $d$  < 4.15 to > 4.2.

L. J. S.

**Zeolites. IX. Scolecite and metascolecite.** M. H. HEY [with F. A. BANNISTER] (Min. Mag., 1936, 24, 227—253; cf. A., 1935, 1345).—Two new chemical analyses with detailed crystallographic, optical, and X-ray data are given of scolecite from India and Iceland. Discussed with the best analyses from the lit. these confirm the unit-cell formula  $\text{Ca}_8\text{Al}_{16}\text{Si}_{24}\text{O}_{80}\cdot 24\text{H}_2\text{O}$ , the dimensions of the unit cell being  $a$  18.48,  $b$  18.95,  $c$  6.54 Å.,  $\beta$  89° 21', and the space-group  $S^4$ . Ca may be replaced by  $\text{Na}_2$  to the

extent of 1 atom of Na per unit cell, and by  $\text{K}_2$  about 0.1 atom. The base-exchange products, introducing Na, K, Li,  $\text{NH}_4$ , Ag, and Tl in place of Ca, are in several cases natrolites, confirming the view that natrolite and scolecite are isostructural. V.-p. measurements show that on partial dehydration a transition to metascolecite occurs at a degree of hydration dependent on the temp. and usually before the composition  $\text{CaAl}_2\text{Si}_3\text{O}_{10}\cdot 2\text{H}_2\text{O}$  is reached. In both scolecite and metascolecite the  $\text{H}_2\text{O}$  consists of two distinct groups, in the former a more volatile 16 mols. and a less volatile 8 mols.; and in the latter, a group of 8 mols. is more volatile.

L. J. S.

**Mineralogical composition of the volcanic rocks of Easter Island.** A. LACROIX (Compt. rend., 1936, 202, 527—530).—The rocks are described. Attention is directed to the existence of rhyolites and obsidians.

T. G. P.

**Composition of Easter Island lavas.** A. LACROIX (Compt. rend., 1936, 202, 601—605).—Analyses of plagioclasic rocks are recorded. Basalts and leucocratic types are associated, Na predominating over K even in the most siliceous members (rhyolites and dacitoids). Easter Island therefore belongs to the nepheline-free series of lavas in the author's classification.

L. J. J.

**Volcanic rocks of Pitcairn Island.** A. LACROIX (Compt. rend., 1936, 202, 788—791).—The volcanic rocks of Pitcairn Island are andesites and trachytes and not, as in the neighbouring islands, basalts and oceanites. Analyses of 7 different rocks are given.

M. S. B.

**Mineralisation of the Precambrian of the Anti-Atlas.** F. BLONDEL and J. BONDON (Compt. rend., 1936, 202, 673—674).—The association of Co with Au in this formation has been investigated. Co and Au are distributed independently, Co having been introduced subsequently to the Au, which is associated with intact or dolomitised quartz.

L. J. J.

**Transformation of fatty acids in the course of geological periods.** See this vol., 589.

## Organic Chemistry.

**Electronic theory and organic chemistry. IV. Structure of saturated and unsaturated molecular systems.** V. RASUMOVSKI (Bull. Soc. chim., 1935, [v], 3, 568—580; cf. A., 1935, 431, 843).—The theory developed previously (*loc. cit.*) is applied to open-chain compounds containing contiguous and conjugated ethylenic linkings. It explains the difference in the capacity for reaction of the groups  $\text{Me}$ ,  $\text{CH}_2$ , and  $\text{CH}$  and, in normal, saturated hydrocarbons, the enhanced reactivity of  $\text{CH}_2$  placed towards the end of the chain.

H. W.

**Catalytic production of optically active substances and chemical necessity of a unidirectional course in biochemical processes.** W. KUHN (Angew. Chem., 1936, 49, 215—219).—A lecture.

E. W. W.

**Isomerism and structural theory.** Y. I. GOLDFARB and L. M. SMORGONSKY (J. Chem. Educ., 1936, 13, 22—27).

L. S. T.

[Viscosity of solutions of aliphatic hydrocarbons.] K. H. MEYER and A. VAN DER WYK (Ber., 1936, 69, [B], 545—548; cf. A., 1935, 1318).—A reply to Staudinger (this vol., 309).

H. W.

**Mechanism of oxidation of paraffin hydrocarbons.** A. K. PLISSOV (Bull. Soc. chim., 1936, [v], 3, 425—429).—During atm. oxidation of Grozni paraffin, m.p. 52°, at 120° or 150°, the amount of peroxides (I) formed increases slowly to a max. after 3 hr. and then decreases; after 5—6 hr. (I) are not detectable. (I) are thus not the principal reaction products. In presence of catalysts (Na and Ca salts of naphthenic and higher fatty acids) the concn. of

(I) does not pass through a max. but diminishes steadily and after 4–5 hr. is zero; the catalysts do not, therefore, activate  $O_2$ . (I) are determined by a slight modification of Yule and Wilson's method (B., 1932, 7).

H. B.

**Hexadecane.** P. A. LEVENE (Org. Syntheses, 1935, 15, 27–28).— $C_{16}H_{33}I$  is reduced with Zn and HCl.

CH. ABS. (r)

**Chlorination of paraffins.** H. B. HASS, E. T. MCBEE, and P. WEBER (Ind. Eng. Chem., 1936, 28, 333–339).—The following rules are deduced for the reaction between paraffins and  $Cl_2$ . (1) At  $300^\circ$  in the vapour phase H atoms attached to primary, *sec.*, and *tert.* C are replaced at the relative rates 1.00:3.25:4.43. (2) At rising temp. the relative rates approach unity in both the liquid- and vapour-phase reactions. (3) Liquid-phase chlorination gives relative rates of primary, *sec.*, and *tert.* substitution obtainable only at much higher temp. in the vapour phase. (4) Presence or absence of moisture, C, or light does not appreciably affect the relative rates of substitution. (5) Excessive temp. and/or reaction time results in appreciable pyrolysis of the chloroparaffins in the order primary < *sec.* < *tert.* (6) With a mol. excess of paraffin and const. conditions the yield of monochlorides against polychlorides may be obtained from an equation. (7) Dichlorination proceeds by (a) loss of HCl followed by addition of  $Cl_2$ , and (b) progressive substitution; (a) is favoured by slow, thermal reaction, (b) by rapid liquid- or vapour-phase, single-pass thermal reaction, or low-temp. photochemical conditions. (8) In vapour-phase chlorination the presence of Cl attached to C tends to hinder further substitution on that atom. Herzfelder's rule (cf. A., 1893, i, 449) does not apply to chlorinations. The above rules are illustrated by the calculation of the proportions of isomerides formed by chlorinating  $C_3H_8$ , *n*- and *iso*- $C_4H_{10}$ , *n*- and *iso*- $C_5H_{12}$ .

P. G. C.

**Photo-oxidation of methylene iodide.**—See this vol., 572.

**Dodecyl bromide (lauryl bromide).** E. E. REID, J. R. RUHOFF, and R. E. BURNETT (Org. Syntheses, 1935, 15, 24–26).—The prep. from the alcohol and HBr is described; cyclohexyl, heptyl, tetradecyl, and octadecyl bromides are prepared similarly.

CH. ABS. (r)

**Hexadecyl iodide.** W. W. HARTMAN, J. R. BYERS, and J. B. DICKEY (Org. Syntheses, 1935, 15, 29–30).—The prep. from the alcohol with I and red P is described.

CH. ABS. (r)

**Use of wetting and emulsifying agents [in facilitating reactions].** J. COLONGE (Bull. Soc. chim., 1936, [v], 3, 501–503).—Hydrolysis ( $H_2O$ ) of  $CMc_2Br \cdot CHMeBr$  to  $COMePr^s$  (yield 80%) (cf. Evers *et al.*, A., 1933, 485) occurs much more readily in presence of a little of Twitchell's reagent (I) or Gardinol R (II). (I) also accelerates hydrolysis of  $CH_2[CH(CO_2Et)_2]_2$  to  $CH_2(CH_2 \cdot CO_2H)_2$ . Reduction of  $PhNO_2$  to azoxybenzene is conveniently carried out in presence of (II); the emulsion formed renders shaking unnecessary.

H. B.

**Nitration of gaseous paraffins.** H. B. HASS, E. B. HODGE, and B. M. VANDERBILT (Ind. Eng. Chem., 1936, 28, 339–344).—Nitration was effected in the vapour phase at  $420^\circ$ ;  $CH_4$  is not affected under the conditions used. Some oxidation occurs and probably leads to nitroparaffins of lower C content. The following products are obtained. From  $C_2H_6$ :  $MeNO_2$  (10–20),  $EtNO_2$  (80–90) (total yield, 9%). From  $C_3H_8$ :  $MeNO_2$  (9),  $EtNO_2$  (26?),  $\alpha$ -nitropropane, (I), b.p.  $131^\circ$  (32),  $\beta$ -nitropropane (II), b.p.  $118^\circ$  (33) (total yield, 21%). From *n*- $C_4H_{10}$ :  $MeNO_2$  (6),  $EtNO_2$  (12), (I) (5),  $\alpha$ -nitrobutane, b.p.  $151^\circ$  (27),  $\beta$ -nitrobutane, b.p.  $139^\circ$  (50) (total yield, 28%). From *iso*- $C_4H_{10}$ :  $MeNO_2$  (3), (II) (20),  $\alpha$ -nitroisobutane, b.p.  $140.5^\circ$  (65),  $\beta$ -nitroisobutane (III), b.p.  $126.4^\circ$ , m.p.  $25.6^\circ$  (7),  $COMe_2$  (5) (total yield, 25%). At  $150^\circ$  in sealed tubes *iso*- $C_4H_{10}$  affords 22% of (III). Total yields are practically const. from  $150^\circ$  to  $420^\circ$  if the optimum reaction rate for each temp. is used, but the ratios of isomerides vary, increase of temp. favouring production of primary isomerides. Presence of  $O_2$  results in increased oxidation. Increase of pressure increases reaction rate and yields (slightly). With the exception of  $MeNO_2$ , the nitroparaffins could not be exploded; they are stable, non-toxic, good solvents for gums and resins, and can be used in admixture with alcohols as solvents for cellulose nitrate.

P. G. C.

**Determination of the terminal methylene group.** J. DŒUVRE (Bull. Soc. chim., 1936, [v], 3, 612–620).—A very dil. solution of the substance in  $EtOAc$ – $AcOH$  (3:2) is treated with  $O_3$  (about 5%) at  $-15^\circ$  to  $-20^\circ$ , excess of  $O_3$  being avoided. The ozonide is reduced by  $SO_2$  and  $CH_2O$  determined colorimetrically (Denigès). Substances containing the groups  $CH_2 \cdot CMe$ ,  $CH_2 \cdot CH \cdot CH_2$ , and  $CH_2 \cdot CH$  give, respectively, 90–95%, 75–90%, and about 50% of the expected amounts of  $CH_2O$ . Two conjugated  $CH_2$  groups behave as a single group. Unsaturated compounds devoid of  $\cdot CH_2$  give only negligible amounts of  $CH_2O$ . *Acraldehyde-2:4-dinitrophenylhydrazones* has m.p.  $184^\circ$ .

H. W.

**Olefine formation.** W. TAYLOR (Chem. and Ind., 1936, 275–276).—Polemical against Ingold *et al.* (this vol., 433). The author claims that his results (A., 1935, 1465; cf. Olivier, *ibid.* 62) first made possible a general theory of olefine formation.

J. W. B.

**Ring tension of cyclenes.** J. BÖSEKEN and J. STUURMAN (Proc. K. Akad. Wetensch. Amsterdam, 1936, 39, 2–9; cf. A., 1935, 1103).—Vals. of *E* and *B* obtained from  $\log_e k = -E/RT + B$  are given for the interaction of  $C_2H_4$ ,  $C_3H_6$ ,  $CHPr^s \cdot CH_2$ ,  $CHBu^s \cdot CH_2$ ,  $CH_2Ph \cdot CH \cdot CH_2$ ,  $CMc_2 \cdot CH_2$ ,  $CHEt \cdot CHMe$ ,  $CHPr^s \cdot CHMe$ ,  $CHEt \cdot CHEt$ ,  $CHPh \cdot CHMe$ ,  $CPh_2 \cdot CH_2$ ,  $CHPh \cdot CHPh$ ,  $CMc_2 \cdot CHMe$ ,  $CPh_2 \cdot CHPh$ ,  $CHPh \cdot CH_2$ , cyclohexene, cyclopentene, cyclobutene, indene, 1:2- and 1:4-dihydronaphthalene, and methylcyclopentene, respectively, with  $AcO_2H$ .

R. S.

**Gutta-percha hydrocarbon.** Amorphous rubber.—See this vol., 553.

**Preparation and properties of an  $\alpha\gamma$ -disubstituted allene:  $\Delta^{\beta\gamma}$ -hexadiene.** H. VAN RIS-

SEGHEM (Bull. Soc. chim. Belg., 1936, 45, 95—96; cf. this vol., 187).—Corrigenda. The hydrocarbon, b.p. 67·75—68·25°, as shown by its Raman spectrum, is not an allene, but a mixture of *cis*- and *trans*-isomerides of a disubstituted ethylene. The Br-compound, b.p. 49·0—49·2°/26 mm., is fully saturated and does not absorb Br or H<sub>2</sub>. J. L. D.

**Dehydration of methyl ditert.-butylcarbinol. Fission and isomerisation of ditert.-butylethylene.** N. NAZAROV (Compt. rend. Acad. Sci. U.R.S.S., 1936, 1, 79—82; cf. A., 1933, 1271).—CMeBu<sup>t</sup><sub>2</sub>·OH when distilled with I gives CBut<sup>t</sup><sub>2</sub>:CH<sub>2</sub> (cf. A., 1933, 1140), which when distilled with 1:4-C<sub>10</sub>H<sub>6</sub>Br·SO<sub>3</sub>H (A., 1935, 62) gives CMe<sub>2</sub>:CH<sub>2</sub> along with CMe<sub>2</sub>:CMe<sub>2</sub>, CMePr<sup>β</sup>:CH<sub>2</sub>, and CHBu<sup>t</sup>:CH<sub>2</sub>. The origin of these products is discussed. J. L. D.

**Direct production of organic compounds containing artificial radio-elements.** E. GLÜCKAUF and J. W. J. FAX (J.C.S., 1936, 390—393).—When org. halogen compounds are irradiated with slow neutrons, all the halogen atoms activated are ejected and then enter other mols., replacing other halogens, OH, NH<sub>2</sub>, CO<sub>2</sub>H, or CH<sub>2</sub>·OH. Some of the newly formed compounds can be separated with high activity. In the following experiments the figure in parentheses is the % of the total activity which is found in the reaction product named. MeI gives CH<sub>3</sub>I<sub>2</sub> (11). CH<sub>3</sub>Br<sub>2</sub> gives CHBr<sub>3</sub> (14). CHBr<sub>3</sub> gives CBr<sub>4</sub> (19). PhCl gives C<sub>6</sub>H<sub>4</sub>Cl<sub>2</sub> (15). CH<sub>3</sub>Br·CO<sub>2</sub>H gives CH<sub>2</sub>Br<sub>2</sub> (22). EtOH—I (saturated) gives MeI (6) and EtI (4). AcOH—I (saturated) gives MeI (10). C<sub>6</sub>H<sub>6</sub>·CCl<sub>4</sub> (1:1) gives PhCl (10). C<sub>6</sub>H<sub>6</sub>·CBr<sub>4</sub> (1:1) gives PhBr (15). PhOH·MeBr (1:1) gives MeBr (6), PhBr (2), and C<sub>6</sub>H<sub>4</sub>Br·OH (2). NH<sub>2</sub>Ph·HBr gives PhBr (1) and C<sub>6</sub>H<sub>4</sub>Br·OH (2). C<sub>6</sub>H<sub>6</sub>·MeI (10:1) gives PhI (15). Since often relatively small amounts of the products are isolated, the degree of activity contained in them is often very high. MeI gives the same result at -175° as at room temp., so that exchange of atoms is not due to ordinary chemical action; moreover, large dilution with an inert material (e.g., CHBr<sub>3</sub> with CS<sub>2</sub>) prevents formation of the active product (e.g., CBr<sub>4</sub>), because no mols. are available for collision. If air saturated with MeI is passed through KI-80% AcOH which is irradiated, highly active MeI is collected from the issuing air in a liquid air trap; no material is used up in this transformation, which can proceed indefinitely. An experiment under modified conditions shows that < 80% of the activity is due to slow neutrons.

R. S. C.

**Allylic rearrangements. III. Action of zinc on crotyl and methylvinylcarbinyl bromides.** W. G. YOUNG and S. WINSTEIN (J. Amer. Chem. Soc., 1936, 58, 441—443).—Reduction (Zn dust, boiling aq. EtOH) of various mixtures of CHMe:CH·CH<sub>2</sub>Br and CH<sub>3</sub>:CH·CHMeBr gives the same mixture of Δ<sup>a</sup>- (62·1±1·9%) and Δ<sup>β</sup>- (30·5±0·5% *cis* and 7·5±2·4% *trans*) -butene, the composition of which differs somewhat from that of the mixture obtained (this vol., 451) from the Grignard reagent.

H. B.

**Electron in organic chemistry. IV. Monohydroxy-compounds.** M. S. KHARASCH, O. REIN-

MUTH, and F. R. MAYO (J. Chem. Educ., 1936, 13, 7—19; cf. *ibid.*, 1934, 11, 82). L. S. T.

**Catalytic decomposition of alcohols.**—See this vol., 571.

**Thermal decomposition of ethylene oxide and an induced acetaldehyde decomposition.**—See this vol., 570.

**Preparation and properties of keten diethyl acetal.** F. BEYERSTEDT and S. M. McELVAIN (J. Amer. Chem. Soc., 1936, 58, 529—531; cf. A., 1933, 258, 259).—Attempts to prepare keten Et<sub>2</sub> acetal (I) by Scheibler's modified procedure (A., 1933, 377) were unsuccessful. (I), b.p. 124—126°, is now prepared in 52% yield from CH<sub>2</sub>I·CH(OEt)<sub>2</sub> (II), b.p. 69—70°/8 mm. [from CH<sub>2</sub>Br·CH(OEt)<sub>2</sub> (III) and NaI in COMe<sub>2</sub> at 110°], and boiling Bu<sup>t</sup>OH·KOBu<sup>t</sup>. (I) reacts rapidly and exothermically with H<sub>2</sub>O and EtOH at room temp. yielding EtOAc and CMe(OEt)<sub>3</sub>, respectively. Polymerisation of (I) occurs slowly at room temp. and is accelerated by heat. Reduction [H<sub>2</sub> (2000 lb.), Raney Ni, Et<sub>2</sub>O, 100°] of (I) occurs rapidly and gives CHMe(OEt)<sub>2</sub> (35%); much polymerised (I), which inactivates the catalyst, is also formed. CH<sub>2</sub>Cl·CH(OEt)<sub>2</sub> and EtOH·KOH (10% excess) at 150° give 95% of OH·CH<sub>2</sub>·CH(OEt)<sub>2</sub> (IV); (III) similarly affords (at 130°) (IV) (70%) and EtOAc (24%), whilst (II) yields (IV) (30%), EtOAc (23%), and CMe(OEt)<sub>3</sub> (42%). (II) and EtOH·NaOEt give OEt·CH<sub>2</sub>·CH(OEt)<sub>2</sub> (30%), EtOAc (21%), and CMe(OEt)<sub>3</sub> (46%). (I) is undoubtedly formed in these reactions with (II) but it then reacts with H<sub>2</sub>O and EtOH. H. B.

**Trichloroethyl alcohol.** W. CHALMERS (Org. Syntheses, 1935, 15, 80—84).—Al(OEt)<sub>3</sub> and CCl<sub>3</sub>·CHO afford Al(O·CH<sub>2</sub>·CCl<sub>3</sub>)<sub>3</sub>, which is hydrolysed to CCl<sub>3</sub>·CH<sub>2</sub>·OH. CH. ABS. (r)

**Biochemical hydrogenations. III. Hydrogenation of conjugated double linkings by fermenting yeast.** F. G. FISCHER and O. WIEDEMANN (Annalen, 1936, 522, 1—16).—The hydrogenation (method: A., 1935, 123) of conjugated systems containing ·CH:CH·CO· or ·CH:CH·CH<sub>2</sub>·OH results in α-β-addition and differs (cf. below) from reduction with Na or Na-Hg. Thus, the hexenol (I) obtained (*loc. cit.*) from Δ<sup>αγ</sup>-hexadienal (II) or Δ<sup>βδ</sup>-hexadien-α-ol (III) is essentially Δ<sup>δ</sup>-hexen-α-ol (IV), since careful ozonolysis in cold EtCl and subsequent reductive fission (Zn, AcOH) gives MeCHO (0·72—0·84 mol.) and (after oxidation of non-volatile residue with KMnO<sub>4</sub> in aq. Na<sub>2</sub>CO<sub>3</sub>) succinic acid (V) (0·76—0·82 mol.). Oxidation (KMnO<sub>4</sub>, aq. Na<sub>2</sub>CO<sub>3</sub>) of (I) affords AcOH (≠ 0·6 mol.) and (V) (≠ 50%). The octadienol previously described (*loc. cit.*) is Δ<sup>αδ</sup>-octadien-α-ol since it is oxidised (KMnO<sub>4</sub>, COMe<sub>2</sub>) to (V) (66—77%). CHMe:CH·CH:CH·COMe (VI) is hydrogenated (cf. *ibid.*, 1367) to Δ<sup>α</sup>-hepten-β-one (ozonolysis products, MeCHO and levulaldehyde) and -β-ol (ozonolysis products, MeCHO and γ-hydroxyvaleraldehyde), whilst CHPh:CH·CH:CH·COMe (VII) similarly gives (cf. *loc. cit.*) ζ-phenyl-Δ<sup>α</sup>-hexen-β-one and -β-ol, which are oxidised (O<sub>3</sub> followed by H<sub>2</sub>O<sub>2</sub>) to BzOH and levulic acid.

Reduction (Na, MeOH) of (III) gives approx. 33% of

(IV) and 66% of  $\Delta^2$ -hexen- $\alpha$ -ol; undistillable products are obtained from (II) and Na- or Al-Hg. (VI) is reduced (3% Na-Hg, EtOH) to mainly  $\Delta^8$ -hepten- $\beta$ -one (ozonolysis products, EtCHO and  $\text{CH}_3\text{Ac}\cdot\text{CHO}$ ), whilst (VII) and Na-Hg in EtOH-AcOH afford  $\zeta$ -phenyl- $\Delta^8$ -hexen- $\beta$ -one (ozonolysis products,  $\text{CH}_2\text{Ph}\cdot\text{CHO}$  and  $\text{CH}_3\text{Ac}\cdot\text{CHO}$ ) and products of higher mol. wt.

H. B.

**Dibutylcarbinol.** G. H. COLEMAN and D. CRAIG (Org. Syntheses, 1935, 15, 11-13).—The prep. from  $\text{MgBuBr}$  and  $\text{HCO}_2\text{Et}$  is described.

CH. ABS. (r)

**Oleyl alcohol** ( $\Delta^9$ -octadecenol). E. E. REID, F. O. COCKERILLE, J. D. MEYER, W. M. COX, jun., and J. R. RUHOFF (Org. Syntheses, 1935, 15, 51-54).—The reduction of  $\text{C}_{17}\text{H}_{33}\cdot\text{CO}_2\text{Bu}$  with  $\text{NaOBu}$  is described.

CH. ABS. (r)

**General method for preparation of  $\alpha\alpha'$ -diethyl- $\epsilon$ -nic glycols,  $\text{OH}\cdot\text{CHR}\cdot\text{CHR}\cdot\text{OH}$ .** Conversion of some of these glycols into sugars. J. WIEMANN (Ann. Chim., 1936, [xi], 5, 267-336).—By the method previously described (A., 1935, 608, 963) the following were obtained:  $\Delta^{\alpha\epsilon}$ -heptadiene- $\gamma\delta$ -diol (two phenylurethanes, m.p. 151.5-152° and 160°);  $\epsilon$ -phenyl- $\Delta^{\beta\epsilon}$ -pentene- $\delta\epsilon$ -diol, b.p. 139°/2 mm.;  $\gamma\zeta$ -dimethyl- $\Delta^{\beta\epsilon}$ -octadiene- $\delta\epsilon$ -diols, b.p. 133-135°/12 mm., m.p. 36-38°, and b.p. 133-135°/12 mm.;  $\delta\eta$ -dimethyl- $\Delta^{\gamma\epsilon}$ -decadiene- $\epsilon\zeta$ -diols, m.p. 72-73° and b.p. 148-149°/12 mm. [not identical with the compound, m.p. 89.5°, described by von Lenz (A., 1903, i, 460)];  $\epsilon$ -methyl- $\Delta^{\alpha\epsilon}$ -heptadiene- $\gamma\delta$ -diol, b.p. 116-117°/12 mm.;  $\zeta$ -methyl- $\Delta^{\beta\epsilon}$ -octadiene- $\delta\epsilon$ -diol, b.p. 124-125°/12 mm.;  $\zeta$ -methyl- $\Delta^{\beta\epsilon}$ -nonadiene- $\delta\epsilon$ -diol, b.p. 130-131°/12 mm.;  $\gamma\zeta$ -dimethyl- $\Delta^{\beta\epsilon}$ -nonadiene- $\delta\epsilon$ -diol, b.p. 140-141.5°/12 mm. A mixture of two isomeric  $\Delta^{\beta\epsilon}$ -octadiene- $\delta\epsilon$ -diols (Charon, A., 1899, i, 848) was separated by fractional crystallisation of phenylurethanes from EtOH into *dl*- and *meso*-forms, m.p. 23-24° (phenylurethane, m.p. 168°) and 48° (phenylurethane, m.p. 190°), respectively. The *dl*- and *meso*-forms of  $\Delta^{\alpha\epsilon}$ -hexadiene- $\gamma\delta$ -diol previously separated by Romburgh *et al.* (A., 1932, 718) have m.p. 14° (phenylurethane, m.p. 124°) and 17-18° (phenylurethane, m.p. 181°). A more detailed account is also given of the oxidation of these glycols (A., 1932, 718; 1933, 47; 1935, 605, 1104). *d* and *n*<sub>D</sub> for the above compounds are recorded.

F. R. G.

**Hexose monophosphates. Glucose 4-phosphate.** A. L. RAYMOND (J. Biol. Chem., 1936, 113, 375-382).—Benzylideneglucose when heated with  $\text{AcOH}\cdot\text{NaOAc}$  affords  $\alpha$ - (sol. in 95% EtOH) and  $\beta$ -4 : 6-benzylideneglucose triacetate (insol.), converted by hydrolysis ( $\text{HCl}$ -aq.  $\text{COMe}_3$ ) and subsequent acetylation ( $\text{Ac}_2\text{O}\cdot\text{C}_5\text{H}_5\text{N}$  in  $\text{CHCl}_3$ ) into  $\beta$ -glucose 1 : 2 : 3 : 6-tetra-acetate (Helfferich *et al.*, A., 1927, 135), which with  $\text{POCl}_3\cdot\text{C}_5\text{H}_5\text{N}$  in dry  $\text{CHCl}_3$  at -30° to 0° followed by hydrolysis with  $\text{Ba(OH)}_2$  gives glucose 4-phosphate (I) (*Ba* salt), isolated as its *dibrucine* salt, [ $\alpha$ ]<sub>D</sub><sup>25</sup> -45.3° in  $\text{C}_5\text{H}_5\text{N}$ . (I) behaves differently from the 3- and 6-phosphates: it gives no osazone, but its *Ba* H salt gives an *osazone*: the course of glucoside formation (at room temp. and at 76°) differs from that of the 3- and 6-phosphates (Levene *et al.*, A.,

1929, 423), but is related to that of tetramethyl-glucopyranose. At low concns. (0.005, 0.02*M*) the rate of fermentation of the Na salt of (I) with zymine (*p*<sub>H</sub> 6.4) is negligible, and both in the presence and absence of glucose and of hexose diphosphate, no reduction in the induction period occurs. At higher concn. (0.06*M*) (I) has an inhibiting effect on fermentation.

J. W. B.

**Alkane- $\alpha\omega$ -disulphonates.** G. C. H. STONE (J. Amer. Chem. Soc., 1936, 58, 488-489).—

$(\text{CH}_2)_n(\text{SO}_3\text{Na})_2$  are prepared in 30-50% yield from  $(\text{CH}_2)_n\text{Br}_2$  (1 mol.) and saturated aq.  $\text{Na}_2\text{SO}_3$  (2.5 mols.) at 100° (bath). *Na ethylene-* and *tri-, tetra-, penta-, hexa-, and deca-methylene-disulphonates* are described. Titration curves of  $(\text{CH}_2)_n(\text{SO}_3\text{H})_2$  are identical with that of  $\text{H}_2\text{SO}_4$ . *Decamethylene dibromide* has b.p. 161-162°/10 mm., f.p. 25-26°.

H. B.

**Tautomerism of butadiene sulphone.** J. BÖSEKEN and E. DE ROY VAN ZUYDEWIJN (Proc. K. Akad. Wetensch. Amsterdam, 1936, 39, 31; cf. A., 1935, 326).—Treatment of butadiene sulphone

with KOH gives  $\text{HO}\cdot\text{CH}\cdot\text{CH}_2\text{CH}_2\cdot\text{SO}_2$  (I), m.p. 35° (*Ac* derivative, m.p. 74-75.5°). Irradiation of (I) in presence of aq. KOH does not yield  $\alpha$ - or  $\beta$ -butadiene sulphone (cf. Backer *et al.*, A., 1935, 1105). R. S.

**Organic catalysts. XIII. Esterase models.** W. LANGENBECK and F. BAEHREN (Ber., 1936, 69, [B], 514-520; cf. this vol., 476).—Measurements of the rate of hydrolysis of  $\text{Pr}^c\text{CO}_2\text{Me}$  alone and in presence of  $\text{CH}_2\text{Bz}\cdot\text{OH}$ , 1- or 2- $\text{C}_{10}\text{H}_7\cdot\text{CO}\cdot\text{CH}_2\cdot\text{OH}$ ,  $\text{OH}\cdot\text{CH}_2\cdot\text{CO}\cdot\text{NHPh}$ , and 1- or 2- $\text{C}_{10}\text{H}_7\cdot\text{NH}\cdot\text{CO}\cdot\text{CH}_2\cdot\text{OH}$  by a modified technique are recorded whereby the last-named substance is shown to be the most active catalyst. The previous hypothesis that hydrolysis is preceded by alkyl exchange,  $\text{Pr}^c\text{CO}_2\text{Me} + \text{CH}_2\text{Bz}\cdot\text{OH} \rightarrow \text{Pr}^c\text{CO}_2\text{CH}_2\text{Bz}$  (I) +  $\text{MeOH}$  and (I) +  $\text{H}_2\text{O} \rightarrow \text{Pr}^c\text{CO}_2\text{H} + \text{CH}_2\text{Bz}\cdot\text{OH}$ , is supported by the observed rate of hydrolysis of esters (I), so that it appears that the alkyl exchange is the slowest part of the total reaction. Gradual addition of 3 : 2- $\text{OAc}\cdot\text{C}_{10}\text{H}_6\cdot\text{COCl}$  in anhyd.  $\text{Et}_2\text{O}$  to  $\text{CH}_2\text{N}_2$  in  $\text{Et}_2\text{O}$  at 0° affords 3-acetoxy-2-naphthyl diazomethyl ketone, m.p. 120-121°, converted by  $\text{HCl}$  in  $\text{Et}_2\text{O}$  into 3-acetoxy-2-naphthyl  $\text{CH}_2\text{Cl}$  ketone, m.p. 90-91°, by warm  $\text{AcOH}$  into 3-acetoxy-2-naphthoylecarbinyl acetate, m.p. 127°, and by boiling 50%  $\text{AcOH}$  into 3-acetoxy-2-naphthoylecarbinol, m.p. 117°. 6 : 2- $\text{OAc}\cdot\text{C}_{10}\text{H}_6\cdot\text{CO}_2\text{H}$  and  $\text{PCl}_5$  in ligroin afford 6-acetoxy-2-naphthoyle chloride, m.p. 124°, whence 6-acetoxy-2-naphthyl diazomethyl ketone, m.p. 123°, 6-acetoxy-2-naphthyl  $\text{CH}_2\text{Cl}$  ketone, m.p. 112°, and 6-acetoxy-2-naphthoylecarbinyl acetate, m.p. 112°. 1 : 2- $\text{OH}\cdot\text{C}_{10}\text{H}_6\cdot\text{CO}_2\text{H}$  does not appear to be affected by  $\text{NaOAc}$  and boiling  $\text{Ac}_2\text{O}$  and is resinified by  $\text{Ac}_2\text{O}$  containing a little conc.  $\text{H}_2\text{SO}_4$ . H. W.

**Transformation of fatty acids in the course of geological periods.** G. STADNIKOV and O. EGOROVA (Brennstoff-Chem., 1936, 17, 48-49; cf. A., 1933, 928).—The residue obtained after extraction of baltashite with org. solvents was dissolved by heating with 2% aq.  $\text{NaOH}$ /25 atm. On acidifying the solution the acids separated as a clear yellow liquid, which rapidly changed into a viscous dark brown

mass insol. in org. solvents. On acidifying the solution in presence of  $\text{Et}_2\text{O}$  the acids dissolved therein, but subsequently changed into the insol. form. This tendency to change was diminished by heating the balkashite residue with the aq.  $\text{NaOH}$  under high  $\text{H}_2$  pressure. It is concluded that the conversion into a viscous or rubber-like form is not a polymerisation, but a colloid-chemical process similar to the conversion of humic acids into the insol. form by ageing.

A. B. M.

**Interaction of carbon monoxide and alcohols.**

**II. Synthesis of propionic and isobutyric acids.**  
**III. Synthesis of methylethylacetic and pivalic acids.** D. V. N. HARDY (J.C.S., 1936, 358—362, 362—364; cf. A., 1934, 1200).—II. In presence of  $\text{H}_3\text{PO}_4\text{-Cu}_3(\text{PO}_4)_2$ ,  $\text{EtOH}$  and  $\text{CO}$  at  $250\text{--}370^\circ$  give 3.7% of  $\text{EtCO}_2\text{H}$ , 2% of  $\text{EtCO}_2\text{Et}$ , and 8—24% of polymerised  $\text{C}_2\text{H}_4$ , the % of polymerides rising rapidly with rising temp.  $\text{Pr}^\alpha\text{OH}$  and  $\text{Pr}^\beta\text{OH}$  react at  $150\text{--}300^\circ$  to give  $\text{Pr}^\beta\text{CO}_2\text{H}$  (max. about 30—33% at  $210^\circ$ ) (no  $\text{Pr}^\alpha\text{CO}_2\text{H}$ ), small amounts of esters, much higher acids (mainly  $\text{C}_{3n}\text{H}_{6n+1}\cdot\text{CO}_2\text{H}$ ), and polymerised hydrocarbons,  $\text{C}_3\text{H}_6$ , and some  $\text{COMeBu}^\beta$  and  $\text{COPr}^\beta$ . It is concluded that reaction occurs by preliminary dehydration of the alcohol, and, in conformity with this view,  $\text{Pr}^\beta\text{OH}$ , being more readily dehydrated, reacts more completely than does  $\text{Pr}^\alpha\text{OH}$ . The ketones are formed by two routes, (i) condensation of alcohol or olefine to higher alcohol and dehydrogenation, and (ii) loss of  $\text{CO}_2$  from acids formed.

**III.** In presence of  $\text{H}_3\text{PO}_4$  with or without  $\text{Cu}_3(\text{PO}_4)_2$  at  $200\text{--}210^\circ$   $\text{Bu}^\alpha\text{OH}$  or  $\text{Bu}^\beta\text{OH}$  and  $\text{CO}$  give much  $\text{Bu}^\gamma\text{CO}_2\text{H}$ , a little  $\text{CHMeEt}\cdot\text{CO}_2\text{H}$ , large amounts of a mixture,  $\text{C}_8\text{H}_{17}\cdot\text{CO}_2\text{H}$ , and polymerised hydrocarbons.  $\text{CHMeEt}\cdot\text{OH}$  gives similar products, except that only traces of  $\text{CHMeEt}\cdot\text{CO}_2\text{H}$  are formed. Reaction occurs only by way of the butylenes, which are interconvertible under the conditions used.

R. S. C.

**Interaction of olefines, carbon monoxide, and steam.** D. V. N. HARDY (J.C.S., 1936, 364—365).—At  $290\text{--}300^\circ/150$  atm. in presence of  $\text{H}_3\text{PO}_4$ ,  $\text{C}_2\text{H}_4$ ,  $\text{CO}$ , and  $\text{H}_2\text{O}$  give  $\text{EtCO}_2\text{H}$  (1 mol.),  $\text{EtOH}$  (3 mols.), and polymerised hydrocarbons (2 mols.). At  $200^\circ/200$  atm.  $\text{C}_3\text{H}_6$  gives similarly much  $\text{Pr}^\gamma\text{CO}_2\text{H}$  and homologues; and  $(\text{CHMe})_2$  gives  $\text{Bu}^\gamma\text{CO}_2\text{H}$  and other acids and some  $\text{CHMeEt}\cdot\text{CO}_2\text{H}$ . These reactions exactly resemble those with alcohols (preceding abstract) and confirm the mechanism suggested. For reaction the olefine must be activated; in presence of  $\text{H}_3\text{PO}_4$  activation occurs by formation and decomp. of alkyl phosphates.

R. S. C.

**Elaidinisation of oleic acid and cis-trans isomerism.** J. STUURMAN (Chem. Weekblad, 1936, 33, 201, 255).—Polemical against Bertram (this vol., 189, and below).

D. R. D.

**Elaidinisation of oleic acid and cis-trans isomerism.** S. H. BERTRAM (Chem. Weekblad, 1936, 33, 216, 255).—Replies to Stuurman (preceding abstract).

S. C.

**Telfairic acid.** G. D. GOODALL and R. D. HAWORTH (J.C.S., 1936, 399).—Telfairic acid (A., 1900, i, 473) from the seeds of *Telfairia pedata* is really linoleic acid.

R. S. C.

**Ketolic condensations of ethyl acetoacetate with acetaldehyde.** H. GAULT and T. WENDLING (Bull. Soc. chim., 1936, [v], 3, 369—388).—Partly a more detailed account of work previously reviewed (A., 1935, 65). The following appears to be new. **Et di- $\alpha'$ -hydroxyethylacetoacetate (I)** is decomposed by  $\text{PhNCO}$ ; **Et ethylideneacetoacetate (II)** and resinous products are formed. (I) and  $\text{AcCl}$  give an unstable  $\text{Cl}$ -containing compound, b.p.  $104\text{--}105^\circ/14$  mm.; in presence of  $\text{C}_5\text{H}_5\text{N}$ , (II) results. Decomp. of (I) also occurs with  $\text{BzCl}$  (in  $\text{C}_5\text{H}_5\text{N}$ ) or  $\text{Ac}_2\text{O}$ ;  $\text{EtOH}\cdot\text{NH}_3$  leads to  $\text{MeCHO}\cdot\text{NH}_3$  and resin. Attempted prep. of a pyrazolone and phenylhydrazone from (I) gives the corresponding derivatives (*loc. cit.*) of **Et  $\alpha'$ -hydroxyethylacetoacetate (III)**. The stability of (III), alone and in various solvents, is studied. (III) is dehydrated ( $\text{H}_3\text{PO}_4$ ) to (II).

H. B.

**Ketolic condensations of ethyl acetoacetate with acetaldehyde.** H. GAULT and T. WENDLING (Bull. Soc. chim., 1936, [v], 3, 549—568; cf. preceding abstract).— $\text{OH}\cdot\text{CHMe}\cdot\text{CHAc}\cdot\text{CO}_2\text{Et}$  (I) appears to be dehydrated and resinified by  $\text{PhNCO}$  in  $\text{Et}_2\text{O}$ . With  $\text{AcCl}$  it affords an unstable compound, probably  $\text{CEtAcCl}\cdot\text{CO}_2\text{Et}$ , b.p.  $109\text{--}112^\circ/17$  mm., whereas it is dehydrated by  $\text{Ac}_2\text{O}$  and  $\text{NaOAc}$  to **Et ethylideneacetoacetate**. With  $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$  in  $\text{EtOH}$  (I) yields **3-methyl-4- $\alpha$ -hydroxyethylpyrazol-5-one**, m.p.  $275^\circ$ , whilst with  $\text{NHPh}\cdot\text{NH}_2$  in  $\text{EtOH}$  it gives the **phenylhydrazone**, m.p.  $92^\circ$ , which loses  $\text{MeCHO}$  and resinifies when heated. (I) is resinified by  $\text{NH}_2\cdot\text{CO}\cdot\text{NH}_2\cdot\text{NH}_2$ . Alkaline or acidic hydrolysis of (I) does not give well-defined results, whilst  $\text{EtOH}\cdot\text{NH}_3$  gives  $\text{MeCHO}\cdot\text{NH}_3$ . (I) with  $\text{CH}_2\text{O}$  in presence of  $\text{K}_2\text{CO}_3$  and  $\text{H}_2\text{O}$  gives a mixture of products from which **Et<sub>2</sub>  $\alpha,\epsilon$ -dihydroxy- $\beta\delta$ -diacetylpentane- $\beta\delta$ -dicarboxylate**, m.p.  $97^\circ$ , is isolated; with  $\text{MeCHO}$  **Et di- $\alpha'$ -hydroxyethylacetoacetate** is produced. (I) and  $\text{CH}_2\text{Ac}\cdot\text{CO}_2\text{Et}$  in presence of  $\text{NHEt}_2\cdot\text{EtOH}$  afford **Et<sub>2</sub> 2-hydroxy-2 : 6-dimethylcyclohexan-4-one-1 : 6-dicarboxylate**, m.p.  $78\text{--}79^\circ$ . (I) and  $\text{NHEt}_2$  at  $-10^\circ$  give crude **Et<sub>2</sub>  $\epsilon$ -hydroxy- $\gamma$ -diacetyl- $\beta$ -methylpentane- $\alpha\gamma$ -dicarboxylate**, identified by conversion into the **dipyrazolone**,  

$$\begin{array}{c} \text{NH}\cdot\text{CO} \\ \text{N}=\text{CMe} \end{array} \text{CH}\cdot\text{CHMe}\cdot\text{C}(\text{CHMe}\cdot\text{OH}) \begin{array}{c} \text{CO}\cdot\text{NH} \\ \text{CMe}\cdot\text{N} \end{array}$$
 m.p.  $267\text{--}268^\circ$ .

H. W.

**Ferric oxalate.**—See this vol., 576.

**Polymembered heterocyclic compounds. IX. Polymembered cyclic esters from dihydric alcohols and dicarboxylic acids.** M. STOLL and A. ROUVÉ (Helv. Chim. Acta, 1936, 19, 253—261; cf. A., 1935, 1351).—The relative ease of formation of various polymembered cyclic lactones, di- and tri-lactones is in harmony with probability considerations if the effect of change of mol. concn. is taken into account.  $\text{OH}\cdot[\text{CH}_2]_9\cdot\text{OH}$  and  $\text{CO}_2\text{H}\cdot[\text{CH}_2]_7\cdot\text{CO}_2\text{H}$  in 0.005*M* solution give **di-** (I),  $\text{CO} < \begin{array}{c} \text{O} \\ | \\ [\text{CH}_2]_9 \end{array} > \text{CO}$ , m.p.  $10\text{--}12^\circ$ , b.p.  $147\text{--}148^\circ/0.01$  mm., and **tetra-lactone** (II),  $\text{CO} < \begin{array}{c} \text{O} \\ | \\ [\text{CH}_2]_9 \end{array} \text{O}\cdot\text{CO} < \begin{array}{c} \text{O} \\ | \\ [\text{CH}_2]_7 \end{array} > \text{CO}$ , m.p.  $65\text{--}68^\circ$ ; the ratio, (I) : (II) = 46 : 54, is < expected from the lactonisation of  $\text{OH}\cdot[\text{CH}_2]_3\cdot\text{CO}_2\text{H}$ ; this is attributed to formation of more highly complex esters.

$\text{OH} \cdot [\text{CH}_2]_3 \cdot \text{OH}$ ,  $\text{CO}_2\text{H} \cdot [\text{CH}_2]_3 \cdot \text{CO}_2\text{H}$ , and anhyd.  $\text{PhSO}_3\text{H}$  give the *di*-,  $\text{CO} \cdot \text{O} \cdot \text{O} \cdot [\text{CH}_2]_3 \cdot \text{CO}$ , m.p. 14–17°, b.p. 100–102°/0.02 mm., and *tetra-lactone*,  $\text{CO} \cdot \text{O} \cdot [\text{CH}_2]_3 \cdot \text{CO}_2 \cdot [\text{CH}_2]_3 \cdot \text{O} \cdot \text{CO} \cdot [\text{CH}_2]_3 \cdot \text{O} \cdot \text{CO}$ , m.p. 113–113.5°, but 70% of the material is converted by primary esterification of the  $\text{PhSO}_3\text{H}$  into the *esters*,  $\text{SO}_3\text{Ph} \cdot \text{O} \cdot [\text{CH}_2]_3 \cdot \text{O} \cdot \text{CO} \cdot [\text{CH}_2]_3 \cdot \text{CO}_2 \cdot [\text{CH}_2]_3 \cdot \text{OH}$ , an oil, and  $\text{CO}_2\text{H} \cdot [\text{CH}_2]_3 \cdot \text{CO}_2 \cdot [\text{CH}_2]_3 \cdot \text{O} \cdot \text{CO} \cdot [\text{CH}_2]_3 \cdot \text{CO}_2 \cdot [\text{CH}_2]_3 \cdot \text{O} \cdot \text{SO}_2\text{Ph}$  (not obtained pure), a glass. R. S. C.

Two crystalline *d*-talomucolactones. (FRL.) M. STEIGER and T. REICHSTEIN (Helv. Chim. Acta, 1936, 19, 195–203).—*d*-Talomucic acid (modified prep. from *d*-talonic acid), m.p. 155–158°,  $[\alpha]_D^{25} + 29^\circ \rightarrow [\alpha]_D^{25} + 6.7^\circ$  in  $\text{H}_2\text{O}$  in 61 days, when boiled with  $\text{H}_2\text{O}$ , gives a mixture of  $\alpha\delta$ -(I), m.p. 187–189° (decomp.; corr.),  $[\alpha]_D^{25} - 49.1^\circ \rightarrow [\alpha]_D^{25} + 8^\circ$  in  $\text{H}_2\text{O}$  in 62 days, and  $\gamma$ -*lactone* (II),  $+\text{H}_2\text{O}$ , double m.p. about 66–70° and 133° (corr.),  $[\alpha]_D^{25} + 32.5^\circ \rightarrow [\alpha]_D^{25} + 10.6^\circ$  in  $\text{H}_2\text{O}$  in 60 days. Na-Hg reduction of (I) gives *d*-altronic acid, that of (II) *d*-talonic acid. R. S. C.

Hydrazine compounds of *d*-galacturonic acid and the isolation of crystalline *d*-galacturonic acid from tobacco. H. COLLATZ (Ber., 1936, 69, [B], 485–492; cf. Neuberg *et al.*, A., 1932, 202).—Conditions are precisely defined for the conversion of *d*-galacturonic acid (I) into its phenylhydrazone, m.p. 134° (corr.; decomp.), *p*-bromophenylhydrazone, m.p. 152–153° (corr.; decomp.), *p*-nitrophenylhydrazone, m.p. about 170–175° (decomp.) according to the rate of heating; 2 : 4-dinitrophenylhydrazone (II), m.p. 152° (corr.; decomp.), and thiosemicarbazide derivative,  $\text{C}_7\text{H}_{15}\text{O}_7\text{N}_3\text{S} \cdot \text{H}_2\text{O}$ , m.p. 147° (corr.; decomp.). Tobacco leaves are repeatedly extracted with  $\text{H}_2\text{O}$ , and the dry residue is hydrolysed with boiling 2.5%  $\text{H}_2\text{SO}_4$ . The mixture is treated with  $\text{BaCO}_3$  and filtered. The filtrate is conc. at 50°/vac. and the mixture (III) of Ba and Ca galacturonate (IV) is pptd. by EtOH. From (III) the free uronic acid is obtained by treatment with  $\text{H}_2\text{SO}_4$  in amount equiv. to Ba and from (IV) by means of  $\text{H}_2\text{C}_2\text{O}_4$ . The solutions are conc. to a syrup, which is dissolved in EtOH. Treatment of the solution with 2 : 4- $\text{C}_6\text{H}_3(\text{NO}_2)_2 \cdot \text{NH} \cdot \text{NH}_2$  affords (II), converted by MeCHO into (I),  $[\alpha]_D^{25} + 50.74^\circ$  in  $\text{H}_2\text{O}$  (equilibrium val.). H. W.

*d*-Saccharodilactone. K. REHORST and H. SCHOLZ (Ber., 1936, 69, [B], 520–526).—Potato starch (200 g.) is mixed with  $\text{H}_2\text{O}$  (200 c.c.) and  $\text{HNO}_3$  (d 1.20, 800 c.c.) and then evaporated at 100° to incipient discoloration. Treatment of the product with a slight excess of  $\text{K}_2\text{CO}_3$  followed by AcOH gives pure KH *d*-saccharate, converted through the Ca salt into *d*-saccharomonolactone. Since for further work the purity of the product is essential it is recryst. from  $\text{Et}_2\text{O}$  in a continuous extraction apparatus, thus giving a material of m.p. 133°,  $[\alpha]_D^{25} + 40.2^\circ$  in  $\text{H}_2\text{O}$ . It suffers partial hydration during titration with 0.1N-NaOH. When heated over  $\text{P}_2\text{O}_5$  at 100°/vac. it is transformed into *d*-saccharodilactone (I), m.p. 134–135° after softening at 132°,  $[\alpha]_D^{25} + 164.6^\circ$  to  $+33.5^\circ$  in  $\text{H}_2\text{O}$  in 10 days. The presence

of the  $\delta$ -lactone ring is shown by the immediate and rapid mutarotation and the immediate neutralisation of alkali in presence of phenolphthalein. The total consumption of alkali exceeds that required for the opening of the two lactone rings. Chemically (I) resembles mannosaccharodilactone, since it is resinified by alkali and reduces Fehling's solution and  $\text{Ag}_2\text{O} \cdot \text{NH}_3$ ; with I-KOH it affords  $\text{CHI}_3$ . H. W.

Attempts to reduce carbon monoxide electrocatalytically. G. FESTER and M. SCHIVAZAPPA (Rev. fac. quim. ind. agr., 1930, 1, 53–57).—The combination of catalytic and cathodic reduction of CO in solution gave determinable amounts of  $\text{CH}_2\text{O}$ , and small amounts of  $\text{HCO}_2\text{H}$  and MeOH.

Polymeride of acetaldehyde. M. LETORT (Compt. rend., 1936, 202, 767–768; cf. this vol., 316).—Pure MeCHO (prep. described) when distilled from a vessel at  $-15^\circ$  to one at  $-185^\circ$  at  $10^{-3}$  to  $10^{-5}$  mm. affords a spongy polymeride, which is slowly reconverted at room temp. into MeCHO, and reacts violently with fuming  $\text{HNO}_3$  to give  $\text{PhNO}_2$ . J. L. D.

Methylglyoxal. T. BERSIN (Ber., 1936, 69, [B], 560–562; cf. Schubert, this vol., 55).—The bimol. form of AcCHO (in  $\text{H}_2\text{O}$ ) is the hydrate  $\text{OH} \cdot \text{CHAc} \cdot \text{O} \cdot \text{CMe}(\text{OH}) \cdot \text{CH}(\text{OH})_2$  or  $\text{O} \cdot \text{CMe}(\text{OH}) \cdot \text{CH}(\text{OH}) \cdot \text{CH}(\text{OH}) \cdot \text{CMe}(\text{OH}) \cdot \text{O}$ , b.p. 25–27°/14–17 mm., 104–105°/743 mm.; in AcOH it suffers partial decomp. into AcCHO and  $\text{H}_2\text{O}$ . Reversible dissociation with production of yellow colour occurs during distillation under atm., but not under diminished pressure. Schubert's semi-mercaptal from AcCHO and  $\text{SH} \cdot \text{CHMe} \cdot \text{CO}_2\text{H}$  or glutathione is unimol. in  $\text{H}_2\text{O}$  and has the structure  $\text{OH} \cdot \text{CHAc} \cdot \text{SR}$ . The substrate of methylglyoxalase has the constitution  $\text{CO}_2\text{H} \cdot \text{CH}(\text{NH}_2) \cdot [\text{CH}_2]_2 \cdot \text{CO} \cdot \text{NH} \cdot \text{CH}(\text{CO} \cdot \text{NH} \cdot \text{CH}_2 \cdot \text{CO}_2\text{H}) \cdot \text{CH}_2 \cdot \text{S} \cdot \text{CHAc} \cdot \text{OH}$ . Under the influence of the flavin enzyme (I) gives an acid, probably  $\text{OH} \cdot \text{CHMe} \cdot \text{CO}_2\text{H}$ . H. W.

Photo-activation of the carbonyl group in prototropic reactions. W. S. NATHAN (Nature, 1936, 137, 460). L. S. T.

Acetonecyanohydrin. R. F. B. COX and R. T. STORMONT (Org. Syntheses, 1935, 15, 1–2).—An improved prep. from  $\text{COMe}_2$ , NaCN, and  $\text{H}_2\text{SO}_4$  is recorded. CH. ABS. (7)

Action of mixed organomagnesium compounds on aliphatic  $\alpha$ -ethylenic ketones. II. J. COLONGE (Bull. Soc. chim., 1936, [v], 3, 413–418; cf. A., 1935, 847).— $\text{COMe} \cdot \text{CPr}_2 \cdot \text{OH}$  is dehydrated (99.5%  $\text{H}_2\text{SO}_4$ ) to  $\text{CHEt} \cdot \text{CPr} \cdot \text{COMe}$ , b.p. 66–74°/9 mm., separated (method: Locquin and Heilmann, A., 1928, 509) into *cis*-, b.p. 72°/9 mm., and *trans*-, b.p. 71–75°/9 mm., forms, both of which with  $\text{MgEtBr}$  at 15–20° give approx. equal amounts of *Me*  $\beta$ -ethyl- $\alpha$ -propylbutyl ketone, b.p. 199–200°/747 mm. (semicarbazone, m.p. 125°), and  $\gamma$ -methyl- $\delta$ -propyl- $\Delta^2$ -hepten- $\gamma$ -ol (not obtained pure).  $\text{COMe} \cdot \text{CH}_2 \cdot \text{CHPr} \cdot \text{OH}$

is dehydrated (trace of I) to *trans*-CHPr:CH·COMe, b.p. 58—59°/13 mm., 158—159°/750 mm., whilst the *cis*-form, b.p. 61.5—63°/13 mm., is prepared (cf. Eccott and Linstead, A., 1930, 893) from PrCHO, COMe<sub>2</sub>, and 15% NaOH; both forms with MgEtBr give 40% of *Me β-ethylamyl ketone*, b.p. 72°/12 mm. (*semicarbazone*, m.p. 115°), and 60% of *γ-methyl-Δ<sup>8</sup>-octen-γ-ol*, b.p. 69—70°/10 mm. (cf. Grignard and Dubien, A., 1925, i, 111). H. B.

**Reducibility of bromo-ketones by hydrogen bromide and consequences thereof.** F. KRÖHNKE and H. T. TRIMLER (Ber., 1936, 69, [B], 614—621).—In principle, all Br-ketones and related compounds are reducible by HBr, the ease depending on their constitution. Simple Br-ketones such as CPh·CH<sub>2</sub>Br in which no activating group except CO is present require a Br acceptor. The ready reducibility of others is shown by the ease with which in EtOH or COMe<sub>2</sub> they liberate I from aq. KI. CO<sub>2</sub>H or CO<sub>2</sub>Et are feebly activating, but 2 CO<sub>2</sub>Et facilitate elimination of Br as in CHBr(CO<sub>2</sub>Et)<sub>2</sub>, which gives a marked "I reaction." CHPhBzBr, CPh·CHBr<sub>2</sub>, CBr<sub>3</sub>·CHO, and CHBr<sub>2</sub>·CO·CO<sub>2</sub>H react in order of increasing ease. The difficulty of introducing 2 Br at the same C atom is due to the counteraction of HBr. Thus the direct conversion of CPhEt into CPh·C<sub>2</sub>H<sub>5</sub>Br<sub>2</sub> appears impossible, but the *compound*, m.p. 31°, is formed if HBr is removed after formation of CPh·C<sub>2</sub>H<sub>5</sub>Br and bromination is then repeated. CHBr<sub>2</sub>·CO<sub>2</sub>H is resistant towards HBr, but CBr<sub>3</sub>·CO<sub>2</sub>H is somewhat affected. CH<sub>2</sub>Bz<sub>2</sub> + Br<sub>2</sub> ⇌ CHBz<sub>2</sub>Br + HBr is established unless HBr is removed. With CH<sub>2</sub>Ac·CO<sub>2</sub>Et the initial product is CHAcBr·CO<sub>2</sub>Et; Br removed therefrom by HBr re-enters in the *γ*-position, giving thus CH<sub>2</sub>Br·CO·CH<sub>2</sub>·CO<sub>2</sub>Et as final product. Treatment of CH<sub>2</sub>AcBz with NaOBr gives CHAcBzBr, transformed by C<sub>5</sub>H<sub>5</sub>N through a non-isolated enolbetaine into AcOH and phenacylpyridinium bromide; with HBr·AcOH the Br of CHAcBzBr wanders with production of CH<sub>2</sub>Bz·CO·CH<sub>2</sub>Br, converted by C<sub>5</sub>H<sub>5</sub>N into *benzoylacetonylpyridinium bromide*, m.p. 181° (decomp.) (corresponding *perchlorate*, m.p. 169°), which with alkali yields BzOH, AcOH, and methylpyridinium salt. Since NO<sub>2</sub> is more strongly activating than CO, Br can be readily removed from aliphatic Br·NO<sub>2</sub>-compounds such as CH<sub>2</sub>Br·NO<sub>2</sub> and NO<sub>2</sub>·CBr(CO<sub>2</sub>Et)<sub>2</sub>; N<sup>+</sup> in quaternary salts also activates if CO also is present. Determination of otherwise stable Br-ketones can be effected if a suitable acceptor, such as β-C<sub>10</sub>H<sub>7</sub>·OH, is present. The bearing of the observation on the indirect enol titration is discussed. The suggested mechanism of debromination is ·CO·CHBr· + HBr → ·(OH)CBr·CHBr· → ·(OH)C·CH· + Br<sub>2</sub> → ·CO·CH<sub>2</sub>·.

H. W.

**Reaction of sulphur and keto-alcohols in glycerol containing iron.** E. ZMACZYNSKI (Compt. rend., 1936, 202, 668—669).—Benzoin, fructose (I), or CO(CH<sub>2</sub>·OH)<sub>2</sub> heated with S in glycerol (II) containing combined Fe gives a black coloration and then a ppt.; the change does not occur in pure (II). The reaction appears to be sp. for the OH·CH·CO· group;

0.1 mg. of S in 1 c.c. of (II) is also detectable and (I) can be distinguished from glucose or sucrose.

H. B.

***d*-Psicose.** (FRL.) M. STEIGER and T. REICHSTEIN (Helv. Chim. Acta, 1936, 19, 184—189).—*d*-Ribose, HCN, and Ba(OH)<sub>2</sub> give *d*-altronic acid (Cd salt, cryst.) and *d*-allonolactone (*diisopropylidene* derivative, b.p. about 130°/1 mm.); the lactone with Na-Hg gives *d*-allose (I), m.p. 128—130° (corr.), which is isomerised by hot C<sub>5</sub>H<sub>5</sub>N to a mixture, whence is obtained a poor yield of *d*-*psicose* (II), an oil, [α]<sub>D</sub><sup>20</sup> +3.1° in H<sub>2</sub>O, stable to yeast and best isolated as *diisopropylidene* derivative, b.p. 104—105°/0.3 mm., m.p. 57—58.5°, [α]<sub>D</sub><sup>20</sup> —98.2° in COMe<sub>2</sub>. *l*-Psicose (III) gives an oily *dicyclohexylidene* derivative. Hydrogenation (Ni-kieselguhr) in EtOH at 140°/120 atm. gives *allodulcitol*, m.p. 150—151° (corr.). *d*-Allosazone, m.p. 173—174° (decomp.), [α]<sub>D</sub><sup>20</sup> —19.2° ± 4° in EtOH, variable in C<sub>5</sub>H<sub>5</sub>N, is obtained from (I) and (II), and the *l*-isomeride from (III); the *dl*-form has m.p. 204° (decomp.).

R. S. C.

**Preparation of *d*-ribose.** (FRL.) M. STEIGER (Helv. Chim. Acta, 1936, 19, 189—195).—*d*-Ribose is prepared in 17% over-all yield from arabinose by electrolytic oxidation to Ca *d*-arabonate, isomerisation by boiling C<sub>5</sub>H<sub>5</sub>N to *d*-ribonolactone, and controlled reduction of this by 2.5% Na-Hg; it is isolated as *p*-bromophenylhydrazine, m.p. 166—167°, from which it is obtained by PhCHO. R. S. C.

**Determination of *O*- and *N*-acetyl and structure of osazone acetates.** M. L. WOLFROM, M. KONIGSBERG, and S. SOLTZBERG (J. Amer. Chem. Soc., 1936, 58, 490—491).—Freudenberg and Harder's method (A., 1923, ii, 884) of determination of Ac gives *O*-+*N*-Ac, whilst Kunz and Hudson's method (A., 1926, 941) gives *O*-Ac only. It is thus possible to distinguish, e.g., *aldehydo*- and *β*-*d*-glucoseoxime hexa-acetates, since the latter contains 1 *N*-Ac. *d*-Glucose-, m.p. 115—117°, [α]<sub>D</sub><sup>25</sup> (in CHCl<sub>3</sub>) —55° → —45° (cf. Maurer and Schiedt, this vol., 193), and *d*-galactose-phenylosazone tetra-acetate, m.p. 178—179° (decomp.), [α]<sub>D</sub><sup>25</sup> +87° in CHCl<sub>3</sub> (from the osazone and Ac<sub>2</sub>O in C<sub>5</sub>H<sub>5</sub>N at room temp.), contain 4 *O*-Ac groups, indicating open-chain structures.

H. B.

**Carbohydrates. VII. Xanthate reaction of glucose.** T. LIESER and R. THIEL (Annalen, 1936, 522, 48—55).—The solution (A) from α-methylglucoside (I), 2*N*-NaOH, and CS<sub>2</sub>, with CO<sub>2</sub> followed by CuOAc, gives Cu<sub>2</sub> α-methylglucosidyl dioxanthate. (A) with AcOH (slight excess), followed by CO<sub>2</sub> and Cd(OAc)<sub>2</sub>, yields the Cd dioxanthate (II); with CO<sub>2</sub> and 0.1*N*-I the (impure) dioxanthogen, C<sub>9</sub>H<sub>12</sub>O<sub>6</sub>S<sub>4</sub>, is obtained. β-Phenylglucoside (III) similarly leads to Cd β-phenylglucosidyl dioxanthate and a polyxanthogen (shown by fractionation to be mainly di- with small amounts of mono-, tri-, and tetra-xanthogens). A small amount of dioxanthate is also obtained (cf. A., 1935, 1354) from (I), 0.36*N*-Ba(OH)<sub>2</sub>, and CS<sub>2</sub>; the purified solution (B) and Cd(OAc)<sub>2</sub> give a little (II). (B) with MeI or Me<sub>2</sub>SO<sub>4</sub> affords the H<sub>2</sub>O-sol. Me α-methylglucosidyl xanthate (*loc. cit.*) and a little of the non-cryst., H<sub>2</sub>O-insol. Me<sub>2</sub> α-

*methylglucosidyl dioxanthate* [also obtained from the previously described (*loc. cit.*) Ag salt and MeI]. Ba  $\beta$ -phenylglucosidyl xanthate (*loc. cit.*) with  $\text{CH}_2\text{Cl}\cdot\text{CO}\cdot\text{NEt}_2$  and MeI gives 52.6% of  $\text{NEt}_2\cdot\text{CO}\cdot\text{CH}_2$ , m.p. 133—135° (corr.), and 66% of Me, m.p. 173—174°,  $\beta$ -phenylglucosidyl xanthate, respectively. (III) with 3.5N- $\text{NEt}_2\cdot\text{OH}$  and  $\text{CS}_2$ , followed by MeI (or  $\text{Me}_2\text{SO}_4$ ) or I (slight excess), yields  $\text{Me}_4$   $\beta$ -phenylglucosidyl tetraaxanthate (26%), m.p. 135° (corr.) or the *trixanthogen*, respectively. Homogeneous cryst. di- and tri-xanthates could not be prepared from glucose. H. B.

**Position of the equilibrium and specificity of the  $\beta$ -glucosidase action.** C. N. IONESCU (Ber., 1936, 69, [B], 588—591).—Further evidence (cf. A., 1934, 927) is adduced in favour of the view that the law of mass action is unreservedly applicable to reactions catalysed by  $\beta$ -glucosidase if the concn. of  $\beta$ -glucose instead of total glucose is considered. The apparent deviations caused by increasing  $[\text{EtOH}]$  are not due to inactivation of the enzyme but to displacement of the equilibrium  $\beta \rightleftharpoons \alpha$ -glucose towards the  $\alpha$ -form. H. W.

**Kinetics of  $\beta$ -glucosidase action.** C. N. IONESCU and A. KIZYK (Ber., 1936, 69, [B], 592—597).—The experiments of Bourquelot and present experiments with  $\beta$ -methyl- (I) and  $\beta$ -ethoxyethylglucoside show no deviation from the law of mass action. If, separately, the hydrolysis of a definite amount of (I) and parallel to it the syntheses of the same glucoside are effected whereby equiv. amounts of glucose and (I) are involved, it is possible to calculate four velocity coeffs. The hydrolysis experiment gives a velocity coeff. for the hydrolysis  $k_2$  and for the synthesis  $k_1$  by reason of the reversible process. Analogously from the synthetic experiment velocity coeffs. for the synthesis  $k_1$  and for the opposed hydrolysis  $k_2$  are derived. The ratio of any velocity coeff. of hydrolysis to any velocity coeff. of synthesis is the same and is identical with the equilibrium const. from the concns. at the completion of the reaction. von Euler's hypothesis is not applicable to the synthesis of  $\beta$ -glucosides even in those cases in which the affinity of the glucoside for  $\beta$ -glucosidase may be assumed to differ appreciably from that of glucose. H. W.

**Photochemical reactions of *o*-nitrobenzylidenacetals.** IX. *o*-Nitrobenzylidenacetals of the oses. I. TANASESCU and E. CRACIUNESCU (Bull. Soc. chim., 1936, [v], 3, 581—598; cf. A., 1933, 275, 393; 1934, 169).—Treatment of galactose with  $\text{o-NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CHO}$  in presence of  $\text{P}_2\text{O}_5$  or, preferably, anhyd.  $\text{Na}_2\text{SO}_4$  at 40—45° for 5—6 hr. gives 1:2(? 1:3)-4:6-*di-o-nitrobenzylidenegalactose* (I), m.p. 135° after softening,  $[\alpha] \pm 0^\circ$  in  $\text{CHCl}_3$  or  $\text{C}_5\text{H}_5\text{N}$ . It is very resistant to acid hydrolysis, which, however, can be effected by  $\text{HNO}_3$  (1:1). It does not react with  $\text{AcCl}$  or  $\text{BzCl}$  in  $\text{C}_5\text{H}_5\text{N}$  or in presence of alkali, and is indifferent towards  $\text{PhSO}_2\text{Cl}$  or  $p\text{-C}_6\text{H}_4\text{Me}\cdot\text{SO}_2\text{Cl}$ . It does not give a phenylhydrazone or reduce  $\text{Ag}_2\text{O}\cdot\text{NH}_3$ . Reduction of (I) with Zn dust in boiling  $\text{COMe}_2$  containing  $\text{CaCl}_2$  gives a very unstable basic substance, m.p. 118°. Insolation of (I) in  $\text{CHCl}_3$  affords 1:2(? 1:3)-*o-nitrobenzylidenegalactose* 4-*o*-

*nitrosobenzoate*, m.p. 147° after shrinking,  $[\alpha] \pm 0^\circ$  in  $\text{C}_5\text{H}_5\text{N}$ , the constitution of which is deduced from the isolation of the corresponding 6-*benzoate*, m.p. 165° (decomp.) after softening, 6-*acetate*, m.p. about 135° after softening, and 6-*benzenesulphonate*, m.p. 162° after softening, and its condensation with 1 mol. of  $\text{NH}_2\text{Ph}$  in glacial  $\text{AcOH}$  to 1:2(? 1:3)-*o-nitrobenzylidenegalactose* 4-*o-phenylazobenzoate*, m.p. 154° after shrinking. 1:2(? 1:3)-4:6-*Di-m-nitrobenzylidenegalactose*, m.p. 122° after softening, is obtained similarly but in poorer yield, and is similarly reduced to an unstable base.  $\alpha$ -Methylgalactoside and  $\text{o-NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CHO}$  in presence of  $\text{P}_2\text{O}_5$  (but not of anhyd.  $\text{Na}_2\text{SO}_4$ ) at 45° afford 2:3-4:6-*di-o-nitrobenzylidene- $\alpha$ -methylgalactoside*, m.p. 105° after softening, rapidly isomerised by insolation in  $\text{CHCl}_3$  to the substance  $\text{C}_{21}\text{H}_{20}\text{O}_{10}\text{N}_2$ , m.p. 155° after softening. 1:2(? 1:3)-4:6-*Di-o-nitrobenzylidenemannose*, m.p. 120° after softening, readily obtained at  $\geq 50^\circ$ , is hydrolysed by  $\text{HNO}_3$  (1:1), cannot be acylated, and does not give a phenylhydrazone; insolation of it affords 1:2(? 1:3)-*o-nitrobenzylidenemannose* 4-*o-nitrosobenzoate*, m.p. 145° after softening,  $[\alpha] \pm 0^\circ$ , which yields a 4-*benzoate*, m.p. 165° after softening, and 4-*benzenesulphonate*, m.p. 160° after softening, and is transformed by  $\text{NH}_2\text{Ph}$  into 1:2(? 1:3)-*o-nitrobenzylidenemannose* 4-*o-phenylazobenzoate*, m.p. 154° after softening. 1:2(? 1:3)-*Di-m-nitrobenzylidenemannose*, m.p. 110° after softening, is reduced to a very unstable base. In presence of  $\text{P}_2\text{O}_5$  at 40°, rhamnose is rapidly condensed to 1:2-3:4-*di-o-nitrobenzylidenerrhamnose*, m.p. about 105° (decomp.), which cannot be acylated and is isomerised to the compound  $\text{C}_{20}\text{H}_{19}\text{O}_9\text{N}_2\cdot\text{H}_2\text{O}$ , m.p. about 150° after softening, 2:3-4:6-*Di-o-nitrobenzylidenefructose*, m.p. 112° after softening,  $[\alpha] \pm 0^\circ$  in  $\text{C}_5\text{H}_5\text{N}$ , gives a phenylhydrazone, m.p. 126°, after softening. Lactose in presence of  $\text{P}_2\text{O}_5$  and  $\text{Na}_2\text{SO}_4$  at 70° slowly affords *tri-o-nitrobenzylidenelactose*, m.p. about 220° after softening, isomerised by light to the compound  $\text{C}_{33}\text{H}_{31}\text{O}_{17}\text{N}_3$ , m.p.  $> 300^\circ$ . Sucrose more readily yields *di-o-nitrobenzylidenesucrose*, m.p. 135° after softening, converted by insolation into the substance  $\text{C}_{26}\text{H}_{28}\text{O}_{13}\text{N}_2$ , m.p. 185° after softening. H. W.

**Hyperacetylation of aldoses.** N. W. PIRIE (Biochem. J., 1936, 30, 374—376).—The *hepta-acetates* of *d*-galactose, m.p. 106°,  $[\alpha]_D + 4.0^\circ$ , *d*-mannose, m.p. 122°,  $[\alpha]_D + 0.4^\circ$ , *d*-glucose, m.p. 121—122°,  $[\alpha]_D^{20} + 7.9^\circ$ , and the *hexa-acetates* of *l*-arabinose, m.p. 91°,  $[\alpha]_D^{20} - 27.7^\circ$  (all in  $\text{CHCl}_3$ ), *l*-rhamnose, m.p. 72—73°,  $[\alpha]_D^{20} - 7.5^\circ$  in  $\text{MeOH}$ , and *d*-xylose,  $[\alpha]_D^{17} + 4.0^\circ$  in  $\text{CHCl}_3$ , were prepared from the appropriate aldose penta- and tetra-acetate  $\text{Et}_2$  mercaptals. *d*-Mannose penta-acetate, m.p. 51—52°,  $[\alpha]_D^{17} + 31.2^\circ$  in  $\text{CHCl}_3$ , and *l*-rhamnose tetra-acetate  $\text{Et}_2$  mercaptal, m.p. 60°,  $[\alpha]_D^{15} + 39.5^\circ$  in  $\text{CHCl}_3$ , are described. H. D.

**Preparation of *dl*-galactose hepta-acetate by the acetolysis of agar.** N. W. PIRIE (Biochem. J., 1936, 30, 369—373).—*dl*-Galactose hepta-acetate (I) is prepared by treatment of agar with  $\text{Ac}_2\text{O}$  and  $\text{H}_2\text{SO}_4$ . After slight hydrolysis of agar with 0.1N- $\text{H}_2\text{SO}_4$  for 40 min.,  $\text{Ac}_2\text{O}$  gave the usual yield of (I); completely hydrolysed agar gave no (I) but *dl*- and *d*-galactose penta-acetate were isolated. H. D.

**Oxidation of mannose to mannonic acid by *B. gluconicum*.**—See this vol., 640.

(A) Delay and "prolongation" of reaction during the decomposition of fructose in ultra-violet light. Light-induced [light-activated] fructose. (B) Effect of sodium chloride and other metal halides on [the decomposition of] fructose in ultra-violet light. R. CANTIENI (Helv. Chim. Acta, 1936, 19, 270—276, 276—280).—(A) 10% aq. fructose solution decomposes in ultra-violet light to give CO with a little CO<sub>2</sub> and (in light of short  $\lambda$ ) H<sub>2</sub> (cf. A., 1932, 237). Reaction commences only after irradiation for about 45 min., then increases to a fixed val. ("delay of reaction"), and continues at a decreasing rate for many hr. after irradiation has ceased ("prolongation of reaction"). The vol. of gas liberated after cessation of irradiation about equals the decrement due to the delay of the reaction. It is assumed that a "light-induced" (light-activated) fructose mol. is formed by absorption of a light quantum, that this mol. has a moderate stability, and decomposes at a rate  $\propto$  its concn. partly into ordinary fructose and partly into CO and C<sub>5</sub>H<sub>12</sub>O<sub>5</sub>. In accordance with this view, (a) the activated mol. is less stable at 100° than at room temp. (since the "prolongation" is very slight at 100°), and (b) light of short  $\lambda$  gives a less stable activated mol. (less "prolongation") than does light of long  $\lambda$ . Increase of pressure increases both the delay and prolongation of the reaction, indicating increased stability of the activated mol.

(B) Addition of 25% of NaCl to a 10% fructose solution irradiated by ultra-violet light of long  $\lambda$  decreases the delay and prolongation of the reaction, without affecting the total vol. of gas liberated. The stability of the activated mol. is reduced by about 50%; the time required to give sufficient CO to be detected by hæmoglobin is reduced from 255 to 97.5 sec. KBr and, more so, KI reduce the total vol. of gas liberated, presumably by favouring decomp. of the activated mol. to ordinary fructose. R. S. C.

**Velocities of hydrolysis of glucosides.**—See this vol., 572.

**Digitalis glucosides. VI. Existence of two anhydrodigoxigenins.** S. SMITH (J.C.S., 1936, 354—355; cf. A., 1935, 1355).—Digoxigenin and conc. HCl at 10—0° give an unstable Cl-compound, m.p. 185° after decomp. at 120°, converted by hot aq. MeOH into  $\alpha$ -anhydrodigoxigenin, m.p. 192°,  $[\alpha]_{D}^{20} +46^\circ$  in MeOH (diacetate, m.p. 155°,  $[\alpha]_{D}^{20} +68^\circ$  in MeOH), oxidised by CrO<sub>3</sub> to  $\alpha$ -anhydrodigoxigenone, m.p. 178°,  $[\alpha]_{D}^{20} +136^\circ$  in MeOH [semicarbazone, m.p. 235° (decomp.); dioxime, an oil], and a substance, m.p. 215°. The similarity of this anhydro-compound and its known isomeride (now called  $\beta$ -), m.p. 182°,  $[\alpha]_{D}^{20} -16.3^\circ$ , to  $\alpha$ - and  $\beta$ - ( $[\alpha]_{D}^{20} -17.3^\circ$ ) -anhydrodigitoxigenin, respectively, is noted. R. S. C.

**Determination of particle size of polysaccharides by osmotic pressure measurements.** S. R. CARTER and B. R. RECORD (Chem. and Ind., 1936, 218—219).—Preliminary results obtained with methylated and acetylated inulin or glycogen, and methylated starch or dextrin, point to the association of the chemical units of the polysaccharide mols. into larger

aggregates and confirm the structural views of Haworth and collaborators. E. S. H.

**Colloid-chemical aspects of starch.** J. ALEXANDER (Chem. and Ind., 1936, 206—209).—Starch from maize, potato, tapioca, wheat, or rice swells and ultimately disperses in cold, conc. HCO<sub>2</sub>H. The optical properties and behaviour on dilution with H<sub>2</sub>O of such solutions are described. The rôle of colloidal protection in the behaviour of starches is discussed. E. S. H.

**Hydrolysis of starch by hydrogen peroxide and ferrous sulphate.** W. R. BROWN (J. Biol. Chem., 1936, 113, 417—425; cf. Omori, A., 1932, 346).—The reaction is one of hydrolysis and appears to be a true catalysis, producing dextrans, sugars of high mol. wt., and simple sugars. It is analogous to that of amylase except that the simple sugars are further hydrolysed and oxidised to aldehydes and acids. It is assumed that the Fe transfers energy from the H<sub>2</sub>O<sub>2</sub> breakdown to the starch, causing it to be reactive. J. N. A.

**Starch nitrate.** G. CENTOLA (Gazzetta, 1936, 66, 8—15).—Rice starch with HNO<sub>3</sub> of varying concn. yields nitrates with 8.5—12.4% N. The last, the trinitrate, gives an X-ray spectrogram corresponding with a lattice distance of 7.15 Å., and similar to that given by collodion cotton of 12% N; it thus has the same structure as unstable cellulose trinitrate. Products of lower N content give diffraction lines in the same position, but wider and less distinct; the trinitrate is mixed with unchanged starch. Reaction is much more rapid than that of cellulose, owing to ease of penetration of starch grains. HNO<sub>3</sub>—H<sub>2</sub>SO<sub>4</sub>—H<sub>2</sub>O mixtures containing H<sub>2</sub>O > 20% or H<sub>2</sub>SO<sub>4</sub> > 73% give very poor yields, owing to hydrolysis and oxidation. The product obtained when H<sub>2</sub>SO<sub>4</sub> is present can be fractionated into amylose nitrate, sol. in MeOH, and amylopectin nitrate, insol.; these are hydrolysed to amylose and to amylopectin. Differences in X-ray spectra of starches of groups A, B, and C (A., 1933, 464) disappear when the latter are converted into nitrates, which thus have the same structure. E. W. W.

**Behaviour of cellulose in solutions of mineral acids. I. Determination of its mol. wt. in phosphoric acid solution. II. Kinetics of the degradation of cellulose in acid solutions.** A. AF EKENSTAM (Ber., 1936, 69, [B], 549—552, 553—559).—I. The process of dissolution of cellulose (I) in acids involves swelling. The initial process consists in the formation of oxonium compounds such as (C<sub>6</sub>H<sub>10</sub>O<sub>5</sub>, 2H<sub>2</sub>O, H<sub>3</sub>PO<sub>4</sub>)<sub>n</sub>, (C<sub>6</sub>H<sub>10</sub>O<sub>5</sub>, 4H<sub>2</sub>O, H<sub>2</sub>SO<sub>4</sub>)<sub>n</sub>, and (C<sub>6</sub>H<sub>10</sub>O<sub>5</sub>, H<sub>2</sub>O, HNO<sub>3</sub>)<sub>n</sub>. These compounds, if obtained from hemicolloidal (I), are sol. in very dil. acid, but if derived from highly polymerised (I) require acid of increasing concn. as the mol. wt. increases. At low temp. they are dissolved by a more dil. acid than at a higher temp. From the clear solutions ppts. in more or less swollen form are obtained by addition of H<sub>2</sub>O or dil. acid (provided the material is moderately complex), and these yield (I) free from acid if sufficiently washed with H<sub>2</sub>O. Except with HNO<sub>3</sub> esterification does not take place. H<sub>3</sub>PO<sub>4</sub> is preferable to H<sub>2</sub>SO<sub>4</sub> as solvent for (I), since it is less degrading;

the solutions can be kept unchanged for several hr., particularly at low temp., and are not sensitive to air, so that, in this respect,  $H_3PO_4$  is preferable to Schweitzer's reagent as solvent. Viscosimetric determinations of the mol. wt. of (I) in  $H_3PO_4$  are recorded. The highest val. (157,000) is observed for Swedish filter-paper, which contains very little native (I). The vals. for native (I) such as cotton are very uncertain and are greater in  $H_3PO_4$  than in Schweitzer's reagent. Pure hydrocellulose (II) gives concordant results in each solvent.

II. Correlation of viscosity with age of the solution shows that (II) in  $H_3PO_4$  is degraded initially at a const. rate which alters when the mol. wt. has declined to a few thousand. Native (I) is very rapidly degraded shortly after its dissolution, but the rate soon declines and gradually approaches that of (II). The relationships in  $H_2SO_4$  are similar but the initial rates are not so obvious as with  $H_3PO_4$ . A const. initial rate of degradation of (II) is not observed, the val. declining steadily. With native (I) the initial rate is somewhat  $>$  with (II), but the rates for (I) and (II) gradually become identical. It appears therefore that (II) of high mol. wt. contains a single type of linking affected by acid, whereas native (I) usually contains much larger mols. than (II) and has, in addition to the ordinary glucosidic linking, a type of union much more rapidly hydrolysed by acid.

H. W.

**Constitution of cellulose xanthates.** IV. T. LIESER and E. LECKZYCK (Annalen, 1936, 522, 56—65).—Cellulose (I) undergoes pronounced swelling in 2*N*. but dissolves in 2·27—4*N*- $NEt_4$ ·OH. (I) swells in 2*N*-, dissolves in 2·1—3·6*N*-, and is insol. in 3·8*N*-*p*-tolyltrimethylammonium hydroxide (II); the corresponding *N* for  $NEtBu_3$ ·OH are 1·5, 1·7—2·4, and 2·6. The min. concn. for complete solubility thus decreases with increased mol. wt. of the base. (I) reacts rapidly with  $CS_2$  in 3·7*N*- $NEt_4$ ·OH at 0° to give  $(NEt_4)_3$  cellulose trixanthate (III), which is oxidised by 0·1*N*-I in MeOH to the nearly pure trixanthogen,  $[C_6H_7O_5(CS_2)_3]_2$ . (III) is sol. in MeOH (pptd. by  $Et_2O$ ) or  $COMe_2$ , but is insol. in EtOH. When solutions of (III) in  $H_2O$  or MeOH are kept for 3 days at room temp. and then oxidised by I, the xanthogen formed contains 18—20% S; the "ripening" is much slower in MeOH at 0°. The dixanthogen,  $[C_6H_8O_5(CS_2)_2]_2$ , is the main product from (I),  $CS_2$ , and 2·5*N*- $NPr_4$ ·OH, 2·35*N*- $NEtBu_3$ ·OH, or 3·6*N*-(II), followed by oxidation. (I) is insol. in CsOH (all concns.).

H. B.

**Degradation of simple amines during "kjeldahlisation."** E. KAHANE and J. G. CARRERO (Bull. Soc. chim., 1936, [v], 3, 397—408).— $NH_2Me$  is produced rapidly from  $NHMe_2$ , and slowly from  $NMe_3$ , during the action of boiling conc.  $H_2SO_4$ ; slow conversion into  $NH_3$  then occurs. The analogous changes with  $NHEt_2$  and  $NEt_3$  take place more readily. Catalysts, in increasing order of efficiency, are  $K_2SO_4 + CuSO_4$  (A),  $HClO_4$ ,  $SeO_2$ ;  $NH_2Et$  is thus completely converted into  $NH_3$ .  $NH_3$  is formed to the extent of 87—97% during "kjeldahlisation" [catalyst (A)] of  $(CH_2)_6N_4$ ,  $NHPhMe$ ,  $NPhMe_2$ , and novocaine; ephedrine, adrenaline, and hordenine

similarly give (mainly)  $NH_3 + NH_2Me$ , whilst betaine affords  $NH_2Me + NHMe_2$ . The amine mixtures are determined by Weber and Wilson's method (A., 1918, ii, 377).

H. B.

**Decomposition of ethylamine and diethylhydrazine.**—See this vol., 568.

**Action of ammonia on esters.** F. D. CHATTAWAY (J.C.S., 1936, 355—358).—The normal action of  $NH_3$ ,  $NH_2R$ , or  $NH_2\cdot NHR$  on esters,  $R'\cdot CO_2R''$  ( $\rightarrow R'\cdot OH + R'\cdot CO\cdot NH_2$  etc.), is due to the cationoid nature of the C of the  $CO$ . If, however, the alkyl carries a sufficiently powerful cationoid centre, the N will become attached to  $R''$ , yielding  $R'\cdot CO_2H$  and  $NH_2R''$  etc., as in the following cases. With the appropriate basic reagents under the usual conditions  $CCl_3\cdot CH(CH_2\cdot NO_2)\cdot OAc$  yields  $\gamma\gamma$ -trichloro- $\alpha$ -nitro- $\beta$ -aminopropane, b.p.  $108^\circ/2$  mm. (hydrochloride, cryst.; Ac derivative, m.p.  $137^\circ$ ), and the corresponding  $\beta$ -*p*-toluidino-, m.p.  $61^\circ$ ,  $\beta$ -phenyl-, m.p. about  $120^\circ$  (decomp.) [ $Ac_2$  derivative, m.p.  $199$ — $200^\circ$  (decomp.)],  $\beta$ -*p*-tolyl-, m.p.  $115^\circ$  ( $Ac_2$  derivative, m.p.  $157$ — $158^\circ$ ),  $\beta$ -chlorophenyl-, m.p.  $118^\circ$  ( $Ac_2$  derivative, m.p.  $152^\circ$ ), 2:4-dichlorophenyl-, m.p.  $79^\circ$  ( $Ac_2$  derivative, m.p.  $125^\circ$ ), and  $\beta$ -*m*-nitrophenyl-hydrazino-compounds, m.p.  $112$ — $113^\circ$ .  $CHMeCl\cdot CCl_2\cdot CH(CH_2\cdot NO_2)\cdot OAc$  gives similarly  $\gamma\gamma\delta$ -trichloro- $\alpha$ -nitro- $\beta$ -amino-, m.p.  $54$ — $55^\circ$  (hydrochloride, cryst.; Ac derivative, m.p.  $104^\circ$ ),  $\beta$ -*p*-toluidino-, m.p.  $110^\circ$ , and  $\beta$ -phenylhydrazino-pentane, m.p.  $129^\circ$  (Ac, m.p.  $111^\circ$ , and  $Ac_2$  derivative, m.p.  $158$ — $159^\circ$ ).

R. S. C.

**Reaction of tris- $\beta$ -hydroxyethylamine with tungstic acid.**—See this vol., 575.

**Oxidation of amino-acids by hypochlorite.** I. Glycine. M. F. NORMAN (Biochem. J., 1936, 30, 484—496).—For complete oxidation of glycine (I) by  $NaOCl$ , 1 mg. of (I) requires 4·26 mg. of Cl, the observed increase in Cl' being equiv. to one half of the Cl used. The reaction is complete in 2 hr. between concns. of 0·05 millimol. per 100 ml. of acid or alkali, but is retarded at a higher concn. During the reaction the  $p_H$  falls, oxidation being most rapid between  $p_H$  7 and 9. In the first stage  $HCN$ ,  $CO_2$ , and  $H_2O$  are formed;  $HCN$  then gives  $HCO_2H$  and  $NH_3$  and finally  $CO_2$ ,  $H_2O$ , and  $N_2$ , thus accounting for  $4\frac{1}{2}$  atoms of O per mol. of (I).

H. G. R.

**Effect of heat on betaine.** H. T. STRAW and H. T. CRANFIELD (J.S.C.I., 1936, 55, 40—41t).—Betaine as the free base was prepared by neutralising betaine hydrochloride dissolved in MeOH with 25%  $NaOH$ -MeOH, pptd.  $NaCl$  being removed by filtration. On heating the recryst. and dried betaine in a current of air no decomp. occurred below  $200^\circ$ , but at  $260^\circ$  a pale yellow oil began to distil over, the rate of evolution increasing up to  $295^\circ$  and decomp. being complete at  $300^\circ$ . The products isolated were  $NMe_2\cdot CH_2\cdot CO_2Me$  (max. yield 30%),  $NMe_3$ ,  $NHMe_2$ ,  $NH_2Me$ ,  $N_2$ ,  $CH_3O$ , pyrrole, and a carbonaceous residue containing N. The distribution of N in the main decomp. products was 7·2% as  $NHMe_2$ , 29·7% as  $NMe_3$ , 19·9% as  $N_2$ , 32·6% as oil, and 10·6% as residues.

**Stepwise degradation of polypeptides.** M. BERGMANN, L. ZERVAS, and (in part) F. SCHNEIDER

(J. Biol. Chem., 1936, 113, 341—357; cf. A., 1934, 802).—Stepwise degradation of polypeptides is effected thus:  $\text{NH}_2\cdot\text{CHR}\cdot\text{CO}_2\text{H} \rightarrow \text{NHBz}\cdot\text{CHR}\cdot\text{CO}_2\text{H} \rightarrow \text{CON}_3\cdot\text{CH}_2\text{Ph}\cdot\text{OH} \rightarrow \text{NHBz}\cdot\text{CHR}\cdot\text{NH}\cdot\text{CO}\cdot\text{O}\cdot\text{CH}_2\text{Ph} + \text{H}_2 \xrightarrow{\text{Pd}} \text{NHBz}\cdot\text{CHR}\cdot\text{NH}_2 + \text{H}_2\text{O} \rightarrow \text{R}\cdot\text{CHO}$  (characterised). Thus *N*-benzoyl-*l*-leucine *Me* ester, m.p. 104° (from *l*-leucine-HCl-MeOH-BzCl), with  $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$ -EtOH gives the *hydrazide*, m.p. 153°, converted by  $\text{NaNO}_2\cdot 5\text{N}\cdot\text{HCl}$ -50% AcOH at 0°, and  $\text{CH}_2\text{Ph}\cdot\text{OH}$  into  $\alpha$ -benzamido- $\alpha$ -carbobenzyloxyamido-, m.p. 178°, reduced ( $\text{H}_2$ -Pd-5N-HCl) to  $\alpha$ -amino- $\alpha$ -benzamido- $\gamma$ -methyl-*n*-butane hydrochloride,  $[\alpha]_D^{25} -47^\circ$  in MeOH [converted by boiling MeOH into a (*NHBz*)<sub>2</sub> derivative, m.p. 210°, of  $\text{Bu}^t\text{CHO}$ ], converted by distillation with  $\text{H}_2\text{O}$  into  $\text{Bu}^t\text{CHO}$ , isolated as its *p*-nitrophenyllhydrazone. Similar degradation of benzyl-dl-phenylalanine *Me* ester, m.p. 90°, affords, successively, its *hydrazide*, m.p. 192°,  $\alpha$ -benzamido- $\alpha$ -carbobenzyloxyamido-, m.p. 196°, and  $\alpha$ -amino- $\alpha$ -benzamido- $\beta$ -phenylethane, m.p. 156°, previous sintering (converted by  $\text{HNO}_2$  into a substance, m.p. 128°), the hydrochloride of which gives  $\text{NH}_2\text{Bz}$  and  $\text{CH}_3\text{Ph}\cdot\text{CHO}$  (as oxime). Similarly *Me* benzoyl-*l*-glutamate, m.p. 83°, gives its dihydrazide, m.p. 216°, diazide, decomp. 75°,  $\alpha$ -benzamido- $\alpha$ - $\gamma$ -biscarbobenzyloxyamidopropane, m.p. 174°, hydrogenated to the dihydrochloride, m.p. 158°,  $[\alpha]_D^{25} -50\cdot7^\circ$  in  $\text{H}_2\text{O}$  (dipicrate, + $\text{H}_2\text{O}$ , decomp. 100°), hydrolysed to  $\text{NH}_2\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{CHO}$  (I) (dimedon compound, m.p. 208—209°). The Et ester of *l*-alanine and  $\text{CH}_2\text{Ph}\cdot\text{O}\cdot\text{CO}\cdot\text{NH}\cdot\text{CH}_2\cdot\text{COCl}$  with 10%  $\text{Na}_2\text{CO}_3$  in EtOAc gives the Et ester, m.p. 59°, of carbobenzyloxyglycyl-*l*-alanine, converted into the *hydrazide*, m.p. 133°, and the *azide*, which with *l*-leucine *Me* ester gives the *Me* ester, m.p. 112°, of carbobenzyloxyglycyl-*l*-alanyl-*l*-leucine, converted through the *hydrazide*, m.p. 186°, into *Me* carbobenzyloxyglycyl-*l*-alanyl-*l*-leucyl-*l*-glutamate, m.p. 149°, hydrolysed to glycyl-*l*-alanyl-*l*-leucyl-*l*-glutamic acid + $1\cdot5\text{H}_2\text{O}$  {Bz derivative, m.p. 215° [*Me*<sub>2</sub> ester (II), m.p. 178°]}. Degradation of (II) is effected through its dihydrazide, m.p. 253°, diazide, the dicarbobenzyloxy-derivative, m.p. 201°, hydrogenated to (I) and benzoylglycyl-*l*-alanyl-*l*-leucylamide, m.p. 186°, the *hydrazide*, m.p. 230°, of which similarly affords the benzoylglycyl-*l*-alanyl derivative, m.p. 212°, of  $\alpha$ -amino- $\alpha$ -carbobenzyloxyamido- $\gamma$ -methylbutane, hydrogenated to  $\text{Bu}^t\text{CHO}$  and benzoylglycyl-*l*-alanyl-*l*-leucylamide, m.p. 192°, the *hydrazide*, m.p. 212°, of which is degraded to the benzoylglycyl derivative, m.p. 207°, of  $\alpha$ -amino- $\alpha$ -carbobenzyloxyamidoethane, hydrogenated to MeCHO and hippuramide.

J. W. B.

**Occurrence of prolinase.** E. ABDERHALDEN and R. MERKEL (Fermentforsch., 1936, 15, 1—23; cf. A., 1933, 615).—Attempts have been made to isolate the enzyme following observations of the effects of enzyme complexes on prolyl peptides. Of the peptides tested only those containing tyrosyl directly united to  $\text{CO}_2\text{H}$  are hydrolysed by trypsin (I). (I) attacks glycyl-*l*-prolyl-*l*-phenylalanine (II) slightly, *l*-leucyl-*l*-prolyl-*l*-tyrosine (III) strongly, and dl-alanyl-*l*-prolyl-*l*-phenylalanine (IV), *l*-prolylglycine (V), *l*-prolyl-*l*-alanine (VI), *l*-prolyl-*l*-serine (VII), dl-leucyl-*l*-prolylglycine (VIII), and dl-leucyl-*l*-prolyl-*l*-alanine (IX) not at all. (I) [but not erepsin (X)] hydrolyses

chloroacetyl-*l*-prolyl-*l*-phenylalanine, dl- $\alpha$ -bromopropionyl-*l*-prolyl-*l*-phenylalanine, and dl- $\alpha$ -bromoisohexoyl-*l*-prolyl-*l*-alanine. (X) attacked all the prolyl di- and tri-peptides.  $\text{H}_2\text{S}$  inactivated prolinase (XI) and dipeptidase (XII) and diminished the activity of aminopolypeptidase (XIII). Ag<sup>+</sup> and HCN diminished, in different degrees, the activity of (XI), (XII), and (XIII). The activity of (XI) and (XIII) is greatly and that of (XII) is slightly diminished by shaking (15—35 hr.). (XI) could not be isolated from solutions containing also (XII) and (XIII) by adsorption on Fe oxide and  $\text{Al}_2\text{O}_3$  but partial separation was effected. *l*-Prolyl-*l*-tyrosine (XIV) has m.p. 228°,  $[\alpha]_D^{20} -7\cdot56^\circ$ . *l*-Prolyl-*l*-phenylalanine (XV) is obtained from the product of interaction of *N*-carbobenzyloxy-*l*-proline (XVI) and  $\text{PCl}_5$  by treatment with *l*-phenylalanine Et ester and subsequent hydrolysis. The *N*-carbobenzyloxy-*l*-prolyl-*l*-phenylalanine produced gives (XV) with Pd- $\text{H}_2$ . The product of interaction of *l*-serine and (XVI) chloride gives, with Pd- $\text{H}_2$ , (VII), m.p. 215—216°,  $[\alpha]_D^{20} -47\cdot9^\circ$  in  $\text{H}_2\text{O}$ . *N*-Carbobenzyloxy- (V) has m.p. 127°. Alanine with (XVI) chloride gives *N*-carbobenzyloxy-*l*-prolyl-*l*-alanine, m.p. 153°, which, with Pd- $\text{H}_2$  yields (VI), m.p. 232°,  $[\alpha]_D^{20} -66\cdot33^\circ$  in  $\text{H}_2\text{O}$ . (XV) with AcCl gives the chloroacetyl derivative, m.p. about 78°, which yields (II), m.p. 200—202°, on amination and with dl- $\alpha$ -bromopropionyl chloride it gives  $\alpha$ -bromopropionylprolylphenylalanine, m.p. 153—154°, which with  $\text{NH}_3$  gives (IV), m.p. 176°,  $[\alpha]_D^{20} -58\cdot3^\circ$  in  $\text{H}_2\text{O}$ . (XIV) with d- $\alpha$ -bromoisohexoyl chloride gives  $\alpha$ -bromoisohexoylprolyltyrosine, m.p. about 108°, which with  $\text{NH}_3$  yields (III), m.p. about 222°,  $[\alpha]_D^{25} -7\cdot46^\circ$  in  $\text{H}_2\text{O}$ . In the same way (V) gives dl- $\alpha$ -bromoisohexoylprolylglycine, m.p. 89—91°, which yields (VIII), m.p. 224°,  $[\alpha]_D^{24} -9\cdot71^\circ$  in  $\text{H}_2\text{O}$ , and (VI) gives  $\alpha$ -bromoisohexoylprolylalanine, m.p. 107—109°,  $[\alpha]_D^{25} -67^\circ$  in EtOH, which yields (IX), m.p. 221°,  $[\alpha]_D^{25} -37\cdot36^\circ$  in  $\text{H}_2\text{O}$ . W. McC.

#### Oxidation of cystine in non-aqueous media.

**V. Isolation of a disulphoxide of *l*-cystine.** G. T. TOENNIES and T. F. LAVINE. **VI. Reactions of the disulphoxide of *l*-cystine, especially its dismutative decompositions.** T. F. LAVINE (J. Biol. Chem., 1936, 113, 571—582, 582—597).—V. Two improved techniques for the oxidation of *l*-cystine perchlorate by  $\text{BzO}_2\text{H}$  in MeCN (A., 1934, 284) to give a 75% yield of *l*-cystine disulphoxide (I), m.p. 179—182° (decomp.) (corr.),  $[\alpha]_D^{25} -30\cdot2^\circ$  in *N*-HCl, isolated by virtue of its slight  $\text{H}_2\text{O}$ -solubility, obtained cryst. by dilution of its saturated solution in *N*-HCl, are described. Rise of temp. from  $-10^\circ$  to  $25^\circ$  favours this reaction at the expense of the formation of higher oxidation products, only a slight excess of  $\text{BzO}_2\text{H}$  being necessary to ensure complete removal of cystine (essential).  $\text{O}_2$  consumption in the non-aq. solution is controlled by titration of the I liberated from *N*-KI-0.05N- $\text{H}_2\text{SO}_4$ , and cystine removal by colorimetric determination (cyanide-nitroprusside). The effects of varying the cystine/ $\text{BzO}_2\text{H}$  ratio, total concn., and temp. are tabulated. Oxidation of (I) by I:  $\text{R}\cdot[\text{SO}]_2\cdot\text{R} + 3\text{I}_2 + 4\text{H}_2\text{O} \rightarrow 2\text{R}\cdot\text{SO}_2\text{H} + 6\text{HI}$  (a), and reduction by KI-HCl:  $(\text{I}) + 4\text{HI} \rightarrow (\cdot\text{SR})_2 + 2\text{I}_2 + 2\text{H}_2\text{O}$ , are almost quant. The isoelectric point of (I) is at  $p_H$  3.

VI. Various decomp. of (I) are studied by determination of the intermediate oxidising val. by use of reaction (a) (complete in 1—2 hr. with 1—2*N*-HCl-KI), and by determination of cystine (above). Aq. solutions of (I) undergo dismutative decomp. with formation of cystine (to an equilibrium val. of 33 mol. %), and acid derivatives, the rate of decomp. increasing with increasing  $p_H$  and rise of temp. In alkaline solution decomp. occurs thus:  $3(I) + 4NaOH \rightarrow (\cdot SR)_2 + 4R \cdot SO_2Na$ , isolation of the sulphinic acid, decomp. 152—153° (corr.),  $[\alpha]_{D}^{25} + 33.4^\circ$  in *N*-HCl, +11° in  $H_2O$ , -23.8° as its Na salt, being described. In acid solution, decrease in available intermediate O occurs, but the equation  $3(I) + 2H_2O \rightarrow (\cdot SR)_2 + 2R \cdot SO_2H + R \cdot SH \cdot O + R \cdot SO_3H$ , approx. represents the data. With cysteine, in either acid or alkaline solution, (I) reacts almost instantaneously:  $(I) + RSH \rightarrow (\cdot SR)_2 + R \cdot SO_2H$ , the sulphinic acid then reacting slowly with cysteine:  $R \cdot SO_2H + 3RSH \rightarrow 2(\cdot SR)_2 + 2H_2O$ . Similar reaction occurs with  $H_2S$ , thioglycolic acid, and *p*-thiocresol [ $(\cdot S \cdot C_6H_4Me \cdot p)_2$  isolated].  $2(I) + 2ArSH \rightarrow (\cdot SR)_2 + (\cdot SAr)_2 + 2R \cdot SO_2H$ . With NaCN the reaction is  $(I) + NaCN \rightarrow R \cdot SCN + R \cdot SO_2Na$ , and with phosphorus acid a blue colour develops at  $p_H$  5.2, probably due to formation of cysteine:  $2(I) + H_2O \rightarrow 2RS \cdot OH + 2R \cdot SO_2H$ ;  $2RS \cdot OH \rightarrow RSH + R \cdot SO_2H$ , which is thus prevented from further reaction with (I).

J. W. B.

Reduction of cystine by sodium sulphite. T. CHEN (Chinese J. Physiol., 1936, 10, 187—189).—One mol. of cystine yields only one mol. of cysteine (I) on reduction by  $Na_2SO_3$ , whilst by electrolysis 2 mols. of (I) are produced.

J. N. A.

Nickel nitroprusside reaction for reduced glutathione. D. ZIMMET (Arch. Sci. phys. nat., 1935, [v], 17, Suppl., 225—226).—The use of a reagent containing 5 g. of  $NiCl_2$  and 5 c.c. of a 10% solution of  $Na_2Fe(NO)(CN)_5$  made up to 100 c.c., for the detection of reduced glutathione (I) is described. In the presence of (I) the colour of the reagent changes from pale green to pale pink. 1 p.p.m. of (I) can thus be detected. The necessity of adding a base as in the nitroprusside test for (I) is avoided. Advantages of the new method are the greater persistence of the colour and the absence of any colour reaction with  $COMe_2$ .

E. A. H. R.

Synthesis of cyanamide by oxidation of formaldehyde and ammonia. R. FOSSE and P. DE GRAEVE (Compt. rend., 1936, 202, 799—803).—Oxidation of  $(CH_2O)_n$  in aq.  $NH_3$  with  $CaMn_2O_8$  gave a small yield of  $CN \cdot NH_2$ , which could be oxidised to  $HCNO$  and  $HCN$ .

J. N. A.

Sensitive colour reaction of carbamide. J. A. SANCHEZ (Ann. Chim. Analyt., 1936, [iii], 18, 65—66).—A solution of  $CO(NH_2)_2$  is evaporated down with aq.  $NHPh \cdot NH_2 \cdot HCl$  and heated at 160—170° for 5 min. The product is heated at 100° with a 0.5% solution of vanillin in conc. HCl. In presence of  $CO(NH_2)_2$ , urethanes, or carbazides a cerise coloration is obtained.

J. S. A.

Nitrosomethylcarbamide. F. ARNDT (Org. Syntheses, 1935, 15, 48—50).—Improved preps. from  $NH_2Me \cdot HCl$  and from  $Me_2SO_4$  are described.

CH. ABS. (r)

Transformation products of some hydrazides of organic acids. III. (SIGNA.) M. FRERI (Gazzetta, 1936, 66, 23—30; cf. A., 1934, 1372).—Me isocrotonate or chloroisocrotonate and  $N_2H_4 \cdot H_2O$  yield 5-methylpyrazolone.  $Me_2$  itaconate, b.p. 105°/12 mm. (new prep. using  $Me_2SO_4$ ), forms the dihydrazide, m.p. 150° (dibenzylidene derivative, m.p. 220°), which gives the diazide, m.p. 50° (decomp.). Mesocon-dihydrazide, m.p. 215° (decomp.), and -diazide, m.p. 111° (decomp.), are similarly obtained. Citracondihydrazide, m.p. 177° (dibenzylidene derivative, m.p. 222°), in dil. solution is converted by  $HNO_3$  in HCl into the diazide, m.p. 114° (decomp.), and in AcOH into 3:6-diketo-4-methyltetrahydropyridazine, m.p. 277°, whilst in conc. solution in HCl it gives 4-oximino-3-methyl-5-pyrazolone, m.p. 232° (decomp.) (K and Ag salts; Bz, m.p. 177°, and *p*-nitrobenzoyl, m.p. 188°, derivatives). The last is oxidised by  $O_2 + O_3$  in KOH to nitromethylpyrazolone, m.p. 276°, and is reduced ( $SnCl_2$ ) to the hydrochloride, m.p. 225°, of aminomethylpyrazolone [*p*-nitrobenzylidene, m.p. 257° (decomp.), anisylidene, m.p. 202—203°, and piperonylidene, m.p. 245°, derivatives]. The hydrochloride is oxidised by  $H_2O_2$  to a "rubazonic acid,"  $Me \cdot C_3H_2ON_2 \cdot N \cdot C_3HON_2 \cdot Me$ , m.p. 282—283° (decomp.); this is reduced ( $SnCl_2$ ) to 5:5'-diketo-3:3'-dimethyl-4:4'-dipyrazolylammonium chloride, m.p. 247° (decomp.), which is easily re-oxidised.

E. W. W.

Fluorination of silver cyanide. I. O. RUFF and M. GIESE (Ber., 1936, 69, [B], 598—603).— $Hg(CN)_2$  burns in  $F_2$  after being gently heated at one point in a  $SiO_2$  tube, giving essentially  $CF_4$ ,  $N_2$ , and  $HgF_2$ ;  $SiF_4$  and  $CO_2$  from the tube and  $C_2N_2$  from the original material are also obtained. A violent explosion ensues when  $AgCN$  and  $F_2$  come in contact at room temp., but the reaction can be controlled if  $AgCN$  is mixed with  $CaF_2$  and  $F_2$  is used under diminished pressure.  $AgF$  remains and is ultimately converted into  $AgF_2$ . The volatile products contain  $N_2$ ,  $CF_4$ , trifluoronitrosomethane, b.p.  $\sim -80^\circ/760$  mm., m.p.  $\sim -150^\circ$ ,  $CF_3 \cdot NF_2$ ,  $SiF_4$ ,  $COF_2$ ,  $CO_2$ ,  $N_2O$ ,  $C_2F_6$ , a mixture of isomerides  $(CNF_3)_2$ , and a mixture  $(CNF_4)_2$ . The course of the change is represented:  $Ag \cdot N \cdot C + F_2 \rightarrow Ag \cdot N \cdot CF_2$  (I);  $(I) + F_2 \rightarrow AgF + NF \cdot CF_2$  (II). (II) is exceedingly unstable by reason of the double linking and polymerises in many directions, mainly towards  $(CNF_3)_2$  with some production of  $(CN_3F)_3$  and production of combined polymerised substances. Further fluorination of  $CNF_3$  gives  $(CNF_4)_2$ ,  $CNF_5(NF_2 \cdot CF_3)$ , and  $C_3F_6$ . The presence of O in the  $AgCN$  gives rise to  $CF_3 \cdot NO$  and  $N_2O$  whilst  $SiO_2$  is the source of  $SiF_4$ ,  $COF_2$ , and  $CO_2$ .

H. W.

Isomerism of dicyanohexafluoride,  $C_2N_2F_6$ . II. O. RUFF and M. GIESE (Ber., 1936, 69, [B], 604—607).—The crude  $C_2N_2F_6$  is treated first with  $NH_3$  and then with  $Hg$  whilst a second portion is treated with the reagents in the reverse order, and the products are analysed. In evaluating the results

the following considerations are involved.  $\text{NH}_3$  reacts particularly on the  $\text{CF}_2\text{:N}\cdot$  and  $\cdot\text{CF:N}$  double linkings, Hg only on mobile F attached to N in  $\cdot\text{NF}$ . This is shown by the instability of unimol.  $\text{CF}_2\text{:NF}$  (which is not present among the products of the action of F on  $\text{AgCN}$ ) and by the observation that  $\cdot\text{NF}$  is far less stable than  $\cdot\text{NF}_2$  ( $\text{CF}_3\cdot\text{NF}_2$  is remarkably stable) whilst F is not removed from CF by Hg.  $\text{NH}_3$  is added to fluorinated N:C linkings and causes their fission with elimination of N. In presence of  $\text{NH}_3$  H cannot exist in union with a fluorinated C atom to which a fluorinated N is attached;  $\text{NH}_4\text{F}$  is produced with brown substances containing  $\text{C:N:F}=2:1:1$ . The chemically less active forms are regarded as *trans* varieties, increasing reactivity being shown by the *cis*- and *as*-forms. On this basis the isomerides  $\text{CF}_3\text{:N:N}\cdot\text{CF}_3$  (*cis*- and *trans*-),  $\text{CF}_3\text{:N}\cdot\text{CF}\cdot\text{NF}_2$  (*cis*- and *trans*-),  $\text{CF}_2\text{:N}\cdot\text{CF}_2\cdot\text{NF}_2$ , and  $\text{CF}_2\text{<}\begin{smallmatrix} \text{NF} \\ \text{NF} \end{smallmatrix}\text{>CF}_2$  or  $\text{CF}_2\text{<}\begin{smallmatrix} \text{CF}_2 \\ \text{NF} \end{smallmatrix}\text{>NF}$  are shown to be present. H. W.

**Action of thiocyanogen on unsaturated hydrocarbons.** A. KRASSILCHIK (Ann. Off. nat. Combust. liq., 1935, 10, 923—987).—The CNS method of determining unsaturation is more trustworthy than the Winkler-Dubowitz Br method. The prep. and use of the reagent are described. With 300% excess of CNS the reaction is bimol. and is practically complete in 10—40 hr. with absorption 60—95% of theoretical depending on the hydrocarbon. Certain hydrocarbons like stilbene do not react. Addition of I in AcOH is not as regular as that of CNS and is greatly influenced by traces of Cl or Br. Differences in the rate of addition of CNS may be used to fractionate mixtures of olefines, e.g., a mixture of  $\Delta^a$ - and  $\Delta^b$ -octene. R. B. C.

**Diazomethane.** F. ARNDT (Org. Syntheses, 1935, 15, 3—5).—An improved prep. from  $\text{NH}_2\cdot\text{CO}\cdot\text{NMe}\cdot\text{NO}$  is described. CH. ABS. (r)

**Quantitative studies of organometallic compounds.** E. A. ZOELLNER (Iowa State Coll. J. Sci., 1934, 9, 213—214).—The yields of  $\text{MgRHal}$  obtained from a large no. of alkyl halides under various conditions are given; the practical significance of the results is discussed. CH. ABS. (r)

**Organic magnesium compounds. II. Reactions of aryl *p*-toluenesulphonates with Grignard reagents.** K. MINE (J. Chem. Soc. Japan, 1934, 55, 1087—1090; cf. A., 1935, 739).—Two reactions occur: (i)  $\text{R}\cdot\text{SO}_3\text{R}' + \text{MgXR}'' \rightarrow \text{R}\cdot\text{SO}_2\cdot\text{R}' + \text{OR}'\cdot\text{MgX}$  and (ii)  $\text{R}\cdot\text{SO}_3\text{R}' + \text{MgXR}'' \rightarrow \text{R}\cdot\text{SO}_2\cdot\text{OMgX} + \text{R}' + \text{R}''$ ; when  $\text{R}' = \text{aryl}$  (i) is the main reaction, but is replaced by (ii) when  $\text{R}' = \text{alkyl}$ . CH. ABS. (r)

**Photolysis of lead tetramethyl and lead tetraphenyl.**—See this vol., 573.

**Bisdimethylglyoxime diamine cobaltic salts and their configuration.** Y. NAKATSUKA and H. INUMA (Bull. Chem. Soc. Japan, 1936, 11, 48—54; cf. A., 1935, 51).—An EtOH solution of  $\text{CoCl}_3$  and of  $\text{OH}\cdot\text{N}:\text{CMe}\cdot\text{CMe}:\text{N}\cdot\text{OH}$  ( $\Delta\text{H}_2$ ) treated with aq.  $\text{NH}_3$  or with an org. base (*B*) and allowed to oxidise in the air gives compounds of type  $[\text{CoB}_2(\Delta\text{H})_2]\text{Cl}$ , from which

other salts are obtainable. In this way the *chlorides* in which  $B = \text{NH}_3$ ,  $\text{NH}_2\text{Ph}$ , *o*- and *p*- $\text{C}_6\text{H}_4\text{Me}\cdot\text{NH}_2$ , *m*-4- $\text{C}_6\text{H}_3\text{Me}_2\cdot\text{NH}_2$ , and  $\alpha$ - and  $\beta$ - $\text{C}_{10}\text{H}_7\cdot\text{NH}_2$ , are prepared, and in most cases converted into the *bromides*, *iodides*, *thiocyanates*, *nitrates*, *sulphates*, and *H sulphates*; the *bases*

$[\text{Co}(p\text{-C}_6\text{H}_4\text{Me}\cdot\text{NH}_2)_2(\Delta\text{H})_2]\text{OH}\cdot 2\text{H}_2\text{O}$  and  $[\text{Co}(\beta\text{-C}_{10}\text{H}_7\cdot\text{NH}_2)_2(\Delta\text{H})_2]\text{OH}\cdot 2\text{H}_2\text{O}$  are also prepared. Since *o*- $\text{C}_6\text{H}_4(\text{NH}_2)_2$  gives the *chloride*  $[\text{Co}(o\text{-NH}_2\cdot\text{C}_6\text{H}_4\cdot\text{NH}_2)_2(\Delta\text{H})_2]\text{Cl}\cdot 4\text{H}_2\text{O}$ , and not one containing 1 mol. of *o*- $\text{C}_6\text{H}_4(\text{NH}_2)_2$  with both  $\text{NH}_2$  coordinated, the groups of the bases must be in *trans* configuration, and those of ( $\Delta\text{H}$ ) must lie in the same plane. In presence of NaOH, a compound  $[\text{Co}(o\text{-NH}_2\cdot\text{C}_6\text{H}_4\cdot\text{NH}_2)_2(\Delta\text{H})_2]\text{Cl}\cdot 4\text{H}_2\text{O}$ , containing non-ionisable Cl, is obtained.  $[\text{Co}(\Delta\text{H}_2)_2]\text{Cl}_2$  treated in  $\text{COMe}_2$  with  $\text{NH}_3$  or  $\text{NH}_2\text{Ph}$  gives the same compound, and not one of type  $[\text{CoB}_2(\Delta\text{H})_2]\text{Cl}$ ; if, however, *o*- $\text{C}_6\text{H}_4(\text{NH}_2)_2$  is used, the compound  $[\text{Co}(o\text{-NH}_2\cdot\text{C}_6\text{H}_4\cdot\text{NH}_2)_2(\Delta\text{H}_2)_2(\text{H}_2\text{O})]\text{Cl}_2\cdot \text{COMe}_2$  is obtained, from which  $\text{H}_2\text{O}$  is not lost at  $110^\circ$  or over  $\text{H}_2\text{SO}_4$ , and which in  $\text{H}_2\text{O}$  has an acid reaction, owing apparently to the formation of  $[\text{Co}(o\text{-NH}_2\cdot\text{C}_6\text{H}_4\cdot\text{NH}_2)_2(\Delta\text{H}_2)_2(\text{OH})]\text{Cl} + \text{HCl}$ . E. W. W.

**Phosphoric oxide, catalyst for polymerisation of unsaturated hydrocarbons.** Decahydrodiphenyl obtained by dimerisation of *cyclohexene*. R. TRUFFAULT (Bull. Soc. chim., 1936, [v], 3, 442—459).—1-*cyclohexyl*- $\Delta^1$ -*cyclohexene* (I), b.p.  $103\text{—}105^\circ/12\text{ mm.}$ ,  $238\text{—}239^\circ/760\text{ mm.}$ , m.p. about  $-45^\circ$ , is obtained in 80—90% yield when *cyclohexene* (II) is condensed on  $\text{P}_2\text{O}_5$  (using a Soxhlet apparatus). (I) is reduced ( $\text{H}_2$ , Ni—Cr, hexane, room temp.) at nearly the same rate as (II), and is oxidised ( $\text{CrO}_3$ , AcOH) to adipic and  $\epsilon$ -keto- $\epsilon$ -*cyclohexylhexoic* acids. (I) and  $\text{HHal}$  in  $\text{CHCl}_3$  at  $0^\circ$  give 1-*chloro*-, m.p.  $40^\circ$  (similarly obtained from 1-*cyclohexylcyclohexanol*), 1-*bromo*-, m.p.  $46^\circ$  [converted by boiling  $\text{H}_2\text{O}$  or  $\text{AgOH}$  into (I)], and 1-*iodo*-, m.p.  $52^\circ$ , -*dicyclohexyl*. (I) and Br in  $\text{CHCl}_3$  at  $0^\circ$  afford 25% of (probably) 1:2:1'-*tribromodicyclohexyl*, m.p.  $127^\circ$ . (I) is also obtained in much smaller yield from (II) and  $\text{H}_3\text{PO}_4$ ;  $\text{HPO}_3$  is not a catalyst. (II) and 85%  $\text{H}_2\text{SO}_4$  give (cf. Brooks and Humphrey, A., 1918, i, 286; Nametkin and Abakumovskaja, A., 1933, 152, 385) 23% of *cyclohexanol* and 48% of *cyclohexyl H sulphate* or *cyclohexanesulphonic acid*.  $\text{P}_2\text{O}_5$  is a good catalyst for the prep. of diamylene (from  $\text{C}_5\text{H}_{10}$ ) and a hydrocarbon,  $\text{C}_{20}\text{H}_{32}$  (from limonene). H. B.

$\Delta^{1:3}$ -*cyclohexadiene* and structure of its monoxide. P. BEDOS and A. RUYER (Compt. rend., 1936, 202, 671—673; cf. A., 1933, 500).—Successive treatment of the dibromide (I), m.p.  $108^\circ$ , of  $\Delta^{1:3}$ -*cyclohexadiene* (II) with  $\text{AgOAc}$  and dry KOH in  $\text{Et}_2\text{O}$  gives the oxide (III) of (II). (III) and  $\text{H}_2\text{O}$  at  $0^\circ$  afford the *cyclohexenediols* previously described (*loc. cit.*). (III) and  $\text{PBr}_5$  in  $\text{Et}_2\text{O}$  give (I) and a liquid isomeride (cf. Farmer and Scott, A., 1929, 304). (III) does not immediately decolorise Br in  $\text{CCl}_4$  unless a little  $\text{H}_2\text{O}$  is present; it reacts slowly with  $\text{BzO}_2\text{H}$  to give the dioxide (*loc. cit.*). It is unlikely that (III) is a mixture (cf. *loc. cit.*); the activity of the double linking present is reduced whilst the oxide reactions

are enhanced. The Raman spectra of (II) and (III) are given; (III) shows the frequency characteristic of the double linking, whilst that at  $1581\text{ cm}^{-1}$  for (II) is considered to be due to the conjugated double linkings. H. B.

**Orienting rule of Svirebely and Warner.** K. GANAPATHI (Current Sci., 1936, 4, 482).—Various derivatives with electric moments  $> 2.07 D$  yield *o*- and *p*-products, and not *m*- as required by this rule (A., 1935, 684), which further fails to explain why a *m*-directing group R, of high moment, becomes *o*- and *p*-directing when in the group  $\cdot\text{CH}_2\text{R}$  or  $\cdot\text{CH}_2\cdot\text{CH}_2\text{R}$ , of similar moment. E. W. W.

**Aromatic hydrocarbons. XX. Simple principle of the structure of aromatic hydrocarbons and their absorption spectra.** E. CLAR (Ber., 1936, 69, [B], 607—614).—Examination of the absorption spectra of  $\text{C}_6\text{H}_6$ ,  $\text{C}_{10}\text{H}_8$ , anthracene, benzanthracene, and dibenzanthracene shows that the square roots of the absorption frequencies are inversely to 6, 7, 8, 9, and 10. Similar comparison of  $\text{C}_2\text{H}_6$ ,  $\text{C}_2\text{H}_4$ ,  $\text{C}_6\text{H}_6$ , phenanthrene, and dibenzphenanthrene gives the figures 6, 7, 8, 9, and 10. The reasons are discussed. H. W.

**Raman effect and problems of constitution. IX. Stability of the aromatic C-X linking.** K. W. F. KOHLRAUSCH (Ber., 1936, 69, [B], 527—532; cf. this vol., 136, 137).—It is shown mathematically that in compounds  $\text{PhX}$  ( $\text{X}=\text{I}, \text{Br}, \text{SH}, \text{Cl}, \text{Me}, \text{F}, \text{OH}, \text{NH}_2$ ),  $p\text{-C}_6\text{H}_4\text{X}_2$ , and  $1:3:5\text{-C}_6\text{H}_3\text{X}_3$  the individual substituents have no important constitutive influence on the ring and that all C-X linkings are similarly affected by the transition from the aliphatic to the aromatic C atom. The change in the strength of union on entrance of a new C-X linking is almost independent of the presence or absence of a second C-X linking in the *m*- or *p*-position. The aromatic C-X linking is about 20% stronger than the aliphatic linking. H. W.

**Oxidation of aromatic hydrocarbons at high pressures. I. Benzene. II. Toluene. III. Ethylbenzene.** D. M. NEWITT and J. H. BURGONNE (Proc. Roy. Soc., 1936, A, 153, 448—462).—At suitable temp. and pressures the slow combustion of  $\text{C}_6\text{H}_6$  proceeds smoothly without any induction period or sudden change in reaction velocity, whereas  $\text{PhMe}$  and  $\text{PhEt}$  exhibit well-marked induction periods, and in each case oxidation of the nucleus and side-chains occurs simultaneously. Combustion takes place by hydroxylation of either the ring or the side-chain, giving as primary products  $\text{PhOH}$  and alcohols respectively. For comparable rates of reaction,  $\text{C}_6\text{H}_6\text{-O}_2$  mixtures require a higher temp. than either  $\text{PhMe-O}_2$  or  $\text{PhEt-O}_2$  mixtures of similar composition. Increased surface retards the rate of oxidation of  $\text{C}_6\text{H}_6$  but has no effect on  $\text{PhMe}$  or  $\text{PhEt}$ ; the addition of  $\text{N}_2$  retards all three reactions equally. Probably a "chain" mechanism is involved in each case, but a difference exists in the chain-propagating reactions according to whether oxidation of the nucleus or side-chain is taking place. The course of combustion up to the point at which rupture of the ring occurs may be represented:  $\text{C}_6\text{H}_6 \rightarrow$

$\text{PhOH} \rightarrow 1:4\text{-C}_6\text{H}_4(\text{OH})_2 \rightarrow 1:2:4\text{-C}_6\text{H}_3(\text{OH})_3 \rightarrow \text{C}_6\text{H}_4\text{O}_2 \rightarrow \text{ring ruptures}$ . In suitable circumstances, as much as 53.5% of the C of the  $\text{C}_6\text{H}_6$  burnt appears as  $\text{PhOH}$ .  $\text{PhMe} \rightarrow \text{CH}_2\text{Ph}\cdot\text{OH} \rightarrow \text{CHPh}(\text{OH})_2 \rightarrow \text{H}_2\text{O} + \text{PhCHO} \rightarrow \text{BzOH} \rightarrow \text{ring ruptures}$ . Oxidation of the nucleus gives mainly  $2:4\text{-C}_6\text{H}_3\text{Me}(\text{OH})_2$ . Under suitable conditions either one of the side-chain derivatives may be obtained in optimum amounts.  $\text{PhEt} \rightarrow \text{CHPhMe}\cdot\text{OH} \rightarrow \text{CPhMe}(\text{OH})_2 \rightarrow \text{COPhMe} \rightarrow \text{COPh}\cdot\text{CH}_2\cdot\text{OH} \rightarrow \text{COPh}\cdot\text{CH}(\text{OH})_2 \rightarrow \text{PhCHO} \rightarrow \text{BzOH} \rightarrow \text{ring ruptures}$ . Oxidation of the nucleus gives mainly  $2:4\text{-C}_6\text{H}_3\text{Et}(\text{OH})_2$ .

L. L. B.

**Chlorination of benzene.** F. F. KRIVONOS (Ukrain. Chem. J., 1935, 10, 417—427).—Stirring the  $\text{C}_6\text{H}_6$  during chlorination leads to diminution in the amount of polychlorides formed, and to a greater yield of  $\text{PhCl}$ . R. T.

**Halogenation. XIII. Bromination and iodination of some halogenated benzenes.** P. S. VARMA and S. SHANKARARAYANAN (J. Indian Chem. Soc., 1936, 13, 31—33).—Substitution of  $p\text{-C}_6\text{H}_4\text{Cl}_2$ ,  $\text{PhBr}$ ,  $p\text{-C}_6\text{H}_4\text{Br}$ , and  $\text{PhI}$  by  $\text{Br}$  and  $\text{I}$  in presence of halogenating agents gives known derivatives of  $\text{C}_6\text{H}_6$ . F. R. G.

**Replacement of chlorine by fluorine in organic compounds.** H. B. GOTTLIEB (J. Amer. Chem. Soc., 1936, 58, 532—533).— $2:4\text{-(NO}_2)_2\text{C}_6\text{H}_3\text{Cl}$  with successive amounts of anhyd.  $\text{KF}$  in  $\text{PhNO}_2$  at  $205^\circ$  gives 30% of  $2:4\text{-(NO}_2)_2\text{C}_6\text{H}_3\text{F}$ , m.p.  $24\text{--}25^\circ$ , which reacts slowly with  $\text{H}_2\text{O}$  at  $60^\circ$  forming  $\text{HF}$ . *Diphenoxyphosphoryl fluoride*, b.p.  $150\text{--}155^\circ/6\text{ mm.}$ , similarly prepared in 7% yield from  $(\text{OPh})_2\text{POCl}$  at  $90\text{--}100^\circ$ , is decomposed rapidly by  $\text{H}_2\text{O}$  and when distilled in a vac. undergoes partial decomp. to  $\text{Ph}_3\text{PO}_4$  and  $\text{POF}_3$ . H. B.

**Chlorination of toluene in presence of (a) activated charcoals, and (b) iron-impregnated silica gel. Production of side-chain substitution, nuclear substitution, and tolan derivatives.** J. B. FIRTH and T. A. SMITH (J.C.S., 1936, 337—339).—Addition of heat-activated sugar-C, better if iodised or Fe-impregnated, increases the rate of chlorination and amount of side-chain substitution of  $\text{PhMe}$  in the dark. Prolonged reaction gives  $2:2'\text{-dichlorotolan dichloride}$ , b.p. about  $220^\circ/30\text{ mm.}$ , m.p. of isomerides between  $139^\circ$  and  $170^\circ$ . Fe-impregnated  $\text{SiO}_2$  gel increases nuclear substitution, giving  $2:4:5\text{-C}_6\text{H}_2\text{Cl}_3\text{Me}$  and a substance,  $\text{C}_{14}\text{H}_{10}\text{Cl}_2$ , m.p.  $145^\circ$ , and much glue-like material.  $\text{CH}_2\text{PhCl}$  and  $\text{SiO}_2$  gel give a similar glue exothermally. R. S. C.

**Velocity of reaction between *o*-nitrobenzyl bromide and pyridine. Mechanism of side-chain reactions, etc.** IV. J. W. BAKER (J.C.S., 1936, 399—400; cf. this vol., 195).— $o\text{-NO}_2\text{C}_6\text{H}_4\text{-CH}_2\text{Br}$  reacts with  $\text{C}_5\text{H}_5\text{N}$  slightly faster than does  $\text{CH}_2\text{PhBr}$ , but not fast enough for the *o*- $\text{NO}_2$  to account for the much faster reaction of the  $2:4\text{-(NO}_2)_2$ -compound. R. S. C.

**Derivatives of *tert*-butylbenzene and transmitted polar effects.** (THE LATE) J. B. SHOE-SMITH and A. MACKIE (J.C.S., 1936, 300—303).—Boiling *m*- and *p*- $\text{C}_6\text{H}_4\text{MeBu}^t$  and  $\text{Br}$  give *m*-, b.p.

115.5°/8 mm., and *p*-tert.-butylbenzyl bromide (I), m.p. 12–13°, b.p. 132.5°/14 mm., oxidised to *m*-, m.p. 127°,  $k$   $5.2 \times 10^{-5}$ , and *p*-C<sub>6</sub>H<sub>4</sub>Bu<sup>γ</sup>CO<sub>2</sub>H, m.p. 165° (lit. 164°),  $k$   $4.2 \times 10^{-5}$ , respectively. (I) and HI-AcOH give *p*-tert.-butylbenzyl iodide, m.p. 29.5–30.5°. The relative vals. of  $k$  of the acids and of the rates of hydrolysis of the bromides in aq. EtOH ( $p > m$ -Bu<sup>γ</sup> > unsubstituted) indicate both electro-merie and inductive effects due to Bu<sup>γ</sup>, but the relative ease of reduction of the bromides by HI ( $m > p$ -Bu<sup>γ</sup> > unsubstituted) requires an additional explanation not yet apparent. R. S. C.

***o*-Nitrophenylsulphur chloride (*o*-nitrobenzenesulphenyl chloride).** M. H. HUBACHER (Org. Syntheses, 1935, 15, 45–47).—NO<sub>2</sub>·C<sub>6</sub>H<sub>4</sub>·SCl is obtained by the action of Cl<sub>2</sub> in CCl<sub>4</sub> on (o-NO<sub>2</sub>·C<sub>6</sub>H<sub>4</sub>·S)<sub>2</sub>. CH. ABS. (r)

**Mechanism of additive reactions. Kinetic study of addition of methyl hypobromite to stilbene.** P. D. BARTLETT and D. S. TARBELL (J. Amer. Chem. Soc., 1936, 58, 466–474).—Reaction between (·CHPh)<sub>2</sub> and Br in MeOH at 0°, whereby OMe·CHPh·CHPhBr (I) is formed in 99% yield, is not inhibited by O<sub>2</sub>. The rate is steadily diminished by increased concn. of added Br<sup>-</sup> (using solutions of const. ionic strength 0.2, containing NaBr supplemented by PhSO<sub>3</sub>Li); the yield of (I) also decreases (83% in presence of 0.2M-NaBr) whilst that of (·CHPhBr)<sub>2</sub> increases. The rate is not, however, diminished by H<sup>+</sup>, indicating that MeOBr is not responsible for the production of (I). The kinetics are of the second order only when the initial concn. of Br<sup>-</sup> is much > that formed during the reaction; they indicate a two-stage mechanism with mol. Br as the active agent. The results are inconsistent with any mechanism attributing activity to Br<sup>+</sup> or to MeOBr catalysed by acid. The following changes are considered to occur: (·CHPh)<sub>2</sub> + Br<sub>2</sub> → CHPhBr·CHPh (II) + Br<sup>-</sup>; (II) + MeOH → (I) + H<sup>+</sup>; (II) + Br<sup>-</sup> → (·CHPhBr)<sub>2</sub>. H. B.

**Structure of naphthalene.** E. BERGMANN and J. HIRSBERG (J.C.S., 1936, 331–336).—The effect of 2-Cl on  $k$  of 1-C<sub>10</sub>H<sub>7</sub>·CO<sub>2</sub>H and of 1- and 3-Cl on  $k$  of 2-C<sub>10</sub>H<sub>7</sub>·CO<sub>2</sub>H and on the rates of hydrolysis of the esters is not identical, indicating that the C1–C2 and C2–C3 linkings differ in nature and that the linkings in C<sub>10</sub>H<sub>8</sub> are static. Some close effect (possibly steric) is exerted by 1- and 8-substituents on one another, particularly noticeable in dipole moments. 3-Amino-2-naphthoic acid yields *Et* 3-chloro-2-naphthoate, b.p. 195–197°/18 mm., m.p. 57–59°. 9:1-C<sub>10</sub>H<sub>6</sub>Cl·CO<sub>2</sub>H, m.p. 169–170° (*Me* ester, b.p. 188–189°/16.2 mm.), *Me* 1-chloro-2-naphthoate, m.p. 48–49°, 2-, m.p. 76°, and 1-naphthoate, b.p. 165°/17 mm., and 2-chloro-1-naphthoate, b.p. 176–180°/18.5 mm., m.p. 50°, are described. 8:1-C<sub>10</sub>H<sub>6</sub>Cl·NH<sub>2</sub> gives the diazonium borofluoride, m.p. 106–107° (decomp.), and leads to 1-chloro-8-fluoro-, m.p. 44°, b.p. 130–132°/12.5 mm., -bromo-, m.p. 94–95° (lit. 87–88°, 119°), and -iodo-naphthalene, m.p. 79–80°, b.p. 197–198°/19 mm., 1:8-C<sub>10</sub>H<sub>6</sub>Cl<sub>2</sub>, m.p. 84–85°, and 9-chloro-1-naphthonitrile, m.p. 145–146°, b.p. 242–244°/15.5 mm. R. S. C.

**Nitration of polycyclic aromatic hydrocarbons by means of nitrous fumes.** (SIGNA.) L. MONTI, V. MARTELLO, and F. VALENTE (Gazzetta, 1936, 66, 31–38).—Acenaphthene treated in Et<sub>2</sub>O or in light petroleum at 15–16° with nitrous fumes yields 3-nitroacenaphthene; in C<sub>6</sub>H<sub>6</sub> or AcOH at 8–10°, or with liquid N<sub>2</sub>O<sub>4</sub>, the 3:4-(NO<sub>2</sub>)<sub>2</sub>-compound is formed. Fluorene in any of these solvents at low temp. gives 2-nitrofluorene; in AcOH at 90–95°, a mixture of the 2:5- and 2:7-(NO<sub>2</sub>)<sub>2</sub>-compounds is obtained. Ph<sub>2</sub> is unchanged at 0–25°; in AcOH or petroleum at 90–95°, or with liquid N<sub>2</sub>O<sub>4</sub> at room temp., 4-nitrodiphenyl is formed, whilst prolonged action of nitrous fumes at 90–95° yields a mixture of the 4:4'- and 4:2'-(NO<sub>2</sub>)<sub>2</sub>-compounds. CHPh<sub>3</sub> is not nitrated, but gives CPh<sub>3</sub>·OH, or, at 0° in EtOH, its nitrite. CH<sub>2</sub>Ph<sub>2</sub> and (·CH<sub>2</sub>Ph)<sub>2</sub> are not appreciably nitrated. E. W. W.

**Thermolysis of cholesteryl chloride.** E. BERGMANN and F. BERGMANN (Chem. and Ind., 1936, 272–273).—When heated for 3 hr. at 300° in dry N<sub>2</sub>, cholesteryl chloride affords (by loss of 1 mol. of HCl) a distillate, b.p. 118–125°/758.5 mm., containing 75–67% of C<sub>8</sub>H<sub>18</sub> and 25–33% of C<sub>8</sub>H<sub>16</sub>, and a residue from which are isolated (1) a small amount of a hydrocarbon (C, 88.8; H, 11.2%), b.p. 156–157°/30 mm., [α]<sub>D</sub> +17.3° in C<sub>6</sub>H<sub>6</sub>; (2) a hydrocarbon C<sub>15</sub>H<sub>28</sub> or (?) C<sub>16</sub>H<sub>24</sub>, b.p. 150–155°/0.03 mm., [α]<sub>D</sub> +34.9° in C<sub>6</sub>H<sub>6</sub>, containing 2 double linkings, one of which is resistant to Br-titration (partial structure suggested); and (3), the main fraction, a tetracyclic hydrocarbon C<sub>19</sub>H<sub>30</sub> (lit. C<sub>19</sub>H<sub>28</sub>), b.p. 180–185°/0.02 mm., [α]<sub>D</sub> +31.4° in C<sub>6</sub>H<sub>6</sub>, containing only 1 double linking, showing that pyrolysis is accompanied by H transfer. J. W. B.

**[Reversible chemical absorption of free oxygen by organic compounds.]** A. SCHÖNBERG (Ber., 1936, 69, [B], 532–533).—A question of priority regarding rubenes. H. W.

**Reversible oxidisability of organic compounds. Reducible, but not dissociable, monoxide of diphenyldi-*p*-bromophenylrubene.** L. ENDERLIN (Compt. rend., 1936, 202, 669–671; cf. A., 1935, 650).—The oxide (I), C<sub>42</sub>H<sub>26</sub>OBr<sub>2</sub>, m.p. 284–285° (when free from solvent of crystallisation), most simply prepared by oxidation (15% HNO<sub>3</sub> in C<sub>6</sub>H<sub>6</sub>) of diphenyldi-*p*-bromophenylrubene (II), is not dissociable by heat but is reduced (Fe, AcOH) to (II). (I), which is probably an *endo*-oxide, is also obtained by dehydration of dihydroxydiphenyldi-*p*-bromophenylrubene and by partial reduction (Zn, AcOH) of the dissociable dioxide of (II). H. B.

**Interaction of sulphur dichloride with substances containing the reactive methylene group.** II. K. G. NAIK and S. A. VAISHNAV (J. Indian Chem. Soc., 1936, 13, 25–27).—SCl<sub>2</sub> with acetoacetyl-amides (I) in pure, dry C<sub>6</sub>H<sub>6</sub> gives CSAc·CO·NHR, which with Na<sub>2</sub>S yields (I) and with KOH yields NH<sub>2</sub>R. The following were prepared: α-thion-acetoacet-anilide, m.p. 196°, -*o*-, m.p. 184°, and -*p*-toluidide, m.p. 130°, -*α*-, m.p. 184°, and -β-naphthylamide, m.p. 179°, -1:4:5-, m.p. 209°, and -1:3:4-xylylide, m.p. 201°. F. R. G.

**Interaction of thionyl chloride with substances containing the reactive methylene group.** V. K. G. NAIK and S. A. VAISHNAV (J. Indian Chem. Soc., 1936, 13, 28—30).— $\text{SOCl}_2$  reacts with malonarylamides in presence of Cu with presumed intermediate formation of  $\text{SCL}_2$ ,  $\text{SO}_2$ , and  $\text{CuCl}_2$  to give  $\text{CS}(\text{CO}\cdot\text{NHR})_2$  (cf. preceding abstract). The following were prepared: *thionmalondi-phenylamide*, m.p.  $105^\circ$  (shrinks at  $80^\circ$ ), -o-, m.p.  $138^\circ$  (shrinks at  $110^\circ$ ), -p-, m.p.  $108^\circ$  (shrinks at  $60^\circ$ ), and -*m-tolylamide*, m.p.  $114^\circ$  (shrinks at  $60^\circ$ ), - $\alpha$ -*naphthylamide*, m.p.  $168^\circ$ , -1:3:4-, m.p.  $126^\circ$  (shrinks at  $95^\circ$ ), and -1:4:5-*xylylidide*, m.p.  $146^\circ$  (shrinks at  $100^\circ$ ). F. R. G.

[o- and p-Derivatives of o-toluidine.] 2:6-Diacetamidotoluene. A. KORULEV and E. ROSTOV-TZEVA (Ber., 1936, 69, [B], 640).—The non-cryst. product of the technical prep. of 1:2:4- $\text{C}_6\text{H}_3\text{Me}(\text{NO}_2)_2$  from a mixture of o- and p- $\text{C}_6\text{H}_4\text{Me}\cdot\text{NO}_2$  is reduced and acetylated. The product is treated with EtOH, which dissolves 2:4-diacetamidotoluene leaving 2:6-diacetamidotoluene (I), m.p.  $309\text{--}311^\circ$ . Since (I) is smoothly hydrolysed to 1:2:6- $\text{C}_6\text{H}_3\text{Me}(\text{NH}_2)_2$ , m.p.  $103\text{--}104^\circ$ , and obtained from 1:2:6- $\text{C}_6\text{H}_3\text{Me}(\text{NO}_2)_2$ , the m.p.  $202^\circ$  recorded for (I) by Green *et al.* (J.C.S., 1891, 59, 1017) requires correction. H. W.

**Secondary reactions in reduction of aromatic nitro-compounds. Rôle of ferrous salts in reduction process.** K. G. MISUTSCH (J. pr. Chem., 1936, [ii], 145, 60—64).— $\text{C}_6\text{H}_4\text{Hal}\cdot\text{NH}_2$  are not formed during reduction of  $\text{PhNO}_2$  by Sn (or  $\text{SnCl}_2$ ) and 6:86N-HCl, -HBr, or -HF in presence of AcOH and 1 mol. of  $\text{FeHal}_2$ . Since  $\text{NACPhCl}$  with  $\text{FeCl}_2$ -dil. HCl or HI gives  $\text{NHAcPh}$  and no  $\text{C}_6\text{H}_4\text{Cl}\cdot\text{NHAc}$ , the function of the  $\text{FeHal}_2$  (above) is to reduce the intermediate  $\text{NHPhHal}$  to  $\text{NH}_2\text{Ph}$ . Reduction (Sn, HBr) of  $\text{PhNO}_2$  in absence of  $\text{FeBr}_2$  affords p- $\text{C}_6\text{H}_4\text{Br}\cdot\text{NH}_2$  (44.85% of total amine) and small amounts of axoxybenzene and p- $\text{NH}_2\cdot\text{C}_6\text{H}_4\cdot\text{OH}$  (formed by rearrangement of  $\text{NHPh}\cdot\text{OH}$ ; this occurs much more slowly than the changes  $\text{NHPh}\cdot\text{OH} \rightarrow \text{NHPhBr} \rightarrow \text{C}_6\text{H}_4\text{Br}\cdot\text{NH}_2$ ). H. B.

**Aromatic N-substituted cyanoamides.** J. BIECHLER (Compt. rend., 1936, 202, 666—667).—p-Anisyl-, m.p.  $33^\circ$ , p-phenetyl-, m.p.  $69^\circ$ , and 4-chloro-3-aminophenyl-, m.p.  $136^\circ$ , -dicyanoamides are prepared (cf. A., 1935, 482) from  $\text{KNAr}\cdot\text{CN}$  and  $\text{CNBr}$ ; o-tolyl-, m.p.  $36^\circ$ , p-chlorophenyl-, m.p.  $59^\circ$ , and  $\alpha$ -naphthyl-, m.p.  $126^\circ$ , -dicyanoamides are similarly obtained (cf. *loc. cit.*) using  $\text{CNCl}$ .  $\text{KNPh}\cdot\text{CN}$  (I) and  $\text{CPh}_2\text{Cl}$  give phenylcyanoamidotriphenylmethane, m.p.  $124^\circ$ ;  $\text{CPh}_2\text{Cl}_2$  (?) similarly affords di(phenylcyanoamido)diphenylmethane, m.p. about  $200^\circ$ , whilst  $\text{COPh}\cdot\text{CH}_2\text{Br}$  yields phenacylphenylcyanoamide, m.p.  $123^\circ$ . (I) and  $\text{S}_2\text{Cl}_2$  give di(phenylcyanoamido)-disulphide, m.p.  $83^\circ$ ;  $\text{AsCl}_3$  affords tri(phenylcyanoamido)arsine, m.p. about  $250^\circ$ . A bromophenylcyanoamide is obtained from (I) and Br. Me, m.p.  $63^\circ$ ,  $\text{CH}_2\text{Cl}$ , m.p.  $48^\circ$ , and  $\text{CCl}_3$ , m.p.  $84\text{--}85^\circ$  (with liberation of  $\text{COCl}_2$ ), phenylcyanoamidocarbonates are prepared. H. B.

**Substituted naphthalenesulphonic acids and their derivatives.** W. M. CUMMING and G. D. MUIR (J. Roy. Tech. Coll., 1936, 3, 562—568).—Diazotised

1:8- $\text{NH}_2\cdot\text{C}_{10}\text{H}_6\cdot\text{SO}_3\text{H}$  (I) with KI and  $\text{C}_5\text{H}_5\text{N}$  (or  $\text{COMe}_2$ ) gives the 1:8-sultone, and after saturation with NaCl, the Na salt of 1:8- $\text{C}_{10}\text{H}_6\text{I}\cdot\text{SO}_3\text{H}$  (cf. A., 1934, 519). The *chloride*, m.p.  $115^\circ$ , of the latter yields, with dil. aq.  $\text{NH}_3$  in cold  $\text{COMe}_2$ , the *amide*, m.p.  $187^\circ$  (decomp.), or, in boiling  $\text{COMe}_2$ , the 1:8-naphthasultam. The *anilide*, m.p.  $140^\circ$ , is converted by Cu in boiling EtOH into the N-phenylsultam, new m.p.  $165^\circ$ . An improved prep. of 1:8- $\text{C}_{10}\text{H}_6\text{Cl}\cdot\text{SO}_3\text{H}$  from the solid diazo-compound of (I) and cold  $\text{Cu}_2\text{Cl}_2$  in conc. HCl is described. Neither this nor the  $\text{C}_5\text{H}_5\text{N}$  method is successful for 1:8- $\text{C}_{10}\text{H}_6\text{Br}\cdot\text{SO}_3\text{H}$ ; its *chloride*, m.p.  $110^\circ$ , is, however, obtained by adding the solid diazo-compound to the cold suspension obtained after boiling  $\text{Cu}_2\text{O}$  in aq.  $\text{NH}_4\text{Br}$ , by adding KCl, and treating the product with  $\text{PCl}_5$ . By adding the diazo-compound to  $\text{CuCN}$ , 1:8- $\text{CN}\cdot\text{C}_{10}\text{H}_6\cdot\text{SO}_3\text{H}$  is obtained (*chloride*, m.p.  $139^\circ$ ; *amide*, m.p.  $334\text{--}336^\circ$ ). The diazo-compound treated with Cu in conc. HCl, with Cu in  $\text{Cu}_2\text{Cl}_2\text{--HCl}$ , with  $\text{Sn}(\text{OH})_2$ , or with Zn in  $\text{H}_2\text{O}$  gives 1- $\text{C}_{10}\text{H}_7\cdot\text{SO}_3\text{H}$ . The diazo-compound from 2:1- $\text{NH}_2\cdot\text{C}_{10}\text{H}_6\cdot\text{SO}_3\text{Na}$  and KI, followed by KOH, gives the K salt (+ $\text{H}_2\text{O}$ ) of 2:1- $\text{C}_{10}\text{H}_6\text{I}\cdot\text{SO}_3\text{H}$  (*chloride*, m.p.  $109.5^\circ$ ; *amide*, m.p.  $154^\circ$ ); with the suspension from  $\text{Cu}_2\text{O}$  and  $\text{NH}_4\text{Br}$ , followed by KCl, the K salt of 2:1- $\text{C}_{10}\text{H}_6\text{Br}\cdot\text{SO}_3\text{H}$  (*chloride*, m.p.  $97^\circ$ ; *amide*, m.p.  $140^\circ$ ) is obtained. 1:4-, 1:5-, and 1:8- $\text{C}_{10}\text{H}_6(\text{SO}_3\text{H})_2$  have been identified among the respective reaction products of the diazo-compounds from 1:4-, 1:5-, and 1:8- $\text{NH}_2\cdot\text{C}_{10}\text{H}_6\cdot\text{SO}_3\text{H}$  and a solution of  $\text{CuSO}_4$  in aq.  $\text{NH}_3$ , treated with  $\text{SO}_2$ . E. W. W.

**Carbonitrosohydrazines. IV. Azohydroxamic acids [and hydrochloric acid]** A. QUILICO and R. JUSTONI (Gazzetta, 1936, 66, 19—22; cf. A., 1935, 855).—When p-chlorobenzene- and p-toluene-azoformhydroxamic acids are boiled with conc. HCl, they are chlorinated in the nucleus and reduced, yielding, respectively, 2:4-dichlorobenzene-, m.p.  $184\text{--}185^\circ$ , and 2-chloro-p-toluene-hydrazoformhydroxamic acid, m.p.  $169^\circ$ , which are reduced respectively to 2:4-dichloroaniline and 2-chloro-p-toluidine. E. W. W.

**Influence of cyclisation on "colour" of molecules. Absorption of diphenyleneazone and its mono- and di-oxides.** (MME.) P. RAMART-LUCAS and (MLE.) D. BIQUARD (Bull. Soc. chim., 1936, [v], 3, 430—435).—Comparison of the absorption spectra of  $(\text{NPh})_2$  and diphenyleneazone (I) (Tauber, A., 1892, 183) shows that, unlike the case of carbocyclic compounds, cyclisation is accompanied by a marked hypsochromic effect and a diminution in absorption intensity (ascribed to deformation of the valency angles). The curves for axoxybenzene (II) and the mono- and di-oxides of (I) show little difference. The absorption intensity of o-azoxytoluene is < that of (II). H. B.

**Velocity of diazotation.** E. ROSTOV-TZEVA (Anilinokras. Prom., 1935, 5, 199—201).—The velocity of diazotisation of aromatic amines is determined relatively to that of benzidine, giving a series of characteristic ratios  $k/k_1$ , where  $k$  and  $k_1$  are the respective velocity coeffs. The content of each con-

stituent in binary mixtures of isomeric amines can be derived from determination of  $k_1/k$  for the mixture.

R. T.

**Electronic theory of valency and the constitution of aromatic diazo-compounds.** P. B. SARKAR (J. Indian Chem. Soc., 1936, 13, 19—22).—Theoretical. The structure of diazonium compounds and of normal and *iso*-diazotates can be explained by electronic theory.

F. R. G.

**$\alpha$ - and  $\beta$ -Anthracenediazonium salts.** M. BATEGAY and P. BOEHLER (Compt. rend., 1936, 202, 769—771).— $\beta$ -Anthramine hydrochloride at 0° affords a sol. diazonium chloride (+ $ZnCl_2$ , decomp. about 105°; + $CdCl_2$ ), which is decomposed by light. The  $\alpha$ -isomeride (+ $ZnCl_2$ , decomp. about 100°) is similar.

J. L. D.

**Phosphoric acid as a condensing agent.** A. E. TSCHITSCHIBABIN (Bull. Acad. Sci. U.R.S.S., 1935, 951—969).—Alkylation of phenols is readily effected by heating mixtures of the alcohol, the phenol, and  $H_3PO_4$ . Thus, *o*-tert.-butyl-*m*-cresol, b.p. 121—122°/16 mm., m.p. 23°, is obtained from  $Bu^tOH$ , *o*-cresol, and  $H_3PO_4$  at 50°; *o*-sec.-butyl-, b.p. 111—116°/12 mm., *o*-tert.-amyl-, b.p. 119—122°/10 mm., and *o*-menthyl-*m*-cresol, b.p. 153—156°/2.5 mm., *o*-tert.-butyl-, b.p. 122.5°/14 mm., m.p. 27° (lit. 85—86°), and *o*- and *p*-benzyl-*o*-cresol, *o*-tert.-butyl-*p*-cresol, b.p. 118—119°/14 mm., m.p. 44°, *o*-tert.-butyl-, b.p. 125.5—126°/17 mm., and *o*-isopropyl-*m*-xyleneol, b.p. 127—130°/17 mm., tert.-butyl- $\beta$ -naphthol, b.p. 186—189°/13 mm., m.p. 113°, 4-tert.-butyl-, b.p. 134—136°/1.5 mm. ( $Me_2$  ether, b.p. 126—129°/13 mm., m.p. 4°), and 4:6-di-tert.-butyl-resorcinol, m.p. 121° ( $Me_2$  ether, b.p. 136—140°/13 mm., m.p. 76°), are obtained analogously. *m*-Cresol and octene yield *o*-octyl-*m*-cresol, b.p. 153—154°/11 mm., and  $PhOH$  and allyl alcohol afford *o*-propenylphenol, b.p. 200—205°.

R. T.

**Condensation of aliphatic alcohols with aromatic compounds in presence of aluminium chloride.** I. R. C. HUSTON and T. Y. HSIEH (J. Amer. Chem. Soc., 1936, 58, 439—441).— $CHAlk_2OH$  (1 equiv.) added to a well-stirred mixture of  $C_6H_6$  (2—5 equivs.) and  $AlCl_3$  (0.5 equiv.) at < 30° gives 25—28% of  $CHPhAlk_2$ ;  $PhPr^s$ ,  $CHPhMeEt$ ,  $CHPhMePr^s$ , and  $CHPhMePr^s$  are thus prepared.  $Bu^tOH$  similarly affords 67% of  $PhBu^t$  whilst  $CH_2AlkOH$  (I) do not react.  $Alk_3OH$  (0.25 mol.),  $PhOH$  (0.25 mol.), and  $AlCl_3$  (0.125 mol.) in light petroleum at 25—30° give 45—60% of  $p-OH-C_6H_4Alk_3$ ; (I) ( $Alk=Me-Pr$ ) and *sec*.- $BuOH$  do not react, whilst  $Pr^sOH$  affords a small amount of an unidentified product. The following are described:  $p-C_6H_4Bu^tOH$  (benzenesulphonate, m.p. 70—71°; *p*-toluenesulphonate, m.p. 109—110°); *p*-tert.-amylphenol (benzenesulphonate, b.p. 184—185°/3 mm.; *p*-toluenesulphonate, m.p. 54—55°);  $\beta$ -*p*-hydroxyphenyl- $\beta$ -methylpentane (II), b.p. 259—261°/740 mm., m.p. 37—38° (from  $CMe_2Pr^sOH$ ) (benzoate, b.p. 169—171°/3 mm.; benzenesulphonate, b.p. 174—175°/3 mm.; *p*-toluenesulphonate, b.p. 194—195°/3 mm.);  $\beta$ -*p*-hydroxyphenyl- $\beta$ -*γ*-dimethylbutane (III), b.p. 266—268°/740 mm., m.p. 105—106° (from  $CMe_2Pr^sOH$ ) (benzoate, m.p. 54—55°; benzenesulphonate, b.p. 178—179°/3

mm.; *p*-toluenesulphonate, b.p. 187—188°/3 mm.);  $\gamma$ -*p*-hydroxyphenyl- $\gamma$ -methylpentane (IV), b.p. 268—269°/740 mm., m.p. 59—60° (from  $CMeEt_2OH$ ) (benzoate, m.p. 77—78°; benzenesulphonate, b.p. 183—184°/3 mm.; *p*-toluenesulphonate, b.p. 188—189°/3 mm.).  $CPhMe_2Pr^s$ ,  $CPhMe_2Pr^s$ , and  $CPhMeEt_2$  with  $HNO_3$  (*d* 1.52) at room temp. give the *p*- $NO_2$ -derivatives, b.p. 124—126°/3 mm., 122—124°/3 mm., and 123—125°/3 mm., respectively [which are all oxidised by  $HNO_3$  (*d* 1.2) at 130° to  $p-NO_2-C_6H_4CO_2H$ ], reduced (Sn, conc.  $HCl$ ) to the *p*- $NH_2$ -derivatives, b.p. 107—109°/3 mm., 109—111°/3 mm., and 108—110°/3 mm., respectively, which are then converted (diazo-method) into (II), (III), and (IV), respectively.

H. B.

**Comparative acetylation of naphthols.** A. LEMAN (Compt. rend., 1936, 202, 579—581; see A., 1935, 856).—The order of the reactivity of the OH towards  $Ac_2O$  in  $C_5H_5N$  solution is  $\alpha$ - and  $\beta$ - $C_{10}H_7OH > 1:5 > 1:7$ - $C_{10}H_6(OH)_2$ . In  $AcOH$  solution the order is  $\beta$ - $C_{10}H_7OH > 1:7$ - $C_{10}H_6(OH)_2 > \alpha$ - $C_{10}H_7OH$  and  $1:5$ - $C_{10}H_6(OH)_2$ .

J. N. A.

**Interaction of groups in the same molecule.** J. BOESEKEN, P. C. HENRIQUEZ, and J. J. VAN DER SPEK (Rec. trav. chim., 1936, 55, 145—152).—Factors, especially abnormal dipole moments ( $\mu$ ), pointing to mutual influences of groups in the same mol. are reviewed.  $\mu$  of pyrocatechol cyclic ethers is determined, and is as follows: *o*-methylene-, 1.0; *o*-isopropylidene-, 1.02; *o*- $\alpha$ -phenylethylidene-, 1.05; and 4-bromo-, 2.70; 4-chloro-, 2.74; 4:5-dibromo-, 3.28; and 4:5-dichloro-*o*-methylene-dioxybenzene, 3.39. These vals. are much > those calc. by vectorial addition, on the assumption that the total moment is in the normal direction, and slightly > those calc. on the converse assumption. Thus there is a strong mutual interaction, either between the ether groups and the halogen atoms, or between the moments which constitute a part of the 5-ring.

E. W. W.

**Bromo-derivatives of pyrocatechol.** J. FREJKA and B. ŠEFRÁNAK (Coll. Czech. Chem. Comm., 1936, 8, 130—139).— $o-C_6H_4(OH)_2$  (I) with Br (4 mols.) in cold  $CHCl_3$  or, better, in conc.  $H_2SO_4$ , gives its  $Br_2$  derivative, m.p. 191—192°. Lit. methods fail to give the 3:4:5- $Br_3$ -derivative (II), m.p. 144° (corr.), which is obtained by the action of  $Br-CHCl_3$  or Br vapour on a 3%  $CHCl_3$  solution of (I) at < 20° (monohydrate could not be obtained;  $Ac_2$  derivative, m.p. 120°), characterised by conversion ( $MeI-MeOH-K_2CO_3$ ) into its known  $Me_2$  ether. With Br (2 mols.)- $AcOH$  a 22% solution of (I) in  $AcOH$  (Cousin, A., 1895, i, 456) or  $CO_2-Br$  vapour into (I)- $CHCl_3$ , gives the 4:5- $Br_2$ -derivative (III), but if  $SO_2-Br$  vapour is passed into (I)- $CHCl_3$  at room temp. an 80% yield of the 3:4- $Br_2$ -derivative, m.p. 73—74° ( $Ac_2$  derivative, m.p. 95—96°) [converted by  $Br-CHCl_3$  into (II)], is obtained. (III) is not obtained by the method of Kohn *et al.* (A., 1927, 966), which gives only a mixture, possibly containing the 3:6- $Br_2$ -derivative, m.p. 120° ( $Ac$  derivative, m.p. about 170°), which could not be isolated pure.

J. W. B.

**$\beta$ -Phenyl sulphide.** O. HINSBERG (Ber., 1936, 69, [B], 492—495; cf. A., 1929, 310).—The yield of  $\beta$ -Ph (isophenyl) sulphide (I) is greatly increased when

the action of  $\text{HClO}_4$  on  $\alpha$ -Ph sulphide (II) is effected in considerable amounts of  $\text{AcOH}$  or  $\text{EtCO}_2\text{H}$ . The product is treated with  $\text{MeOH-KOH}$  and light petroleum and (I), b.p.  $324-329^\circ/\text{atm. pressure}$ , is readily isolated by fractional distillation of the petroleum extract. (I) is not isomerised to (II) when repeatedly distilled or heated at  $290-300^\circ$  in a sealed tube, but transformation occurs when it is boiled with  $\text{P}_2\text{O}_5$ . (I) is transformed at  $16^\circ$  by  $\text{HClO}_4$  into its perchlorate, which is produced from diphenylsulphonium hydr-oxide (III) and  $\text{HClO}_4$  in  $\text{AcOH}$  at room temp., thus indicating a constitutive change during the transformation of (I) into (III). The residues from the distillation of (I) contain *diphenylphenylene disulphide*,  $\text{C}_6\text{H}_4(\text{SPh})_2$ , m.p.  $80^\circ$ , converted by  $\text{H}_2\text{O}_2$  in  $\text{AcOH}$  into the corresponding *disulphone*, m.p.  $229^\circ$ . (II) and  $\text{HClO}_4$  in boiling  $\text{MeOH}$  afford  $\alpha$ -*diphenylmethylsulphonium perchlorate*,  $\text{SPh}_2\text{Me}\cdot\text{ClO}_4$ , m.p.  $76^\circ$ , which breaks down in warm  $\text{EtOH}$  containing  $\text{KOAc}$  into (I),  $\text{KClO}_4$ , and  $\text{MeOH}$ .  $\beta$ -*Diphenylmethylsulphonium perchlorate*, which does not solidify at  $-10^\circ$ , and *phenyldimethylsulphonium perchlorate*, m.p.  $160^\circ$ , are obtained analogously. H. W.

**cycloHexene peroxide.** H. HOCK and O. SCHRADER (Naturwiss., 1936, 24, 159; cf. Stephens, A., 1928, 401).—Irradiation of *cyclohexene* in  $\text{O}_2$  yields 20% of the peroxide (I), isolated (96% purity) by distillation in high vac.; presence of eosin doubles the velocity of reaction. Treatment of (I) with  $1-2N\text{-H}_2\text{SO}_4$  affords 50% of *cis-cyclohexane-1:2-diol*, m.p.  $104^\circ$ , and 10–20% of *cyclopentenaldehyde (semicarbazide)*, m.p.  $208^\circ$  and with conc.  $\text{NaOH}$   $\Delta^1$ -*cyclohexen-3-ol (naphthylurethane)*, m.p.  $156^\circ$  [also afforded by reduction of (I) with aq.  $\text{Na}_2\text{SO}_3$ ]. F. O. H.

**Osmic acid esters as intermediate products in oxidations.** R. CRIGEE (Annalen, 1936, 522, 75–96).—Böeseken's view (cf. A., 1920, ii, 219) that the production of *cis*-diols from olefines and  $\text{NaClO}_3$  in presence of a little  $\text{OsO}_4$  (Hofmann, A., 1913, ii, 62, 609) occurs through the intermediate ester,

$\text{R}\begin{matrix} \text{CH}\cdot\text{O} \\ \diagup \\ \text{CH}\cdot\text{O} \end{matrix}\text{OsO}_2$ , is proved by the following results.

Such esters (decomp. temp. quoted after substance) are prepared from acenaphthylene (I),  $236^\circ$ , indene,  $204^\circ$ , 1:4-dihydronaphthalene,  $170^\circ$ , and  $\Delta^9$ -octahydronaphthalene,  $200^\circ$ , in 89–99% yield by treatment with an equiv. of  $\text{OsO}_4$  in abs.  $\text{Et}_2\text{O}$ . These are converted by oxidative hydrolysis ( $M/3\text{-NaClO}_3$  in dioxan- $\text{AcOH}$ ) or, better, by reductive hydrolysis (aq.  $\text{EtOH-Na}_2\text{SO}_3$ ) [whereby the insol. salt,  $\text{Na}_4\text{Os}(\text{SO}_3)_3\cdot 6\text{H}_2\text{O}$ , is also produced] into *cis*-7:8-dihydroxyacenaphthene (II), *cis*-1:2-dihydroxyindane (III), *cis*-2:3-dihydroxy-1:2:3:4-tetrahydronaphthalene, and *cis*-9:10-dihydroxydecahydronaphthalene, m.p.  $89.5^\circ$  [oxidised by  $\text{Pb}(\text{OAc})_4$  in  $\text{C}_6\text{H}_6$  to *cyclo-decane-1:6-dione* (Hückel *et al.*, A., 1930, 76)], respectively. The above ester from (I) forms a 1:2-additive compound with  $\text{C}_5\text{H}_5\text{N}$ ; this is converted by warm  $\text{AcOH}$  or  $0.2N\text{-NaOH}$  in  $\text{H}_2$  (and subsequent acidification) into the diester (IV), 1:8- $\text{C}_{10}\text{H}_6\begin{matrix} \text{CH}\cdot\text{O} \\ \diagup \\ \text{CH}\cdot\text{O} \end{matrix}\text{OsO}\begin{matrix} \text{O}\cdot\text{CH} \\ \diagdown \\ \text{O}\cdot\text{CH} \end{matrix}\text{C}_{10}\text{H}_6$ -1:8, decomp.  $292^\circ$  [ $\text{K}_2$  salt (+ $4\text{H}_2\text{O}$ )], also obtained (a) on attempted hydrolysis ( $\text{H}_2\text{O}$  or  $\text{EtOH-HCl}$  in dioxan; alkali

followed by  $\text{CO}_2$ ) of the original ester, (b) from the ester and (II), (III), or *cis-cyclohexanediol* (V) in dioxan, and (c) from (II) and  $\text{K}_2\text{OsO}_4$  in 1%  $\text{KOH}$  followed by dil.  $\text{AcOH}$ . Analogous diesters are also prepared [method (c)] from *cis*-7:8-dihydroxy-7:8-diphenylacenaphthene (VI), decomp.  $274^\circ$ , (III), decomp.  $204^\circ$ , (V), decomp.  $165^\circ$ , ( $\text{CMe}_2\cdot\text{OH}$ ) $_2$ , decomp.  $197^\circ$ , and  $\beta$ -anethole glycol, decomp.  $171^\circ$ ; esters could not be prepared from *trans*-diols. Similar diesters (as  $\text{K}_2$  salts) are obtained from hydrobenzoin and isohydrobenzoin. The monoester from (I) with (VI) (but not the *trans*-isomeride) gives a mixed diester of (II) and (VI) together with smaller amounts of (IV) and the above diester of (VI). Os in the above compounds is determined by oxidation with  $\text{CrO}_3$ +conc.  $\text{H}_2\text{SO}_4$ ; the  $\text{OsO}_4$  formed is distilled into a mixture of  $0.4N\text{-KI}$ ,  $2N\text{-H}_2\text{SO}_4$ , and  $\text{CHCl}_3$ , and then titrated with  $\text{Na}_2\text{S}_2\text{O}_3$ .

*cycloHexene* (VII) in  $\text{O}_2$  and sunlight yields  $\Delta^2$ -*cyclohexenyl H peroxide* (VIII); in presence of, e.g.,  $\text{OsO}_2$ , which is oxidised by (VIII) to  $\text{OsO}_4$ , the following reactions occur:  $(\text{VII}) + \text{OsO}_4 \rightarrow \text{C}_6\text{H}_8\begin{matrix} \text{CH}\cdot\text{O} \\ \diagup \\ \text{CH}\cdot\text{O} \end{matrix}\text{OsO}_2$ , which is then oxidised by (VIII) to  $(\text{CH}_2)_4(\text{CHO})_2$ ; (VIII) is thus reduced to *cyclohexenol*. Willstätter and Sonnenfeld's results (A., 1913, i, 1200) on the autoxidation of (VII) in presence of Os and  $\text{OsO}_2$  are thus satisfactorily explained.

[With W. RICHTER.] The esters  $\begin{matrix} \text{CHR}\cdot\text{O} \\ \diagup \\ \text{CHR}\cdot\text{O} \end{matrix}\text{OsO}_2$ , when treated with  $\text{H}_2\text{O}_2$  in absence of  $\text{H}_2\text{O}$  undergo oxidative fission to  $\text{RCHO}$ ,  $\text{R'CHO}$ , and  $\text{OsO}_3$  (which then gives  $\text{OsO}_4$ ). Thus stilbene,  $\text{H}_2\text{O}_2$ , and a little  $\text{OsO}_4$  in  $\text{Et}_2\text{O}$ +anhyd.  $\text{Na}_2\text{SO}_4$  give 77% of  $\text{PhCHO}$  and a little  $\text{BzOH}$ . Anethole, *isoeugenol* Me ether, *isocugenol* acetate, and *isosafrole* similarly afford  $\text{MeCHO}$  (54–98%) and *p*- $\text{OME}\cdot\text{C}_6\text{H}_4\cdot\text{CHO}$ , veratraldehyde, acetylvanillin, and piperonal, respectively, in 47–75% yield; small amounts of the corresponding  $\text{ArCO}_2\text{H}$  are also produced. H. B.

**Constitution of dihydrovitamin- $D_2$ .** S. VON REICHEL and M. DEPPE (Z. physiol. Chem., 1936, 239, 143–146; cf. this vol., 69).—The allophanate of dihydrovitamin- $D_2$  (I) in  $\text{CHCl}_3$  gives, with  $\text{BzO}_2\text{H}$ ,

the trioxide (II), m.p.  $190^\circ$ ,  $[\alpha]_D^{19} -3.4^\circ$  in  $\text{CHCl}_3$ , 3 O being taken up. (II) with  $\text{CrO}_3$  in  $\text{AcOH}$  gives a monocarboxylic acid (III), m.p.  $219^\circ$ ,  $[\alpha]_D^{20} -23.3^\circ$  in  $\text{AcOH}$ , which yields the *OH-acid*,  $\text{C}_{22}\text{H}_{34}\text{O}_6$ , m.p.  $244^\circ$  (Me ester, m.p.  $216^\circ$ , and its acetate, m.p.  $155-156^\circ$ ,  $[\alpha]_D^{19} -55^\circ$ ), when boiled with  $\text{KOH}$  in  $\text{EtOH}$  and gives the  $\text{CHI}_3$  reaction, but does not react with  $\text{NH}_2\text{OH}$  or semicarbazide or absorb ultra-violet light. The oxidation yields also a neutral substance,  $\text{C}_{30}\text{H}_{48}\text{O}_8\text{N}_2$ , m.p.  $239-240^\circ$ ,  $[\alpha]_D^{20} -68.2^\circ$  in  $\text{CHCl}_3$ , which does not

absorb ultra-violet light. When (II) in  $\text{CHCl}_3$  is treated with  $\text{O}_3$  and the product oxidised with  $\text{CrO}_3$

in AcOH (III) is produced. The structures A and B are therefore assigned to (III) and (I), respectively.

W. McC.

**Sterols. IV. Androsterone derivatives.** R. E. MARKER. **V. epiCholesterol.** R. E. MARKER, T. S. OAKWOOD, and H. M. CROOKS (J. Amer. Chem. Soc., 1936, 58, 480—481, 481—483).—IV. Reduction (Na, amyl alcohol) of androsterone-oxime gives 17-aminoandrosterone [hydrochloride, m.p. 340° (decomp.)], converted (diazotization) into 3:17-androstanediol, m.p. 218—220°, which, like isoandrosterone, is oxidised ( $\text{CrO}_3$ , AcOH) to 3:17-androstanedione, m.p. 128—129°. Similar reduction of the oxime of  $\alpha$ -3-chloroandrosterone (I) affords 17-aminoandrosterone [hydrochloride, m.p. 345° (decomp.)], converted into 17-androstanol, m.p. 166°, which is also prepared by reduction of (I).

V. Cholesteryl chloride and Mg give Mg dl-cholesteryl chloride (II), which with dry  $\text{O}_2$  at  $-7^\circ$  to  $0^\circ$  affords cholesterol and epicholesterol (III), m.p. 141°, not pptd. by digitonin. Reduction ( $\text{H}_2$ ,  $\text{PtO}_2$ ,  $\text{Et}_2\text{O}$ ) of (III) gives a quant. yield of epicholesterol, thus showing the presence of the  $\Delta^{5:6}$  double linking. (II) and  $\text{CO}_2$  at  $0^\circ$  afford dl- $\Delta^5$ -cholestene-3-carboxylic acid, m.p. 222—225° (Me, m.p. 101.5—102.5°, and Et, m.p. 82.5—83°, esters), reduced ( $\text{H}_2$ ,  $\text{PtO}_2$ ,  $\text{Et}_2\text{O}$ -AcOH) to dl-cholestane-3-carboxylic acid, m.p. 209—211° (Me, m.p. 70—71°, and Et, m.p. 66.5—67.5°, esters). Cholesteryl bromide similarly affords Mg dl-cholesteryl bromide.

H. B.

**Thermal decomposition of diacyl peroxides.** H. ERLÉNMEYER and W. SCHOENAUER (Helv. Chim. Acta, 1936, 19, 338—342).—Contrary to Wieland *et al.* (A., 1934, 1215), decomp. of  $\text{Bz}_2\text{O}_2$  gives  $\text{C}_6\text{H}_6$  even in vac. and none of the products necessarily involves the intermediate formation of free radicals. Disproportionation is preferred as a general explanation of the reactions occurring.

R. S. C.

**Alleged dihydrophenylbenzamidine.** A. V. KIRSANOV (Bull. Acad. Sci. U.R.S.S., 1935, No. 6—7, 979—984).—Phenylbenzamidine (I) and Na-Hg react as follows: (I) +  $2\text{H} \rightarrow \text{NH}_2\cdot\text{CHPh}\cdot\text{NHPh}$  (II)  $\rightarrow \text{NH}_3 + \text{CHPh}\cdot\text{NHPh}$  (III); (III) +  $\text{H}_2\text{O} \rightarrow \text{PhCHO} + \text{NH}_2\text{Ph}$ ; (III) +  $2\text{H} \rightarrow \text{CH}_2\text{Ph}\cdot\text{NHPh}$ ; (II)  $\rightarrow \text{NH}_2\text{Ph} + \text{CHPh}\cdot\text{NH}$  (IV); (IV) +  $2\text{H} \rightarrow \text{NH}_2\cdot\text{CH}_2\text{Ph}$ . (II) cannot be isolated from the reaction products, and probably decomposes immediately on formation; the product identified as (II) by Bernthsen *et al.* (A., 1880, 639) was probably unchanged (I).

R. T.

**Hexadeuterobenzene and a trideuterobenzoic acid.** H. ERLÉNMEYER, H. LOBECK, H. GÄRTNER, and A. EPPRECHT (Helv. Chim. Acta, 1936, 19,

336—337; cf. this vol., 61).—Hexadeuterobenzene of constitution  $\text{C}_6\text{D}_{5.59}\text{H}_{0.41}$  has b.p.  $79.4^\circ$ , m.p.  $6.8^\circ$ ,  $d_4^{20}$  0.9465,  $n_D^{20}$  1.4997. With  $\text{ClCO}\cdot\text{NH}_2$  and  $\text{AlCl}_3$  in  $\text{CS}_2$ , followed by decomp. of the complex with  $\text{H}_2\text{O}$ , this gives a benzamide, which, when hydrolysed, affords a nearly pure trideuterobenzoic acid,  $\text{C}_6\text{H}_{2.91}\text{H}_{2.08}\cdot\text{CO}_2\text{H}$ , m.p.  $121.3^\circ$ . The positions of the 3 D are unknown.

R. S. C.

**Asymmetric carbon atom, CHDRR'. II. Attempted resolution of a deuterio- $\beta$ -phenylpropionic acid.** H. ERLÉNMEYER and H. GÄRTNER (Helv. Chim. Acta, 1936, 19, 331—335; cf. this vol., 467).— $\text{C}_6\text{H}_2.18\text{D}_{2.82}\cdot\text{C}_2\text{H}_{1.62}\text{D}_{2.38}\cdot\text{CO}_2\text{H}$  could not be resolved by strychnine.

R. S. C.

**Mechanism of Perkin's reaction.** D. A. BRODSKI (Monatsh., 1936, 67, 137—140).—The study (A., 1933, 392) of the effect of NaOAc on the yield of  $\text{CHPh}\cdot\text{CH}\cdot\text{CO}_2\text{H}$  (I) in Perkin's synthesis was overlooked by Böck *et al.* (A., 1934, 1348). The modes of formation and decomp. of  $\text{CHPh}(\text{OAc})_2$  are not considered to accord with their conclusion that it is involved in a side-reaction detrimental to the yield of (I).

H. G. M.

**Tafel rearrangement. II. Electrochemical reduction of ethyl cyclopentanecarboxylate.** H. STENZL, F. FICHTER, and H. ARNI (Helv. Chim. Acta, 1936, 19, 392—398; cf. A., 1934, 631).—Cathodic reduction of Et cyclopentanone-2-carboxylate gives cyclohexanol and some Et cyclopentane- and cyclopentan-2-carboxylate and Et, 1:1'-dihydroxy-1:1'-dicyclopentan-2:2'-dicarboxylate, m.p.  $108^\circ$  (corresponding acid, decomp.  $230^\circ$ ), which favours interpretation of the Tafel rearrangement by migration of acyl. Reduction of  $\text{CO}_2\text{Et}$  occurs only before the CO is reduced and is accompanied by migration of COR.

R. S. C.

**Synthetic substances resembling thyroxine from diphenyl ether.** K. H. SLOTTA and K. H. SOREMBÄ (Ber., 1936, 69, [B], 566—572).— $\text{p-OPh}\cdot\text{C}_6\text{H}_4\cdot\text{CHO}$  and  $\text{MeNO}_2$  in EtOH are converted by KOH in  $\text{MeOH}\cdot\text{H}_2\text{O}$  at  $0^\circ$  into  $\omega$ -nitro-p-phenoxy-styrene, m.p.  $102^\circ$ , electrolytically reduced in EtOH-EtOAc-HCl to  $\beta$ -p-phenoxyphenylethylamine hydrochloride (I), m.p. 209—210°.  $\text{p-OPh}\cdot\text{C}_6\text{H}_4\cdot\text{CHO}$  is transformed by KCN and  $(\text{NH}_4)_2\text{CO}_3$  in EtOH- $\text{H}_2\text{O}$  at  $80^\circ/10$ —12 atm. ( $\text{CO}_2$ ) into 5-p-phenoxyphenylhydantoin, m.p. 203—204°, hydrolysed by boiling 21% KOH to p-phenoxyphenylaminoacetic acid (II), m.p.  $242^\circ$  [hydrochloride, (III), m.p. 218—220° (decomp.)]. Hippuric acid, NaOAc,  $\text{p-OPh}\cdot\text{C}_6\text{H}_4\cdot\text{CHO}$ , and  $\text{Ac}_2\text{O}$  at  $100^\circ$  afford the azlactone,

$\text{CPh}\cdot\text{N} \begin{array}{c} \diagup \\ \text{O}-\text{CO} \end{array} \text{C}\cdot\text{CH}\cdot\text{C}_6\text{H}_4\cdot\text{OPh}$ , m.p.  $158^\circ$ , hydrolysed to  $\alpha$ -benzamido- $\beta$ -p-phenoxyphenylacrylic acid, m.p. 188—189°, which is converted by red P, HI ( $d$  1.7), and  $\text{Ac}_2\text{O}$  into  $\alpha$ -amino- $\beta$ -p-phenoxyphenylpropionic acid (IV) (deiododeoxythyroxine), m.p.  $247^\circ$  when rapidly heated [hydrochloride (V), m.p. 218—220° (decomp.)]. Similarly  $\text{p}'\cdot\text{C}_6\text{H}_4\cdot\text{I}\cdot\text{O}\cdot\text{C}_6\text{H}_4\cdot\text{CHO}$  gives successively the azlactone,  $\text{C}_{22}\text{H}_{14}\text{O}_3\text{NI}$ , m.p. 158—159°,  $\alpha$ -benzamido- $\beta$ -p-4'-iodophenoxyphenylacrylic acid, m.p. 222—223°, and  $\alpha$ -amino- $\beta$ -p-4'-iodophenoxyphenylpropionic acid (VI), m.p. 249—250°.

$p'$ -NO<sub>2</sub>·C<sub>6</sub>H<sub>4</sub>·O·C<sub>6</sub>H<sub>4</sub>·CHO gives the *azlactone*, C<sub>22</sub>H<sub>14</sub>O<sub>5</sub>N<sub>2</sub>, m.p. 177°,  $\alpha$ -benzamido- $\beta$ -p-4'-nitrophenoxypheylacrylic acid, m.p. 210°, and  $\alpha$ -amino- $\beta$ -p-4'-aminophenoxyphenylpropionic acid (VII), m.p. 239—240° [hydrochloride, m.p. 270—275° (strong decomp.)]. Treatment of (III) with ICl in AcOH gives the *iodo-derivative*, m.p. 238—240°. Iodination of (IV) could not be effected by I and NaOH, I, KI, and conc. NH<sub>3</sub>, or by ICl in 2*N*-HCl whereas (V) with ICl in AcOH yields (VI) [hydrochloride, m.p. 235—240° (decomp.)]. No physiological activity is shown by (I), (II), (IV), (VI), or (VII). H. W.
